panies to the extent of making detailed exploration with drills? There is a solution, and a fair one. Many land-owners have reason to believe that mineral is present on their land in sufficient quantities and of high enough grade to warrant a mining company spending a thousand dollars or so in drilling. Such an owner should be willing, himself, to invest two or three hundred dollars in making preliminary investigation. Suppose he, the land-owner, puts down two or three holes on his farm and finds 'jack' in attractive quantities. It would then be an easy matter for him to get any operator to proceed with exploration work. Such small investment would surely be worth while in view of the possibility of the enormous royalties that would be paid to the land-owner if a mine is developed. In reality it is a matter of competition among land-owners. A farm favorably situated or partly prospected has a great advantage over a poorly placed one. Do the owners of prospective mining properties realize that this competitive condition exists? With a state mining school in the district, any land-owner has at his command expert advice to guide him in doing this preliminary prospecting. It is possible to have records made and kept, showing the progress of drilling operations. The owner of property may be certain as to the authenticity of these records and likewise he has a record to show the prospective operator which can be considered absolutely reliable.

Another difficulty exists in this district that can be met if the mine operator and land owner look at it in a fair manner. The cost of mining a ton of crude ore and bringing it to the mill for concentration is the same whether the amount of mineral is great or small, and whether the grade of concentrate produced is high or low. These questions of amount of mineral in crude ore and grade of con-

centrate are the vital ones, and make for profit or loss. It is clear that a property in which the ground is lean cannot operate at a profit and pay as high a royalty as one in which the ground is rich. Likewise, a mine selling a low-grade concentrate cannot in many cases receive a sufficient price per ton for the ore to cover operating cost and still pay the same royalty as a mine producing a high-grade concentrate. Would it not be better to institute a sliding scale of royalty to be determined both by the richness of the ground and the grade of concentrate, rather than fix the royalty rate arbitrarily and thereby prohibit operations at a profit? It would be better to receive a royalty suited to the character of the ground rather than to eliminate operations entirely and thus 'kill the goose that lays the golden eggs.'

A condition also exists in the Wisconsin zinc district that must be remedied by the railroad companies. Such remedy can only be brought about by the concerted action and activities of the community as a whole. Railroad facilities are inadequate, and on account of this the operators of the zinc mines are greatly hampered. It is an undeniable fact that all the large operators could, with better condition of train service, prospect and develop fully half again as many properties as they are now directing. The community in general must cope with this condition if it is anxious for increased development of the mining industry.

Power on the Rand

At the present time the Victoria Falls Power Co. has three stations supplying power to the mines; one at Brakpan, another at Simmer Pan near Germiston, and the third at Rosherville, midway between Germiston and Johannesburg. A large power-station is also being constructed at Vereeniging, some thirty miles south of Johannesburg. To give an idea of these stations, a short description of the Rosherville plant, the largest in use, may be interesting. The steam is supplied by 24 Babcock & Wilcox boilers, marine type, fitted with superheaters, chain-grate stokers, and Pratt's system of induced draft. The fuel used is the dust coal from collieries in the Middelburg district, which was formerly regarded and treated as waste. The actual evaporative power of this cheap fuel is $6\frac{1}{2}$ lb. of water to one of coal. The boiler pressure is 220 lb. per square inch, and the evaporating capacity of each boiler 30,000 lb. per hour. There are five turbo-generators, each of 12,000 k.v.a. capacity, running at a speed of 1000 r.p.m., designed to deliver 3-phase current at a frequency of 50 periods per second, with a pressure of 5000 volts at the machine terminals. The turbines work with steam superheated at 350°C . and are connected to surface condensers placed immediately below the exhaust end of the turbine. The air-compressors are of the rotary type, driven by direct-coupled turbines, running at a normal speed of 3000 r.p.m., capable of converting 590 cubic metres of free air to an absolute pressure of nine atmospheres. The compressors are multi-stage, divided into high and low-pressure cylinders, the air being led through a cooler when passing from the low-pressure to the high-pressure cylinder. The electrical supply is sent out at two pressures, 20,000 volts through underground cables and 40,000 v. by overhead lines. These pressures are obtained from Siemen's transformers, each of 12,500 k.v.a. capacity, which receive current from the generators at 5000 v. and deliver it to the main bus-bars at 20,000 or 40,000 v., as may be required. Coupling transformers are provided between the 20,000 and 40,000-v. bus-bars for the regulation of supply. All switches are operated by a remote control from the main operating board which overlooks the turbine-room. The Rosherville power station here described is the largest in capacity of any of the three stations at present run by the Victoria Falls Power Co., but the Vereeniging station now in course of erection will surpass it. The demand for power at the mines has, however, so far exceeded anticipations that preparations are being made to considerably extend the Rosherville power station. The whole

of the power generated by the three stations of the company is, in its distribution over the Rand, entirely and solely controlled from the Simmer Pan station.

The scale of prices charged to consumers is as follows:

Load factor. Percentage.	Price per unit until Sept. 30, 1912.	Price per unit after Oct. 1, 1912.
	Pence.	Pence.
10	2.512	2.475
15	1.754	1.717
20	1.375	1.338
30	0.995	0.958
40	0.807	0.770
50	0.692	0.655
60	0.617	0.580
70 and over.....	0.561	0.525

In addition to the power stations owned by the Victoria Falls Power Co., several others, the property of gold-mining groups, have either been enlarged or come into work during the year, so that, as before remarked, electrical power has become an important item on the Rand. At Randfontein Central the capacity of the electrical installation is now 20,000 kw. The current is generated at 6600 v., 3-phase, 50 cycles, by two 1000-kw., three 2000-kw., and two 6000-kw. sets. The steam is generated by 24 boilers of 17,000 lb. steam capacity per hour, at a pressure of 140 lb. and superheated to 500°F . The boilers are fitted with chain-grate stokers and equipped with economizers, superheaters, and induced-draught plants. The cost at the switch-board is a third of a penny per unit. At the East Rand Proprietary Mines 3-phase current at 3000 v. is generated at a frequency of 25 cycles, and so satisfactory is the power that the works are being augmented up to 19,500 kw. capacity. Here the directors announce that the action of the group in equipping its own station has, as at Randfontein, been justified by the results. At Kleinfontein, too, a power station on similar lines to that at the East Rand Proprietary Mines has during the year been brought into use; in fact, it is intended in the future to couple up those two power stations. At the present time the load factor at the Kleinfontein power station is a very low one, but nevertheless the cost of production is stated to be less than the 40% load factor charge of the Victoria Falls Power Company.

Old Mines at Alamos

In the Alamos district of Sonora, described recently by G. L. Sheldon, there are many old mines, of which the Promontorio is perhaps the best known. At the south end of the district beyond that mine, three-fourths of a mile up the side of the mountain a short distance above the level country, three or four years ago a foreigner made some locations in line with the Promontorio vein and sank a shaft, discovering good ore. There was nothing whatever on the surface to warrant exploration, but he was simply lucky in taking a long chance. A few miles west of there in the vicinity of Arrastras, Clemente Ibarra has several properties. The Promontorio vein is called the 'mother vein' of the country; it is claimed that it can be traced to the Yaqui river, a distance of over a hundred miles. At the north end near the river in recent years a good silver mine has been opened. At Bacauri about half way is a gold belt several miles in length on the same vein. The old Plank mine had a record eighteen to thirty years ago of \$1,200,000 gold, according to the Mint returns at Alamos. It is only 600 ft. deep and is on the contact between granite and andesite. The old mill was on the Cedros river, two miles east of the mine in a short gulch 100 yd. above the river. Five years ago Zeigler Bros. purchased the old tailing, of which there appeared to be only three tons, for \$300, and cyanided it. It proved that a cloud-burst had covered the tailing with wash and they obtained, and treated, 12 tons which netted upward of \$75,000.

Immigrant Gold Mine Workers in Amador County, California

By W. J. LAUCK

It was planned by the recent Federal Immigration Commission, as a part of its extensive investigations on the Pacific Coast, to make a comprehensive study of the labor conditions in metalliferous mines in California. Unfortunately the work of the Commission was suspended before this investigation was completed, but sufficient data had been secured from gold-mining companies in Amador county to afford an interesting insight into the conditions of employment in that locality.

Racial Composition of the Gold-Mine Workers.—Four-fifths of the employees of gold mines in Amador county were found to be of foreign birth, chiefly of races of southern and eastern Europe. The principal races represented were the Dalmatian, North and South Italian, Herzegovinian, Spaniard, and Montenegrin. There were also a considerable number of English miners. About one-tenth of the operating forces were native Americans, and an equal proportion were of native birth, but of fathers who had been born in England, Ireland, or Italy. The most recent immigrant employees were the Spaniards and Montenegrins. About three-fifths of the southern and eastern European mine-workers, however, had been in the United States less than five years.

Characteristics.—Only about two-fifths of the recent immigrant employees, as contrasted with one-half of the native American employees, were married. The significant feature of the situation was, however, that of the immigrant mine-workers who were married, the greater number had left their wives and families in their native countries. Out of a total of 137 married males of foreign birth, 74 reported their wives to be abroad. All races, except the English, reported a majority of the wives living abroad. The English reported 31 of 36 wives living in the United States. The North Italians reported the wives of 25 of their number as living in the United States, but those of 45 as living abroad. As regards ability to use English, of the 331 immigrants of non-English speaking races for whom data were secured, 148, or less than one-half, had learned to speak the language, and only 51 could read, and only 38 both read and write it. Few of the immigrants of any race could read or write English, a fact which is significant as regards the degree of facility in the use of the spoken language. Of the foreign-born employees who had been in the United States five years or longer and who were 21 years of age or over at the time of coming, 93 reported their political status. Of these, 33 had their second naturalization papers, 31 had their first papers, and 29 were still aliens. Most conspicuous among the last named were 18 of 43 North Italians who afforded a sharp contrast with the 23 English, none of whom were aliens.

Racial Displacements.—Originally employees of the mines were Irish, with a few English, Germans, and Italians forming the remainder of the labor force. Race changes during the past twenty-five years have consisted largely in the gradual withdrawal of the Irish, the increase of the English and the Americans, followed in turn by their gradual withdrawal and the replacement of these earlier laborers by recent immigrants from the south and east of Europe. The withdrawal of the Irish, English, and the Americans was due chiefly to the attraction of higher wages which prevailed in newer mining camps in Nevada, Arizona, and Montana, and to the increasing opportunities to secure more remunerative or more congenial employment in the locality of the mines or in the larger cities of the state.

Occupations.—All of the foremen and most of the engineers and mechanics at the mines investigated were either native-born Americans or English. Only one-fourth of the miners or general laborers, on the other hand, were members of these races, the great majority being immigrants from Austro-Hungary and Italy, with a small number from

Spain and Montenegro. Of the immigrant employees, only 1%, consisting entirely of Englishmen, were foremen, and only 3% were engineers or mechanics, while 97% were miners and general laborers. The contrast between the occupations of native Americans and English on the one hand, and the recent immigrant workmen on the other, is due to three causes: (1) Most of the English were experienced miners when they came to the locality, while few of the immigrants from the south and east of Europe had had any experience in the industry; (2) most of the native-born and English engineers and mechanics had learned their trades before seeking employment in the mines; (3) the native Americans and the English were, as a rule, older men who had been employed in the mines for a greater length of time than the south and east Europeans, and were consequently better fitted both by age and local experience than the latter for the more responsible positions in the labor force.

Hours and Earnings.—The hours of labor ranged from 8 to 12 per day. The working week was 6 days for some occupations, 6½ for others, and 7 days for still others. The men employed underground worked only 9 hours per day. The hours of labor above ground, were, as a rule, 8 per day for 7 days in the week for engineers and roastermen, 10 per day for 6 days for blacksmiths, carpenters, and other mechanics, 10 or 12 per day for 7 days for foremen, and 12 per day for 7 days for stamp-mill employees and firemen. Wages ranged from \$2.25 per day for common laborers to \$5 per day for foremen. Miners' helpers were paid \$2.25 per day; carmen, teamsters, lime-pit men, and log-rollers were paid \$2.50; and miners, \$2.50, \$2.75, and \$3. Foremen received from \$3.75 to \$5 per day, mechanics from \$2.50 to \$4, and stationary engineers from \$3 to \$3.50. Among the foreign-born mine-workers, the English were found to the greatest extent in the higher wage groups, but to a considerably less extent than the native Americans. About one-third of this race earned \$3 per day or more, as compared with about one-half of the native-born. After the English, the South Italians showed the highest percentage earning \$3 per day or more. The lowest earnings reported were those of the Dalmatians, Herzegovinians, Montenegrins, and Spaniards, all of whom were employed as miners or general laborers. The North Italians averaged somewhat higher earnings than those of the races last named, but lower earnings than those of the English or South Italians. At work the races employed are purposely mixed in order to secure the benefit of race competition, but at boarding and lodging houses they usually segregate themselves. Socially there are few opportunities for the members of the different races to meet, except those found in the saloons, and the Slavs as a rule patronize saloons conducted by members of their own race. Even the Slavs do not associate freely among themselves. Considerable friction exists between those who are Greek Catholics and those who are Roman Catholics.

THE ELECTRIC STORAGE-BATTERY locomotive which is being tried out in the Berkely mine of the Anaconda company is giving every satisfaction so far, but some time will yet be given over to tests before any decision is reached regarding it. While the storage-battery locomotive is quite expensive, if it is adopted the necessity of wiring will be done away, which in itself is a very large item. The work of installing the trolley system into the mines not yet wired has been stopped.

THERE were 635 mining concessions granted by the Government of India during the year 1910, against 693 in 1909. The decrease was doubtless due to the fact that only six mining leases were taken out for chromite in Baluchistan, as compared with 76 in 1909.

Characteristics of Fuse

*The rates of burning of the various kinds of fuse sold in this country vary from 18 to 40 seconds per foot in open air. However, the miner or shot-firer seldom knows the rate of burning of the different kinds of fuse. It is true that some fuse is marked slow or fast, and is even distinguished by the color of the paper wrapper, but this is not always the case. Without such information, a miner who is accustomed to a certain brand of fuse may use another that burns faster, with the result that a charge may explode prematurely and menace all connected with the work. However, it is believed that the rate approved by the Bureau of Mines—namely, 90 seconds per yard—will meet the various mining conditions in this country.

Careful tests should be made of the rate of burning of fuse whenever there is any doubt as to its soundness. The manufacturers may produce a fuse with a regular rate of burning, but the rate may be changed by bad handling, for instance, by squeezing the fuse so as to disturb the powder train, or by suddenly and roughly opening the coil when it is stiff from cold so as to crack the fuse; or the fuse may be bruised by rubbing against the rough surface rock.

Fuse should be carefully handled and never laid in a damp place before using. In cutting the fuse and in fitting it into place, care must be taken that the powder core does not run out of the fuse, for that might cause a misfire. The fuse should be cut straight across with a sharp knife just before placing the end in the detonator. In a humid atmosphere at least 1 in. should be cut off the fuse before insertion in the detonator. The fuse should be fitted gently and then the detonator should be crimped on the fuse by the proper crimper.

When fuse has been subjected to such conditions as produce acceleration or retardation in its rate of burning it becomes dangerous. Acceleration of the rate of burning increases the liability of a shot going off before the miner has left the face; retardation increases the chance of the flame in the fuse progressing so slowly that the miner will be injured by a delayed shot when he returns to the working face. All conditions that bring about any marked change in the rate of burning of time fuse are dangerous, and from a study of the list of accidents in mines and quarries each year, injury and loss of life are seemingly often brought about by such conditions.

Under ordinary conditions nearly all types of fuse show great uniformity in the rate of burning. Practically all types of fuse examined in connection with the preparation of this report had a total variation in their burning under normal conditions of less than 20%, and all would have been passed under the allowance of "no variation greater than 10% above or 10% below the average rate of burning."

Climatic conditions affect to a considerable extent the rate of burning of the less waterproof types of time fuse. Damp fuse burns more slowly than normal fuse, and fuse that has been wet and thoroughly dried tends to burn at a rather slow rate, and may even cause delayed shots by smoldering for a considerable time. Fuse containing several wrappings of tape saturated with tar or asphalt resist moisture to a considerable extent, and may be used for firing shots under water, provided the fuse is not allowed to remain too long a time in contact with water before the shot is fired.

Coal Deposits of Southern Nigeria

The work of the year of the mineral survey has been concentrated on the further examination of the extensive deposits of coal at Udi, which are found to stretch more than fifty miles to the north of that place. The tests carried out by the Government and the analyses at the Imperial Institute have proved that the surface samples give results

*Abstract from 'Investigation of Fuse and Miners Squibs' by C. P. Hall and S. P. Howell, and 'The Rate of Burning of Fuse' by W. O. Snelling and W. C. Cope; Technical Papers No. 7 and No. 6 of the Bureau of Mines.

equal to two-thirds that of the best Welsh coal. It is reasonable to expect that if the seams are worked the coal that has not been exposed to the weather will be of still better quality. The question of the construction of a railway to connect this coalfield with the river port of Onitsha is under consideration. Sanction for the construction of this line may be given, as the importance of cheap fuel to the two Nigerias, with their combined railway system, already over 800 miles in length, is very great. The price now paid for Welsh coal is, at the coast, 34s. 6d. (\$8.39); at Baro it costs about 52s. (\$12.65), and at Jebba 62s. (\$15.08). It should be easy to deliver Udi coal at Onitsha at 12s. (\$2.92) per ton. Besides the railway requirements, the importance of local coal for river and ocean shipping is very great, and is even of imperial importance. The lignite deposits to the west of the Niger are also very valuable, and those at Okpanam, only ten miles from Abasa, the Niger port opposite Onitsha, vary from 10 to 15 ft. in thickness. The total trade of Southern Nigeria in 1910 exceeded \$55,000,000, whereas it was scarcely over \$20,000,000 in 1900.—From Annual Report of the Governor.

Steam-Shovel Records on the Panama Canal

During the month of December the total amount of material excavated in the central division, according to the *Canal Record*, was 1,361,891 cu. yd., of which 164,252 cu. yd. was classified as earth, and 1,197,639 cu. yd. as rock. Of this quantity, 1,351,082 cu. yd. was removed by steam-shovels, contractors removed 2337 cu. yd. by sluicing, and 8472 cu. yd. by hand.

The high record for the month was made by shovel No. 219, working 25 days in the Culebra district, which excavated 46,322 cu. yd. of rock. The second best record for the month was made by shovel No. 207, working 25 days in the Culebra district, which excavated 45,223 cu. yd. of rock. The best record for a shovel of the 70-ton class was made by shovel No. 126, working 25 days in the Culebra district, which excavated 33,040 cu. yd. of earth. Shovel No. 212, working in the Culebra district, made a high record for one day by excavating 3204 cu. yd. of rock on December 4.

Except where noted, monthly reports are computed by place measurement, while the daily reports are based on ear measurement. The best records for the month and for one day are shown below:

BEST RECORDS FOR THE MONTH

	Earth. (Cu. yd.)	Rock. (Cu. yd.)	Total. (Cu. yd.)	No. of days at work.
Empire District:

203	Culebra	Dec. 27	Rock.....	3135
231	Pedro Miguel	Dec. 20	Rock.....	1900

The total steam-shovel excavation on the re-located line of the Panama railroad amounted to 345,520 cu. yd. The best month's record was made by steam-shovel No. 257, working on the Gatun section, which excavated 58,380 cu. yd. of solid rock. In the 70-ton class the best month's work was made by steam-shovel No. 123, working near Empire, which excavated 19,260 cu. yd. of earth and 12,500 cu. yd. of solid rock, a total of 31,760 cu. yd. The best day's record for shovels with a 5-yd. dipper was made by steam-shovel No. 262, which excavated 3400 cu. yd. of rock

on December 2. The best day's record for shovels with a 3-yd. dipper was made by steam-shovel No. 117, which excavated 2100 cu. yd. of rock on December 11. Month's records are place measurement, and day's records are ear measurement. All material was loaded in 10-yd. Western dump-cars.

BEST RECORDS FOR THE MONTH

		—Cubic Yards by Cross Section.—

Total-number of steam-shovel working days, 260.				
Average output per working day, 1329 cubic yards.				

Ray Central Copper Mining Company

*The property of this company comprises 28 claims, aggregating 420 acres, in the Ray mining district, Pinal county, Arizona. They are divided into four groups, the Globe Isabella, Little Frank, Calumet, and Copper Zone. About one-third of the area is patented land. The Globe Isabella group is in the heart of the great orebody now being mined by the Ray Consolidated, which company, according to latest reports, has developed 80,000,000 tons of ore averaging 2.17%, the greatest proved orebody in the Southwest. The Calumet is the oldest location in the district. High-grade ore has been shipped from its mineralized fault fissures and there are probabilities of disseminated orebodies within its limits. Work is now being done on this group to prove its real value. Three or four drill-holes will be put down before underground exploitation is continued further. The Little Frank group is favorably situated for the finding of the eastern extension of the great Ray orebody on its western claims. The work of proving this will follow that now being done on the Globe Isabella and Calumet. The Copper Zone group was purchased, not only for its mineral possibilities, but because of the millsite which the slopes of Rustler gulch offer. The Ray townsite, on the east end of the Globe Isabella, is a steady source of income to the Ray Central company. The district offers exceptional facilities for cheap mining and low cost production.

The ore occurrence at Ray is identical with that of the Miami-Inspiration belt. Certain portions of the great mass of Pinal schist have been commercially mineralized with disseminated chalcocite ores. The primary mineralization was initiated by the intrusion of masses of diabase and granite-porphry, which, by processes of oxidation and enrichment, have resulted in workable orebodies today. That part of the schist area which is ore-bearing is clearly defined by characteristic indications. Schist, diabase, and granite porphyry carrying chalcocite, will all be mined. The orebody is a tabular mass dipping gently toward the southeast, of variable thickness and undulating contour. The overburden (leached zone) will average about 100 ft. thick. The average grade of ore throughout the camp is about 2.2%. The ores are amenable to simple concentration, and a 70 to 75% extraction should be obtained.

The Ray Central will have the benefit of the results of the Ray Consolidated, Miami, and Inspiration, in the working of these low-grade deposits, both mining and milling. One or the other of the several block-caving systems is proposed, and no serious trouble is anticipated from the water of Mineral creek, which traverses the east end of the Globe Isabella group. The location of the permanent shaft through which

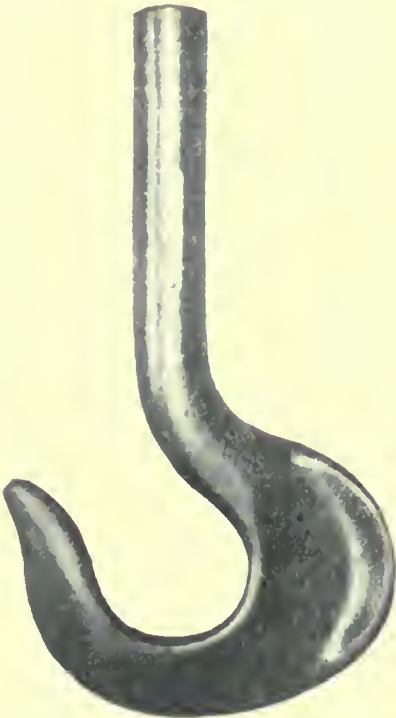

to mine the orebody will be determined on the completion of the fourth level work and drilling under the townsite. The experimental mill-tests already made are satisfactory, 70% of the contained copper being obtainable as concentrate. This will probably be improved upon in actual mill practice. Until the Globe Isabella, Little Frank, and Calumet claims are more fully developed, the erection of even a small capacity plant is inadvisable. Cost of production decreases with tonnage handled up to 5000 tons daily capacity. However, when operating on a 1000 ton per day basis, there is a good margin of profit. With 70% mill extraction and 5% smelting loss, 2.15% ore should yield 28.6 lb. of copper per ton. As an outside figure, assuming only 1000 tons per day treated, the estimated cost of production would amount to a copper cost of 10.38c. per pound. Should the orebodies anticipated on outside claims and on the Globe Isabella justify a daily output of 3000 tons, a production cost of 10.07c. per pound might be attained.

	1000 tons per day.	3000 tons per day.
Mining, per ton.....	\$1.25	\$0.90
Transportation	0.70	0.60
General expense	0.10	0.15
Smelting	0.35	0.35
Refining and marketing.....	0.57	0.57
Total, per ton.....	\$2.97	\$2.57

On this basis the property should produce, working 320 days per year, 27,500,000 lb. of copper per year.

A Safeguarded Hook

The illustration shows a design of safety hook for cranes or other lifting apparatus intended to make it unnecessary for a man to get his hands or fingers into the danger zone

of the hook when adjusting the latter to a chain sling. It will be apparent that the body of the swell of the hook has been carried further than necessary so as to give a leverage and grip at the back above the reach of the nip of the chain. The hook can be much better guided in any direction also from the back, and both convenience and safety are secured.—*Jour. Indust. Safety.*

THE large deposits of saltpeter found on Cabinet land, near the village of Doroninskaja in the Herchinsk mining district of Siberia, are now being examined by the chief chemist of the district and five English chemists, the latter representing an English syndicate whose intention it is to establish large works for the manufacture of soda.

*Excerpt from a report by W. H. Weed and F. H. Probert.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliement. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Laboratory Cyanide Tests

The Editor:

Sir—The description of apparatus for use in making cyanide tests, published in your issue of December 30, calls for comment in spite of the fact that the author, George A. James, states that the duplication of the conditions obtaining in actual practice was aimed at.

In the leaching of gold-silver and, more especially, silver-gold ores the ratio of depth of sand to satisfactory extraction is an important question. The dimensions of Mr. James' apparatus limit the practical application from any results obtained to a depth of sand of about 3 ft. To carry out experimental work on 3 ft., or less, and to expect similar extractions with 10, 15, or even 20 ft., is a common mistake. In many instances the residual content varies directly with the depth leached, and exceptional cases have been known where a residue sample taken from the bottom of a leaching vat, after prolonged treatment, has been found to contain a higher metal content than did the original charge. My own opinion is that the great majority of estimations made to determine possible extraction by leaching are of little value on account of the absurdly small amounts of sand taken for treatment in the preliminary experimental work, and the production of data obtained from investigations on a depth of material too shallow to demonstrate the chemical changes in the solution, and resultant effects on extraction, occurring in an ordinary leaching vat.

The second point needing comment is that Mr. James' arrangement, in avoiding "the contamination of the solution by the laboratory gases", prevents its frequent aeration by natural means. Where reducing action is evident, an advantage is gained by the periodic draining of the charge, and the intermittent application of solution washes.

The third point to which I would draw attention is that Mr. James' apparatus possesses no contrivance by which the effluent can be shut off, or by which the rate of leaching can be controlled. The preliminary 'soaking' of the ore in strong solution necessitates some valve arrangement, and if Mr. James' method of uncontrolled gravity leaching were adopted in practice with a coarse clean sand the pumping expense would be prohibitive. The determination of *maximum* percolation rate is of secondary importance to the determination of *efficient* percolation rate, since the rushing of solution through a bed of sand results in the handling of, and precipitation from, large quantities of low-grade solution, the production of base precipitate and its attendant expense and trouble.

I am indebted to my early laboratory training in such work and I have never departed from the use of ordinary 4-in. piping in the experimental determination of cyanide extraction by leaching. The pipes are fitted with bored flanges, at one end for suspension and at the other for the filter bottom. The latter is kept in place by a third flange with insertion joint, and fitted with a plug tapped for a small leaching-control pipe, an arrangement incidentally providing for the upward charging of strong solution. The pipes should be cut or compounded of a length equal to the height of the vat it is proposed to use in practice; or, if the dimensions of the latter have not been decided upon, experiments should be made with various lengths. In all cases, and at the conclusion of treatment, bored samples should be taken at the top, and also at the bottom of the pipe, and the assay results compared. Equality of residual content would indicate the possibility of treating larger bulks of ore by an increase in the height of percolation. A higher residue at the bottom than at

the top would indicate the necessity of reducing the leaching depth, or of resorting to double treatment. In most cases the latter method is preferable to single treatment. Head and tail samples should be taken after the charge has been thoroughly mixed, before and after treatment.

While regretting the destructive nature of the criticism on the article, I would like to add my agreement in the matter mentioned by Mr. James as to the importance of the re-use of barren, and not freshly prepared solution, in experimental work; and I take this opportunity of adding that cyanide consumption estimations should not be calculated experimentally in the manner advocated in treatises on cyaniding, but should be based on methods involving the titration for total cyanide percentage in the solution before treatment, and after treatment *and precipitation of metals*; the experiment should be made, not with distilled water and pure potassium cyanide, but with barren solution containing the normal amount of the double cyanide of zinc and potassium, and any other salts induced by the continued use of the solution in the treatment of similar ore; and the actual amount of commercial cyanide, of analyzed KCN content, needed to re-standardize the solution should serve as a check on the titration difference.

London, January 15.

A. W. ALLEN.

How Can Alaska Be Developed?

The Editor:

Sir—I have resided continuously in Alaska during the past eleven years. I have sought during that time all available information concerning the country and have labored to keep posted on the opinions of all who have expressed their views on Alaskan matters. So far as I am aware, not a single article appearing in the public press has been written favoring so-called 'conservation' as applied to Alaska by anyone personally familiar with the paramount facts concerning the country; a knowledge of which is essential to the formation of a reliable opinion as to its real needs. The country at large has based its opinion as to the course the Government should pursue in Alaska upon information much of which is misleading. That all honest American citizens desire to see the vast mineral resources of the 600,000 square miles comprising Alaska developed as rapidly as possible, may be safely asserted. The vital question is, how is this to be accomplished? It is manifest that while there can be only one best way, there are numerous courses which must lead to partial or complete failure. A glance at a few of the conditions prevailing in Alaska will give some idea of the vast difference there is between it and all other parts of the country, and which make impossible development along the industrial lines which have become standardized in other districts. In order to understand the local situation it is necessary to note the following facts:

1. That most of the mineral wealth of Alaska is wrapped in ice and snow, and that the remainder is covered with a blanket of thick moss, impenetrable to the human eye and forming a severe obstruction to travel.
2. That the length of days and nights is unfavorable to the performance of the usual maximum day's work.
3. That in the absence of good wagon-roads and railroads, the transportation of food and other supplies must be conducted in the winter when the days are shortest and the cold most intense.
4. That cost of transportation to the interior varies from about \$100 to \$1000 per ton, depending on distance from supply points.
5. That supplies even at supply points necessarily are high in cost.
6. That outdoor work, when the thermometer runs down to from 50° to 70°F. below zero, which often occurs every winter and for long periods, is unavoidably difficult as well as costly.
7. That large quantities of fuel at high cost are necessary to any industrial undertaking.
8. That all prospect and mine work must be done in frozen ground, and is done by thawing.

9. That the wagon-roads and railroads of today are of too limited mileage to materially assist in developing so large an area as comprises all of Alaska, and that it will require many decades to construct a sufficient mileage to meet even the most pressing needs of even the one-fifth of Alaska that has been geologically surveyed by the Government.

10. That, according to Government geological reports, each of the ten districts comprising the already surveyed one-fifth of Alaska contains large areas of coal or lignite suitable for local use. None of the coals, except those near tidewater and of high fuel value, will ever stand the cost of ocean shipment. The coals, scattered far and wide over the interior, are absolutely essential to the development of the mines of the interior and the local treatment of ores, and the local operation of allied industries, including domestic consumption.

The foregoing are only a few of the controlling facts that must be reckoned with in determining the best course to pursue by the Government in its difficult task of developing the vast mineral and agricultural resources of Alaska. It is no boy's job—nor yet is it the task of any one or all of the theorists of the country. In solving the problem 'What shall the country do for Alaska?' conditions must be met for which, as a whole, the history of no nation furnishes any exact parallel. Only the application of the hardest of hard common sense will avail. The United States has surpassed every other nation known to history in rapid development, and this has been done by and through a wise and liberal land policy. It is mainly through this policy that patriotic successful citizens have been made of the vast hordes of foreign immigrants coming each year to our shores from the lands of poverty and oppression. This has been accomplished by attaching the masses to the soil. The progressive citizen is primarily the product of the land he owns. Landlordism is a failure and always has been, and it may be safely asserted always will be. Even the United States Government is not powerful enough to develop Alaska through a floating tenantry. Indeed, this was tried on the public copper and lead lands of our country from 1807 to 1847—forty years—and proved a dismal failure. Notwithstanding all history condemns the leasing system as a complete failure, there have arisen men, said to stand high in public favor, who are strenuously urging a leasing system for all the public mineral domain of Alaska. Why not include agricultural lands also? The reasons for leasing the one are just the same as for leasing the other.

Some of the objections to a leasing system are:

1. The American citizen will not lease. That was the trouble during all the 40 years leasing was tried in the copper and lead districts. The system is distinctly un-American.

2. Any leasing system will effectually eliminate the prospector and pioneer—especially in Alaska, where the hardships are vastly greater than anywhere else. The prospectors and pioneers as a class are the bravest, most industrious, most persistent, and most independent thinking men on earth. They never work for wages, except to secure more means with which to prospect until they find some natural resource to which they can acquire title. They are the only men who will or can open Alaska sufficiently to induce capital to perform its necessary part in developing the country. This is an old, old story to him who has in the least informed himself as to how the deserts and mountains of our country have been conquered and made to yield up their treasures. The history of these men is the history of the development of our entire country. Without them our history would have been like the play of Hamlet with Hamlet left out.

Hard common-sense says, "follow methods which you have always found successful, and do not try an experiment which you have—as all others have—found to be a failure." What Alaska needs to develop it is such a liberal land policy as will induce the prospector and pioneer to find valuable mineral deposits which he can locate, and a liberal offer to farmers to enter and cultivate the

agricultural lands in the valleys so as to furnish food for consumption by miners among the adjacent hills. The development of mineral and agricultural lands should go hand in hand, and will do so with proper Government inducements. A leasing system of any sort is condemned by 90% of the residents of Alaska, and it is safe to predict that, under any leasing system, Alaska will shortly be almost entirely depopulated. If the prospector and miner cannot take from the public land timber and coal sufficient to enable him to find and open his mine without subjecting himself to prosecution, he will abandon prospecting and mining in Alaska.

JULIUS THOMPSON.

Katalla, Alaska, January 5.

The Editor:

Sir—It is always a pleasure to read thoughtful discussion, however much the views expressed may differ from your own. With much that Mr. Thompson says I heartily agree. The natural difficulties in the way of development in Alaska are of a sort by no means properly appreciated. It needs but a day's scramble through the 'devil's club' and moss that cover so much of Alaska's hillsides, to bring home the fact that the practical work of prospecting such a country is difficult in the extreme. It calls for a high order of courage as well as of intelligence, both of which have been admirably displayed by Alaskan pioneers. That many of the wrecks of humanity having little but brute courage have floated into the north need not detract from appreciation of the heavy demands made by Alaska upon real prospectors. It is one thing to get a *klooch* and a canoe and camp along a salmon stream till increasing snow makes it necessary to break samples from some well known outcrop, in order to have a suitable basis for a report to the grubstake partner. It is quite a different thing to really explore Alaska and to prove veins and placers. The men who do this work are deserving of rich reward, but I am unable to see that the real economic service that such men perform necessarily requires as its price a return to free-for-all conditions where with a good axe and a sufficiently long list of names, one man was allowed to monopolize a stream or a whole country-side. Neither do I agree that Americans will not lease. They will and do, as may be learned by a little inquiry in any mining district here or abroad in which leasing affords the basis of title. Furthermore, when leasing direct from the United States was in vogue in the lead regions of the Mississippi Valley, Americans took the leases, as is proved by the documents in the case. Leasing was done away with there for the reason that the people wanted something for nothing and were able by fraud and intimidation to wear out the patience of the Government. When internal revenue taxes on whisky were first established, armed insurrection ensued, and for nearly ten years there was actual fighting. In that case, however, the Government stood its ground. Would Mr. Thompson contend that it would have been better to abandon the then 'un-American' internal revenue taxes? At the times these two difficulties arose, conditions were not dissimilar. They seem so now, merely because the Government acted differently in the two cases. I am not among those who believe that a large national revenue can or should be raised by leasing mineral ground, but I do not see that a leasing system for mines is *a priori* either impossible or un-American. The advisability of introducing such a system is a matter to be settled on the merits of each case and with an eye to the particular form of lease that it is proposed to use. Incidentally, and for many years to come at least, I believe that revenue from the mines of Alaska should be employed in Alaska for building roads and for other public uses. More will be needed for such purposes than is likely to result from any reasonable scale of either royalties or taxes. Alaska does not need landgrabbers as much as it needs mines, and I believe a proper leasing system will discourage the one and encourage the development of the other.

San Francisco, January 29.

H. FOSTER BAIN.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

GROUND phonolite as a potash fertilizer is causing much discussion in Germany, where active efforts are being made to introduce it into the trade. Authorities claim, however, that it is of little value, containing only 8 to 10% of not easily available potash.

TO disconnect or remove a safety device which has been attached to a machine under the direction of the safety inspector of the state is, according to the law of New York, a misdemeanor, and the fine imposed for an infraction of the law acts as a strong deterrent to carelessness and leads to a decreased number of accidents.

THE appearance of a raw clay is no criterion whatever as to the color of the burned product. The colors of clays vary widely, from the white of kaolin to the dark red, or black, of the red burning clays. The main coloring constituent of clays is iron oxide, and according to the amount present it gives colors ranging from buff to red.

SATURATION is important but difficult to determine in any oilfield. Some lands yield 2000 to 3000 bbl. per acre and others as much as 100,000 bbl. At times, as one operator phrases it, "more oil comes out of a well than there is space in the rock below." Such anomalies are probably to be explained on the basis of fractures tributary to the well.

WHERE the gravel from drift mines has to be brought to the surface through vertical or inclined shafts, the kind of motive power to be employed for the purpose depends on the circumstances. If there is but little material, a hand windlass may suffice; with more, then a horse whim, steam hoist, or water power may be used. Gasoline engines will often serve every purpose, and a small distillate engine will give excellent service.

IN assaying silver bullion containing tin, if the ordinary wet method be employed, much trouble is experienced, varying with the amount of tin present. Even with a percentage as low as 0.05, the end-point is masked by a persistent turbidity, while with amounts ranging from 0.5% upward, the determination of the exact end-point is impossible, owing to the finely divided or colloidal metastannic acid resisting all efforts to cause it to settle, or to give a clear supernatant liquid.

TELLURIUM can be detected in ores by a method recently described by G. T. Holloway, who suggests a method of isolating tellurium from ore for testing purposes, by concentrating it with the gold and silver in a lead button obtained by the ordinary fire assay, it being possible to treat as much as 50 to 60 gm. of ore in this way. The lead button is then dissolved in nitric acid, diluted, and the tellurium precipitated by means of lead foil, the deposit thus obtained being cleared and tested by concentrated sulphuric acid. If tellurium is present a deep violet color is produced that disappears on further heating. Manganese peroxide, when present, sometimes interferes with this test.

VALUATION of oil wells is difficult and uncertain. In the Appalachian fields, where conditions are better known than is usual elsewhere, it is customary to appraise ground on the basis of daily production, after the property has been operated successfully and the wells have settled down to regular output. On this basis the average sale price of producing lands varies between \$800 and \$1000 per barrel of daily production. This price covers all the usual field equipment. At these prices the purchaser expects to recover his capital and from 100 to 200% within a period of 5 to 10 years, and often does better. The average price, at the well,

of Pennsylvania oil is about \$1.30 per barrel. To apply the same rule in other fields, if it be thought wise, allowance must be made for the difference in price of oil. In Illinois, during the first three years of oil development, producing properties changed hands on a basis that provided for return of capital in 18 months from known production and at current rates.

ADMITTING compressed air into the gas-engine cylinder at the end of the exhaust stroke is proposed in a recent issue of the *Zeitschrift des Vereines Deutscher Ingenieure*. It is recognized that the residual burned gases remaining in the cylinder and mixed with the new charge dilutes the fresh mixture, impoverishes it, and generally interferes with the ignition of the charge, unduly elevates the initial temperature, predisposes the motor to premature explosion, and affects the efficiency of operation. It was there shown by means of diagrams and figures of a number of tests how the efficiency was increased as the result of the adoption of the valve which admits the air under pressure at the end of the exhaust stroke.

LIFE of timber inside a mine varies with conditions of temperature and moisture, as the fungus which destroys timber must have a definite amount of air and water, food and heat, in order to exist. If mine conditions were such that the timber could be always kept wet or always dry, it would never decay. Poorly ventilated gangways and air passages with a fair degree of moisture and a fairly high temperature, such as are especially common in the anthracite region of America, are favorable to fungus growth and hence to rapid decay. Right preservative treatment may reduce disease and decay in mine timbers to a minimum, but it is probably impossible to exterminate the disease and wholly prevent the decay. The enormous quantities of timber consumed by the mines, and the necessity for the replacement of the entire equipment inside the workings of an anthracite mine in twelve to eighteen months, emphasizes the unsuitability of wood for this purpose and the economic waste involved in its use.

FOR ASSAY of gold and silver-bearing cyanide solutions, take, in the case of ordinary mill solutions 10, and in that of barren mill solutions 20 assay tons. Remember that 1 assay ton equals 29,166 grams, or 29,166 c.e., so that 10 A.T. is equivalent to 291.66 c.e. Transfer the necessary amount of solution to a large beaker, add a bunch of zinc shavings about the size of a hen's egg. Warm the solution gently for 15 minutes. Gold and silver will immediately commence to precipitate on the zinc. At the end of the above period, add 60 c.e. of a saturated solution of commercial lead acetate in water. The reaction immediately starts between the lead acetate and the zinc shavings, producing metallic lead and zinc acetate. At first the solution will be milky, but in 30 to 40 minutes it will clear, leaving metallic lead in spongy form, and some undissolved zinc shavings. Keep the solution boiling hot during this reaction. Now, add 30 c.e. hydrochloric acid, which rapidly dissolves the remaining zinc. The lead will settle in a spongy mass at the bottom of the beaker, decant carefully, washing several times with water. Collect the lead first with glass rod and finally with the fingers, forming it into a cube for subsequent cupellation. After a little practice in washing, the operator becomes so proficient that there is practically no chance of losing metallic lead. The lead button is dried, placed in a cupel and cupelled. The resulting bead is weighed and parted, the weight of gold and silver in milligrams representing ounces in 10 (or 20) tons of cyanide solution, from which the value per ton is readily figured. The addition of zinc to the cyanide solution causes a precipitation of gold and silver on the zinc in the usual manner. Lead acetate reacts upon the zinc, forming soluble zinc acetate and metallic lead. The metallic lead mechanically collects the gold and silver. The addition of hydrochloric acid dissolves the remaining zinc without interfering with the lead, gold, and silver. Decantation removes soluble salts. Cupellation removes the lead, leaving gold and silver.

TORONTO, CANADA

HOLLINGER REPORT ANALYZED.—DOME ADOPTS EIGHT-HOUR DAY FOR UNDERGROUND WORKERS.—COBALT BULLION PRODUCTION IN 1911.—GENERAL NOTES.

The long-anticipated report of Percy A. Robbins, manager of the Hollinger, dealing exhaustively with the physical condition of the property, which made its appearance toward the close of January, proved a disappointment so far as its effect on the stock market was concerned. It failed to arrest for more than a day or two the downward tendency in Porcupine stock; the advance which at first resulted being followed by a rush of profit-taking and a further decline, stimulated, no doubt, by the criticism of experts who disagreed with Mr. Robbins' conclusions. The report is a lengthy and comprehensive document going extensively into details, but the sum and substance of it is that, in the aggregate, the orebodies so far discovered, making conservative allowances for the persistence of the veins below present workings, have an estimated tonnage of 462,000 tons with a gold content of about \$10,230,000, which during the next four or five years would yield profits

HOLLINGER NO. 1 SHAFT AND TEST MILL.

amounting to \$7,500,000. The estimate is based on the results of extensive sampling, for which about 3000 samples, both from the surface and the underground workings, were taken. The greatest depth allowed for in the estimate of tonnage is 300 ft. (being in most cases 100 ft. below the depth actually reached), and the report goes on to say that every 100 ft. of depth below the 300-ft. level on No. 1 vein will add \$2,100,000 to the profit, adding that experience in stockwork formations in other parts of the world has shown that veins continue to depths of 1000 to 2000 ft., so that there can be no doubt as to the conservatism of the estimated depths of the Hollinger veins. This is just the point, as being too optimistic, upon which the critics of the report are disposed to take issue. The cost of the Hollinger mill when completed will be about \$275,000, and it is expected to be in operation some time in April. It will have a crushing capacity of about 300 tons per day, with provisions for such increase as may be found necessary, while the cyanide plant is being constructed for a capacity of 500 tons per day. The official announcement is made that the details are being arranged for a merger embracing the Hollinger, the Miller-Middleton, and the Dixon-Gillies properties, amounting in all to 15 claims, and that Hollinger shareholders will participate in the new issue.

At the Dome an adit is being run from a point near the mill to No. 1 drift at the depth of 45 ft., as a means of taking out the ore from that level, while leaving shafts No. 1 and 8 free for development work. A double track will be put down, on which cars will convey the ore to the mill. By means of a hoisting drum, trains of six cars can be hauled to the surface, and it will be possible to take out 1000 tons per shift through the adit. The eight-hour system has been adopted for underground workers, the surface men working nine hours per day. Charles M.

Henrotin, formerly manager of the Kimberley diamond mine, South Africa, has been placed in charge of the underground work. The Apex has been closed down until spring, when it will be possible to obtain a sufficient supply of water, as the management does not consider it advisable to install a large pump in order to keep the plant running. The West Dome has considerably limited its operations and laid off most of the surface men. The Little Pet is in good ore at the 100-ft. level and is installing a Jencks mill with five stamps of a weight of 1250 lb. each. The McIntyre has cut a vein of quartz carrying sulphide and native gold at the 200-ft. level. At the Dome Lake, south of the West Dome, two shafts are going down on a large sulphide vein, which has been traced for 1300 ft. A 6-drill compressor will be installed. The Rea is sinking the shaft from the 300 to the 400-ft. level, where the next station will be cut. The work is being done with small hammer-drills, which have been found more economical than the reciprocating drills at first used. The McEnany has cut an orebody 5 ft. wide at the 173-ft. level, which yields assay returns between \$20 and \$30 per ton. On the North Dome a 2-ft. vein showing free gold has been found in No. 2 shaft, at a depth of 60 feet.

The bullion production of Cobalt during 1911 amounted to 3,772,920 oz., valued at \$2,012,428, of which the Nipissing contributed 2,352,758 oz., worth \$1,268,495. The output for 1910, which was the first year in which Cobalt shipped bullion, was 945,702 oz., valued at \$501,815. The subsidiary properties of La Rose Consolidated are showing up well. Good ore is found in the winze put down from the 60-ft. level of No. 9 vein of the Lawson, the vein averaging 7 in. wide of 2000-oz. ore for 45 ft. At the Princess the main stope is 225 ft. long and full of ore from the second level to the surface. In a raise from the second level on No. 6 vein, 2 in. of 2000-oz. ore has been discovered, and a find of high-grade ore has been made in a winze below the same level. At the Provincial, now under the management of John Riddington, a vein, 1½-in. wide, of rich ore with the wall-rock carrying silver for 2 ft. on each side, has been found in the conglomerate 60 ft. from the shaft on the 300-ft. level. The Beaver has put shaft No. 1 down to 550 ft. and is going deeper. A station is being cut and a level run at the 530-ft. level. The Buffalo mill treated 4088 tons of ore during December, recovering 144,440 oz. of silver, or 87.70% of the silver disclosed by assays before milling. The annual report of the Wettlaufer for 1911 showed a profit of \$313,390. The ore reserves were estimated at 1,003,000 oz. The Wettlaufer has taken an option on the Keeley mine, a hitherto unfortunate enterprise in South Lorrain which was one of the assets of the insolvent Farmer's Bank, and agreed to spend \$15,000 per month for a year in development work. The Mond Nickel Co. has acquired 2400 acres of land at Coniston in the Sudbury district as a site for a large smelter, construction of which will be started in the spring.

ST. PETERSBURG, RUSSIA

RUSSIA'S COPPER PRODUCTION SHOWS INCREASE.—MAY USE ELECTRICITY IN PRODUCTION OF FERRO-MANGANESE.

The copper production of Russia in the first nine months of last year is reported to have amounted to 1,121,257 poods, against 1,031,456 poods in the corresponding period of 1910—increase 8.4%. By districts the yield in copper was: Urals, 587,000 poods; Caucasus, 328,000 poods; Siberia, 165,000 poods. The waste smelted in various chemical works amounted to 41,000 poods. The Urals with its leading position includes the Kyshtim works, which produced 162,000 poods of copper this year, against 85,000 poods last year; always for the first nine months.

The congress of manganese producers at Tiflis near the Black Sea has appointed a committee to enquire into the possibility of using electricity for the production of ferro-manganese. The Sharopan manganese industry, near Tiflis, has been in a critical state for a long time now, and it has been urged over and over again that the coal to be found in the neighborhood should be used to produce ferro-

manganese. Probably the coal available has not proved to be of sufficiently good quality, and hence the appeal to electricity.

LONDON

STEEL WORKS FOR VEREENIGING, TRANSVAAL.—MALAY WOLFRAM PROPERTY TO BE DEVELOPED.—SOUTH AFRICAN COMPANIES PROFIT BY EAST RAND PROPRIETARY AFFAIR.

For several years past there has been much discussion as to the possibility of establishing the manufacture of steel in South Africa. In the issue of *The Mining Magazine* for January 1910 a review of the situation was given by one who was in thorough touch with the plan. He, however, withdrew on account of certain restrictions imposed by the Government. Just recently the scheme has been taken up by the firm of Lewis & Marks, who have, with the assistance of Frederick Siemens, and of the people with Sheffield experience, evolved a plan for establishing a steel works at Vereeniging. This town is on the main line of railway from Cape Town, and is situated on the north side of the Vaal river, thirty miles south of Johannesburg. It is in the centre of the coalfield belonging to the Vereeniging Estates, Ltd., controlled by Lewis & Marks, and a great electric power station is being constructed there by the Victoria Falls & Transvaal Power Co., Ltd. The plan is to erect a steel works at a cost of £65,000, with a calculated output of 10,000 tons per year, and at first to use only the scrap metal, which is purchasable in abundance in South Africa. A specialty will be made of drill-steel and tool-steel, mine rails, fencing standards, and such castings and forgings as may be in request. The Government has agreed to foster the industry by purchasing material and giving preferential railway rates. H. H. Wright, of Johannesburg, is one of the directors, and he has transferred to the company his rights in connection with the iron-ore deposits at Magnet Heights, in the Lydenburg district of the Transvaal, and the Government has stipulated that, at the end of three years, the company is to commence experiments in connection with the smelting of native ores. It will be remembered that F. W. Harbord has recently reported on the iron-ore resources of South Africa.

At the present time no metallic tungsten is produced in England, though many firms have tried their hand. A small amount of wolfram is produced in Cornwall, but it goes to Germany for treatment, as does all that is mined elsewhere in the eastern hemisphere. Wolfram is a widely-distributed mineral, but it seldom occurs in large enough quantities to make its exploitation profitable. I have recently referred in this column to new wolfram ventures in Queensland and New South Wales. Another in the East is now being introduced to the notice of London investors. This is in the state of Trengganu, a state in the Malay Peninsula which came under British protection as recently as 1910. The property is situated some distance up the Dungun river and is reached in 38 hours by steamer from Singapore. The ore is found in a quartz lode that traverses slate, and the average content is 8% wolfram. For some years the Chinese have been working the lode, and making a fair profit. More recently, E. H. Sharpe, of the firm of Sharpe, Ross & Co., acquired the mining rights, and, through a company specially formed for the purpose at Singapore, called the Dungun River Concessions Syndicate, has done a good deal of development work. The Syndicate asked Osborne & Chappel, of Ipoh, Perak, a firm well known in the East in connection with tin and wolfram, to make an examination. Their report is generally favorable, and they recommend systematic development on certain lines. They wisely urge that a concentration plant should not be provided just yet. For the purpose of raising the capital for development work, an English company has been formed, called the Dungun River (Trengganu) Wolfram Development Syndicate, with a capital of £40,000, of which £20,000 in shares goes to the old syndicate, and 20,000 £1 shares are being offered for public subscription. Of the latter, 16,000 have been underwritten by Sharpe, Ross & Co. This shows

that those who know most about the venture are ready to stake their money. Reginald Pawle and Henry Brelich, two London engineers well acquainted with the East, are acting as consulting engineers to the new company. Sir E. W. Birch is a director; as he is chairman of the Eastern Smelting Co. of Penang, which recently came under British ownership, it looks as if there were some intention of treating the ore locally. There appears to be a fair prospect of wolfram properties becoming profitable, for its use in the manufacture of armor-plate and tool-steel seems likely to expand with the supply of the raw material. Nearly 1000 tons of metallic tungsten is used per year in Sheffield, where tool-steel containing 20% of the metal is produced. The steel-makers there prefer the oxide or the metallic powder, and object to the more recent product, ferro-tungsten, made in the electric furnace on the Continent, as it contains too much carbon. The amount used in the manufacture of filaments of electric lamps cannot be great in the aggregate, and would not be sufficient to keep the mining industry going. Like many other things, the use of tungsten as an alloy for tool-steel was first publicly demonstrated in America, and the exhibit of the Bethlehem Steel Co. at the Paris Exhibition of 1900 served to attract European makers. Creusot in France, and Krupp in Germany followed by using it in armor-plate manufacture. I believe that the latter firm contracts for the supply of wolfram from the United States. Probably the yearly production of wolfram concentrate throughout the world is about 6000 tons, containing 2500 tons metal.

I have referred several times to the case of the East Rand Proprietary, and to the disastrous consequences of keeping secret the difficulty experienced in maintaining the yield of gold at the level prognosticated two years ago by Sir George Farrar and his fellow-directors. Though naturally the incident has done some damage to the prestige of the Rand and to the market for Rand shares, it has not been without its uses as a tonic to the other 'houses.' For instance, it has now been agreed by the other houses that shareholders shall in the future be allowed to see the yearly reports before sending in their proxies, and these reports are to be circulated for quite two months before the meetings are held. This is the nearest approach that is possible, according to the company law of the Union of South Africa, toward a full recognition of shareholders' rights. It is urged that Rand gold mining companies ought to hold their meetings of shareholders in London, and theoretically this would be the right thing. But unfortunately directors have another duty toward shareholders, that is to say, they have to dodge the assessor of taxes. If a Rand gold mining company held its annual meeting in London, it would be reckoned a London company and would be made to pay English income tax as well as the Transvaal tax on profits. A year or two ago the highest courts in England decided that the De Beers Diamond Mining Co. had to pay income tax in England, though it was registered under Cape Colony law and was conducting business in that province and not in England. The French and German shareholders are hit hard by this duplication of taxes, for it is obvious that a Continental investor in South African mines ought not to pay the tax on incomes that is exacted for the purpose of English public revenue.

BUTTE, MONTANA

NORTH BUTTE DISCOVERIES.—B. B. THAYER LIKES COPPER SITUATION.—TUOLUMNE DIVIDENDS.

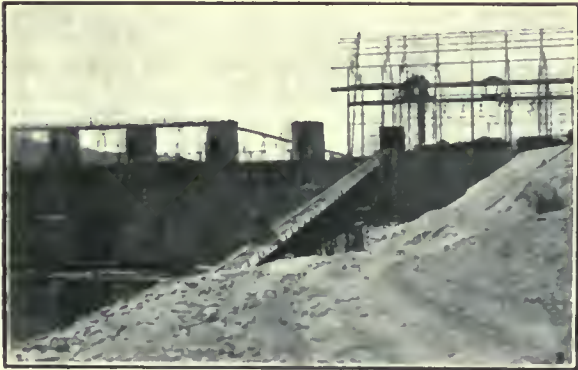

Between the two veins, one on the 1600-ft. level and the other on the 1800-ft. level, and the vein opened in the Snowball claim, the North Butte mine is in promising condition. On the 2200-ft. level of the Snowball the vein is now about 22 ft. wide, and the ore averages about 10% copper. Much of this ore is now going to the Washoe smelter. The ore on the 1600 and 1800-ft. levels is said to be running close to 12%. While it is denied that the Edith May vein has been cut on the 2800-ft. level, men working in the mine insist that it has been, and that the ore expected was not found.

The Tuolumne company is expected to resume dividends again about next July. They were stopped last year in consequence of the heavy expense incurred in building a railroad spur from the mine to the Butte, Anaconda & Pacific tracks, and on account of the expenditure to be met in the erection of a new surface plant. The railroad spur has been in operation since last fall, and the new surface plant is completed, and all the payments have been promptly met without crippling the treasury. Mr. Hickey, the president, is an ultra-conservative man, and while there is no doubt all this extra expense could have been cared for and the dividends paid at the same time, he insisted that they should be passed for a time, so as not to deplete the treasury. When they are resumed they will be 15 cents, the same as before. The contract with the Anaconda company for the treatment of ore at the Washoe smelter expired on the first of the month, and while it has not yet been renewed, the favorable terms secured leaves no doubt but that it will be in the course of a few weeks. In the meantime, the ore is going to the smelter as usual and under the terms of the contract. The company will start about the first of next month to sink the shaft from the 1800-ft. level to a depth of 2000 feet.

GLOBE, ARIZONA

WORK AT THE MIAMI.—PROGRESS AT OLD DOMINION.—
NEWS OF THE DISTRICT.

The starting of the sixth unit of the Miami concentrator is still delayed by the non-arrival of the three 8-ft. Hardinge pebble-mills which will follow the rolls in that unit. The mill is now treating over 2500 tons per day with five units working, the recovery being from 72 to 73%. Development on the 750-ft. level is being pushed forward. Where the cross-cut from the main shaft intersected the

MIAMI MILL WHILE UNDER CONSTRUCTION.

orebody, the ore is reported to assay 4.76% copper. One churn-drill is at work near the old No. 3 shaft and has not yet passed through the capping. Over 750 men are employed, of whom 440 work underground.

The output of the Old Dominion smelter for January was 2,026,000 lb. of fine copper. The company is planning to put in skips for hoisting the ore, and will include a remodeling of the crushing plant and sampling mill. Some changes will be made in the concentrator which will increase its capacity to 700 tons per day. At the smelter a separate dust-chamber will be constructed for the converters, and a machine installed for cheap handling of converter slag, all of which will be re-smelted. The Gray shaft of the United Globe is shut down for re-timbering, and the work of concreting the Kingdon shaft is progressing satisfactorily. The company now has about 900 men in its employ. At the annual meeting of the shareholders of the Copper Reef Consolidated Mines Co., held in Globe February 5, the board of directors was reelected with the exception of J. W. Gillingham, who was succeeded by W. A. Griffith of Pittsburg. M. J. Kennedy, of Scottdale, Pennsylvania, was reelected president at a meeting of the directors, and W. A. Griffith was made secretary. Charles

Saxman was elected to the position of manager, succeeding John W. Gillingham, whose contract expires March 1. The property consists of 80 claims about 12 miles south of San Carlos, reported to have favorable surface showings of copper. Excavation is completed for the foundation of the new hoist at No. 2 shaft of the Live Oak mine, and preparations are being made to enlarge the shaft to three compartments. An Ingersoll-Rand compressor, capacity 1300 cu. ft. of free air per minute, has been ordered. The eastern end of the orebody is being developed from No. 1 shaft. Hole No. 2 of the Southwestern Miami Development Co. is down over 600 ft. and is still in the capping. Ore is expected at 900 ft. The churn-drill hole on the Barney group is now over 600 ft. deep. P. S. Tate and Abe Lyle are leasing on the 100-ft. level of the Black Warrior mine. The Warrior Copper Co. has sold its teams and store supplies. The Copper Hill shaft of the Arizona Commercial is being re-timbered preparatory to starting development work after the bonds of the old company have been foreclosed and the new company has taken possession. The South Live Oak company has been formed to develop the Schultze group of claims lying a mile southwest of the Live Oak.

WASHINGTON, D. C.

NEW ACT FOR BUREAU OF MINES.—SPECIAL FEATURES APPROVED BY SECRETARY OF INTERIOR.—FACILITATION OF WORK OF FEDERAL BUREAUS.

The Committee on Mines and Mining of the House of Representatives have submitted their report upon House bill 17260, amending the act establishing a Bureau of Mines in the Interior Department, and the bill in its final amended form is as follows:

"Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, That the Act to establish in the Department of the Interior a Bureau of Mines, approved, May sixteenth, nineteen hundred and ten, be, and the same is hereby, amended to read as follows:

"That there is hereby established in the Department of the Interior a bureau of mining, metallurgy, and mineral technology, to be designated the United States Bureau of Mines, and there shall be a director of said bureau, who shall be thoroughly equipped for the duties of said office by technical education and experience and who shall be appointed by the President, by and with the advice and consent of the Senate, and who shall receive a salary of six thousand dollars per annum; and there shall also be in the said bureau such experts and other employees, to be appointed by the Secretary of the Interior, as may be required to carry out the purposes of this Act in accordance with the appropriations made from time to time by Congress for such purposes.

"Sec. 2. That it shall be the province and duty of the Bureau of Mines, subject to the direction of the Secretary of the Interior, to conduct inquiries and scientific and technologic investigations concerning mining, and the preparation, treatment, and utilization of mineral substances, with a view to improving health conditions and increasing safety, efficiency, economic development, and the prevention of waste in the mining, quarrying, metallurgical, and other mineral industries; and to investigate explosives and fuels and unfinished mineral products belonging to, or for the use of, the United States, with a view to their most efficient use; and to disseminate information concerning these subjects in such manner as will best carry out the purposes of this Act.

"Sec. 3. That the director of said bureau shall prepare, publish, and distribute, subject to the direction of the Secretary of the Interior, under the appropriations made from time to time by Congress, reports of inquiries and investigations, with appropriate recommendations of the bureau, concerning the nature, causes, and prevention of accidents, and the improvement of conditions, methods, and equipment, with special reference to health, safety, and prevention of waste in the mining, quarrying, metallurgical, and other mineral industries; the use of explosives and electricity, safety methods and appliances, and rescue and first-aid work in said industries; the causes and prevention of mine fires; and other subjects included under the provisions of this Act.

Sections, 4, 5, and 6 are as published last week, page 247.

The committee submitted a copy of the bill to the Secretary of the Interior, who has expressed his unqualified approval of it, commending especially Sections 4 and 5,

enabling the Bureau to command the temporary services of men of large experience at nominal compensation. The Secretary especially approves of the provision in Sec. 5 for exempting state governments from the payment of the fees required of private persons for special investigations, as the sums involved will usually amount to very little, but would require special legislative provision to meet these charges of \$1 to \$5 each. The committee in their report call attention to the fact that nothing in the bill authorizes any investigation of private processes for use in the preparation, treatment, or utilization of ores or minerals, nor does it authorize the Bureau to extend its investigations beyond mining operations. Section 5 is existing law, having been enacted as part of the sundry civil act. For some time the Bureau of Mines has been testing explosives at the request of manufacturers, and the provision of the present small charge for this work has operated to materially decrease the number of unnecessary requests. The fees for testing explosives were published as schedule 1 of the Bureau of Mines, June 1, 1911, and range from \$5 for a single test to \$150 for a complete official test to determine permissibility for use in coal mines. Taken as a whole, the new bill states clearly and specifically what work the Bureau of Mines may do and for what purpose. Without materially extending the scope of the Bureau of Mines, it defines it more clearly and will help in avoiding duplication of the work of other bureaus, while facilitating coöperation with them.

NEW YORK

COPPER SITUATION.—RAY CENTRAL AND RAY CONSOLIDATED.

—MONTGOMERY-SHOSONE BANKRUPT.—GENERAL MARKET NOTES.

Whether the copper situation is such as to justify the hoped-for advances in the metal and, as a reflection of such advance, a livelier and a rising market in copper shares or not, the fact remains that concentration of the principal future factors in production goes on apace, and the heavier, or rather the heaviest, of the banking interests are more and more closely identified with copper.

Recently the consolidation of the Inspiration Copper Co. and the Live Oak Development Co. furnished an opportunity to bring together several of the financial heads in the copper world upon one board of directors. The banking interests most prominently represented were J. P. Morgan & Co. and the Bankers Trust Co. of New York. Following this move comes this week the absorption of Ray Central by the Ray Consolidated. Up to the present time the history of Ray Central has not been marked with any great triumphal progress. The property was at one time, some years ago, under option to the General Development Co., the Lewisohn organization which controls the Miami and the New Keystone. After the work of some months, J. Parke Channing sprung a surprise upon the public and the shareholders in the company by recommending that the option be dropped. It had been rather taken for granted that the Lewisohns would take the Ray Central over, and the result was that a great many people were left rather high and dry, with holdings that they did not want, unless Mr. Channing and his associates were to proceed with development work. The present deal was made by Charles Hayden, of Hayden, Stone & Co., which house has been prominently identified in the financing of all the Guggenheim-Jackling-Penrose-McNeill properties, while the million and a quarter of cash which went into the Ray Central treasury was furnished by the Chase National Bank of New York. The recent underwriting of the Ray Central bond issue of \$1,800,000 was a heavy load for the underwriting syndicate, the shareholders taking only some \$83,000; as a result, it was proposed to the Ray Consolidated board that the bonds be taken over from the underwriters on condition that the Ray Central shareholders be offered an exchange of one share of Ray Consolidated for each eight shares of Ray Central. The Ray Central bond issue taken over by the Ray Consolidated is convertible into Ray Central shares at \$2 per share, as the underwriters were left

with some \$1,717,000 in bonds, which is equivalent to 858,500 shares of stock. This, with some of the larger inside holdings that have already been pledged for exchange, guarantees to Ray Consolidated a large majority of the outstanding stock of the Ray Central. A special meeting of the stockholders of the Ray Consolidated has been called to approve the issue of some 200,000 shares additional stock to be used in completing the exchange. The present capital of the Ray Consolidated is 1,400,000 shares, to be increased to 1,600,000 shares. From a mining standpoint, it is expected that the consolidation will prove of great advantage and permit the institution of many economies. The ore developed in the Ray Central ground so lies that it can easily be taken out through the No. 1 shaft of the Ray Consolidated. The engineers of the Ray Central estimate the developed ore at 7,348,000 tons, averaging 2.51% copper, a small part of which is of comparatively high grade, running a little better than 5% in copper.

The Montgomery-Shoshone, the property at Bullfrog, Nevada, in which Charles M. Schwab was the principal factor, has notified its shareholders that it is wholly insolvent. Unless the mill which was erected can be dismantled and sold to take care of existing indebtedness, the concern will be forced into bankruptcy. Mr. Schwab is at present devoting his time to doing battle for the steel tariff schedules and resisting the prospective cuts therein, evidently having relegated to oblivion all memories of Nevada mines and the Casino at Monte Carlo, each of which at one time claimed a share of his attention. The great Schwab mansion is forsaken and he lives in Bethlehem, Pennsylvania, where he is devoting his time to his steel plants. The Nevada-Utah snarl has at length landed in the bankruptcy court, where, it is safe to say, it will never be untangled. Nevada-Utah will be a bitter memory for the many followers of Lawson, but its affairs long ago reached the point where the only hope of progress was an entirely new starting point.

The sharp advance in silver is attracting much attention. The price of a little better than 60c. per ounce is the high mark since November 1907, when the market reached a level of 60½c. One factor in the present situation is the Chinese revolution, which is creating a demand for many payments in coin. A more important factor is the position of the Indian Government, which is expected to come into market to purchase bars for coinage into rupees. Both London and Bombay are speculating heavily, and it is reported to be quite a question as to whether the present holders can carry the loads they have accumulated until the demand will permit them to get out at a profit. The recent serious disturbances in Mexico nullify in large part, so far as new enterprises are concerned, the good effect of the rise in the price of the white metal. Some days ago it was rumored that the Mines Finance Co. had acquired control of the Kerr Lake property from the Lewisohns, who manage the Kerr Lake and the Wettlanfer through the Canadian Silver Mines Exploration, which is a subsidiary of the General Development Co. The report is authoritatively denied by the Lewisohn people. Robert Livermore, a son of T. L. Livermore, is now general manager of the Kerr Lake mine. Cobalt Townsite is paying an initial dividend of 5% as a quarterly distribution. The concern is a holding company and is one of the Cobalt mining companies that is owned almost wholly in England. Stewart Mining, a Coeur d'Alene mine, control of which is supposed to rest in the treasury of the United Copper Co., has been enjoying one of its spurts of activity in the Eastern market. The mine is supposed to be a valuable property, but, like all Heinze properties, seems to have a great deal of trouble getting to a point of profitable production.

The British Columbia Copper Co. reports net profits for the year ended November 13, 1911, as \$134,000, in spite of being obliged to operate for a large part of the time with Pennsylvania coke, which costs \$4 per ton more than domestic fuel. The third furnace was blown in on February 11, and the Dominion Copper Co. is expected to furnish one-third of the tonnage smelted.

General Mining News

ALASKA

COPPER RIVER

E. A. Patrick, representing Spokane stockholders in the Alaska Copper Co., recently stated at Cordova that the company is planning to carry on development on a larger scale at its property, at Mile 177, west fork of the Kennicott glacier. The property formerly was known as the Greer. The orebody has been stripped sufficiently to show ore deposits of enough value to warrant heavy investment, according to press despatches.

PRINCE WILLIAM SOUND

Development has been resumed at the Pinochle group of claims near Shoup glacier, under the direction of Ernest King, of Valdez. Some samples from the Bessie group, adjoining the Mayfield property in the Shoup bay district, assayed as high as \$1000 per ton, according to a recent report from Valdez. The third clean-up since December 16 at the Cliff mill was made a short time ago, amounting to \$10,000, stated B. F. Millard. The mill has averaged about \$1000 per day since it was put in operation.

Tony Dahlstrom and Gus Neuman have purchased from Olaf Olson his one-third interest in the Olson, Anderson & Gustafson property of Shoup bay. A sample from recently discovered ore in the Midas Copper Co. mine, in Solomon gulch, five miles from Fort Liscum, assayed 16½% copper, \$1.20 to \$10.80 in gold, and 50 to 75c. silver per ton, says a despatch from Valdez. The adit in which the ore was found is in 105 ft. Development will be continued until July 1, when actual production will be started. The Midas company, which is not incorporated as yet, includes E. J. Deviney, George Treat, George Baldwin, W. M. Wilson, A. Grigsby, John Fienbloom, and Joseph Plant, all of Valdez.

THE TANANA

Gus Raymond is said to have discovered gravel that pays 5 to 15c. on Beaver creek, a tributary to the south fork of the Big Chena river. J. E. Carlson has started on a prospecting trip to Valdez creek, at the head of the Susitna river, in the interests of the Lucky Hill M. Co., of which he was one of the organizers.

ARIZONA

COCHISE COUNTY

The Commonwealth mine at Pearce is being prepared for the resumption of development. Llewellyn Humphreys is manager of the property.

GILA COUNTY

The Inspiration Consolidated bond issue subscription rights were allotted on the *pro rata* basis of the stock outstanding on February 1, when there was found to be issued and outstanding 696,000 shares of stock. The bond issue is for \$6,000,000. Holders of 116 shares of stock are entitled to subscribe for one \$1000 bond, or holders of 58 shares of stock for one \$500 bond.

The construction and development plans of the Inspiration Consolidated are still hanging fire. The greatest obstacle to the final settlement of these plans seems to be the inability of the officials of the Arizona & Eastern Railroad Co. to come to an agreement with property owners along the proposed right-of-way for the extension of the railroad from its present terminus at Miami, near the Miami mine, to the Inspiration and Live Oak mines, a distance of about 1½ miles. In the condemnation proceedings recently instituted in the territorial district court at Globe by the Arizona & Eastern, the court decided that the company must give a bond of \$13,500 before it could proceed with construction. This the company declined to do, and, rather than take the chance of an excessive award by a jury when the case shall have come to trial in the new state court, it is now conducting negotiations with the property owners outside of court. W. H. Aldridge, managing director of the Inspiration Copper Co., is now at the mines.

PINAL COUNTY

The Ray Con. Copper Co. in January produced about 3,000,000 lb. of copper, as against 2,600,000 lb. in December. The company was handicapped through the fact that the mill work has been ahead of the mine development. On April 1 the company will ship its concentrate to the nearby Hayden smelter, instead of to El Paso. It is believed that this arrangement will reduce the cost of production by 13½c. per pound.

YAVAPAI COUNTY

Development has been resumed at the Square Deal M. & M. Co. and the Sure Shot properties in the Cherry Creek district, says a Prescott report. L. N. Wombacher is manager of both mines.

YUMA COUNTY

Press reports assert that the Tusearora M. & M. Co. has discovered a 7-ft. vein of ore assaying about \$25 per ton on its property near Parker. John Jarvis is superintendent for the company.

CALIFORNIA

AMADOR COUNTY

The shaft collar of the Bunker Hill mine collapsed in the recent accident which imprisoned 69 miners for about

FORT BIDWELL MINE, MOHOC COUNTY.

21 hours. The accident was caused by the breaking of the cable used in hauling a loaded skip up the inclined shaft. The skip jumped the track and the shaft partly collapsed, tilting with debris at the 200-ft. level, which was used as a drainage adit. The shift boss rode up on the skip, and only the fact that he stepped off at the collar of the shaft as the skip emerged, saved his life.

MOHOC COUNTY

Richard Mason, in sinking a winze on the Mountain View claim of the Fort Bidwell Consolidated, at Fort Bidwell, discovered a 2-in. stringer remarkably rich in free gold, according to a recent report. The property is in the High Grade district.

NEVADA COUNTY

Murray I. Scott, lessee on the A. McGee property near the Eureka, has found a rich ore-shoot 30 ft. from the surface, according to a report from Grass Valley.

The North Star M. Co. has purchased self-dumping skips to replace the old ore cars in the Providence mine, of the Champion group.

PLUMAS COUNTY

The Jameson mill, near Johnsville, has been closed on account of the lack of water. The mild winter has caused fear that other properties may be forced to shut down, unless there comes a heavy fall of snow.

SAN BERNARDINO COUNTY

The Death Valley Arealvada Con. M. Co., says a report from San Bernardino, has development under full headway on its property, situated near Cima. Water-power has been developed, and a mill built on the property, as well as other improvements. In the eastern end of the county, in Whipple 'wash,' twenty miles north of Parker, Arizona, recent discoveries on the property of the Golden State M. Co. have brought a number of prospectors into the district. Kit Carson is manager for the Golden State company.

SHASTA COUNTY

(Special Correspondence.)—The Delta Con. Gold M. Co. is planning to erect a mill soon. The company reports a good reserve of fair-grade ore, but its treatment offers some difficulties. It is planned to augment the mill with a cyanide plant. S. D. Furber is manager of the property, which is in the Dog creek district, northwest of Redding. Reports that the First National Copper Co. was to resume operation at Coram were set at rest a few days ago, when E. B. Braden, manager for the company, stated that no effort was planned, owing to hostility on the part of farmers. The Noble Electric Steel Co. is sending out high-grade pig iron from the Heroult electric smelter. Two furnaces are producing. M. E. Dittmar and associates plan to prospect their holdings at Igo during the coming spring. A diamond-drill will be installed. The Bully Hill Copper Co. has concluded a series of experiments for the electrolytic smelting of copper and zinc ores. It is reported results have been encouraging, but nothing of an official nature has been given out. The Bully Hill ores carry a large percentage of zinc, with some gold and silver.

Redding, February 12.

SIERRA COUNTY

Valuable ore last Sunday was discovered in the main adit of the Kate Hardy mine, near Forest. Will D. Beggs of San Jose is operating the property.

TRINITY COUNTY

(Special Correspondence.)—The Alta Bert Gold Dredging Co. has placed in commission its first dredge here. The hull is 98 ft. long, 42 ft. wide, and 9 ft. 4 in. deep, and was built of red fir sawed on the ground. The dredge is electrically operated, has 7½-cu. ft. buckets, and was built to dig 25 ft. below the water-line. It can develop 345 hp. The machinery was taken from the old Scott river dredge.

In 1900 a small dredge was built here by the Urie Machinery Co. of Kansas City. The dredge, which had 2½-cu. ft. buckets, and which was steam-operated, was found too light, and was abandoned after three summers' operation.

Trinity Center, February 8.

The Globe M. Co. has filed suit in San Francisco to secure an accounting by W. D. Pinkston, superintendent for the company from 1907 to 1910, for \$60,000 alleged to have been misappropriated.

TUOLUMNE COUNTY

(Special Correspondence.)—The New Providence M. Co. has been incorporated to develop three claims situated just east of the old Providence mine. Its capital stock is \$500,000. The officers are M. J. Corbett, president, George W. Mooney, vice-president, and T. L. Bibbins, secretary. The claims are but slightly developed, two short adits having been driven, in both of which 6 ft. of low and medium-grade ore was found. The outcroppings range

in width from a few feet to 75 ft. William Floyd, of Soulsbyville, who will be superintendent, states that work will begin within 60 days, and that the plans are to drive a 1000-ft. adit.

Tuolumne, February 10.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—H. C. Reno, who recently purchased the Wisconsin and Corry City mines for a syndicate of Eastern capitalists, has a force of men at work in repairing the 250-ton Pelican mill. Ore treatment will start March 1. Mont Tong, manager of the St. Paul property on Green Lake mountain, expects to resume work March 1. The adit will be driven 600 ft. to intersect the St. Paul vein that is supposed to be an extension of the Colorado Central.

Georgetown, February 10.

JEFFERSON COUNTY

(Special Correspondence.)—Through donations of machinery made by various manufacturers, it will be possible to completely equip the concentration department of the Colorado School of Mines. William G. Haldane will be in charge of the work. Recently \$12,500 was turned over to the school for equipping the ore-testing plant. The building for this department was built a year ago, and \$50,000 was appropriated by the legislature for securing the necessary machinery. One-fourth of the sum is now available.

Golden, February 10.

SAN JUAN COUNTY

I. Mather and John Cloucher have secured a 4-year lease on the Alda group from Robert Hoffman, says a report from Silverton, and have started development.

TELLER COUNTY (CRIPPLE CREEK)

The January production of the Cripple Creek district was 69,726 tons of ore, valued at \$1,285,971, an increase over the December output of about 2000 tons, although a shortage of water allowed the Stratton's Independence mill to run only part time. The New Portland mill on Battle mountain treated 13,000 tons of ore, the largest amount since it was put in operation a year and a half ago. The Portland mill at Colorado Springs treated a smaller amount than in December, but the ore had a higher average value than the 1911 figure. A reduction in tonnage there was caused by the change from the chlorination to the cyanide process. The Colburn mill, Battle mountain, of which A. M. Warwick is superintendent, treated 3000 tons. The Golden Cycle mill, Colorado City, had the largest tonnage in its history, treating 33,700 tons of ore. Its capacity is 35,000 tons per month. It is rumored that this mill will be enlarged to handle an increased output from its own mine. The production of the district has been tabulated as follows by the *Cripple Creek Times*:

Mill.	Tonnage.	Av. Value.	Total.
Golden Cycle	33,700	\$20.00	\$ 674,000
Portland	8,800	23.00	202,400
Smelters	3,800	65.00	237,000
Stratton's Independence ..	5,226	3.06	15,991
New Portland	13,000	2.97	37,610
Colburn	3,000	3.75	11,250
Wild Horse	1,000	5.00	5,000
Kavanagh	1,200	2.60	2,720
Grand total	69,726		\$1,285,971

The January production of the El Paso mine was 130 cars of ore averaging \$25 per ton. The production was as large as the ore-houses could handle. According to the figures by T. R. Countryman, the Roosevelt drainage adit was driven 200 ft. in the 31 days of January. The weirs at the portal of the adit have been washed away, making a measurement of the flow difficult. Mr. Countryman estimates the flow at 9500 gal. per minute. The New Portland mill made a new record for itself January 6, when it treated 503 tons of ore in the 24 hours. The United Gold Mines Co. in January produced 29 cars of ore. The

Vindicator Con. Gold M. Co. produced 72 cars, slightly over 2000 tons. The main shaft of the Vindicator, on company account, produced 60 cars of this amount. The Cresson Con. M. Co. produced 1700 tons of ore averaging \$25 per ton. The Golden Cycle M. Co., February 1, paid a monthly dividend of 2c. per share. The Granite Gold M. Co. produced about 2000 tons of ore in January. The ore averaged about \$20 per ton.

The old board of directors won the contest for control of the Isabella company, although James F. Burns, of Colorado Springs, was elected to the directorate. The board now comprises E. E. Quentin, A. C. Gardner of Denver, E. M. Kirton, James F. Burns, and Ira Harris of Colorado Springs. The annual stockholders' meeting of the Portland Gold M. Co., held at Cheyenne February 6, resulted in the reelection of the entire board of trustees, headed by Frank G. Peck of Colorado Springs.

The Trilby Mines Co. in January produced about 1000 tons of ore. During the same month the lessees on the Acaia Gold M. Co.'s property produced 400 tons, and Frank Caley, lessee of the Jerry Johnson mines, Ironclad hill, 40 cars. The annual meeting of the Ironclad M. & M. Co. will be held at Denver March 5. It is stated that a plan for paying off the indebtedness of the company will be considered.

IDAHO

LEMHI COUNTY

M. M. Johnson's plans for the big adit to connect the Gilmore Mining, Pittsburg-Idaho, and other properties directly with the railroad, have been approved by the capitalists back of the project. As soon as a new company, separate from the mining companies operating in the district, can be organized, actual construction will be started. Those back of the plan are heavily interested in the mines.

SHOSHONE COUNTY

The Stewart M. Co. has started construction work on the tramway from the new adit on Deadwood gulch to the Oregon-Washington Railroad & Navigation Co.'s tracks, west of the Bunker Hill & Sullivan mine. The tram will be operated by gravity to carry the loaded cars to the bins, now under construction.

J. W. Weyer, of Wallace, reports that a good supply of water is now available for power at his property on Cedar creek. The shaft is down nearly 70 ft. below the adit level. Five feet of concentrating ore has been exposed at the bottom of the shaft.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—The production of the Anaconda company for the month of January was 26,350,000 lb. of copper, according to the official figures. The December output was 24,400,000 lb., and was the largest monthly production of last year, the next highest being in August, when the production was 22,500,000 lb. In all those figures the production of the North Butte and Tuolumne companies are included, as the ore of both companies is treated at the Washoe smelter. They have been averaging about 2,750,000 lb. per month, of which the North Butte company turned out 2,000,000 lb. Allowing 1,000,000 lb. for the East Butte company, the total production of this district during January was 27,350,000 lb. During the early part of February the amount of ore going to the Washoe smelter has been considerably above the average per day, but according to Mr. Thayer, the president, the production will be kept around the 26,000,000-lb. mark during the year. Butte, February 11.

The Anaconda made a new record for itself, February 3, when it shipped to the Washoe smelter 271 cars of ore, containing about 13,500 tons. The previous record was 261 cars.

NEVADA

CLARK COUNTY

It is reported that an orebody assaying about \$15 per ton has been discovered on the 380-ft. level of the Princess

shaft of the Searchlight-Spokane M. M. Co. The mill will be put in operation soon.

A cyanide plant is to be added to the Lucy Gray mill, according to advices from Searchlight. The property, which is equipped with a Lane Chilean mill, is situated in the Sunset district, and is in charge of Carl Anderson. The general office of the company has been moved to Los Angeles. F. J. Gollmer has levied a \$5000 attachment on the Treasure Gold M. Co. property.

ELKO COUNTY

It is reported that the Harriman system will build from Rogerson, Idaho, to Contact, in the northern part of the county.

ESMERALDA COUNTY

The Silver Pick Consolidated has intersected a new vein, it is reported, on the 120-ft. level, 12 ft. from the shaft. The shaft now is 133 ft. deep.

The Florence Consolidated, which has a lease on the Western Union No. 1 claim, is reported to have discovered rich ore 900 ft. south of the original Antelope district find. The company is a close corporation. The Goldfield

TONOPAH BELMONT MILL, NOW UNDER CONSTRUCTION.

Merger shaft has passed the 600-ft. level, after having been sunk 115 ft. during January. The compressor has been installed. At 530 ft. the shaft passed through quartz, which, however, was not pay-ore.

HUMBOLDT COUNTY

The Nevada Superior Mines Co.'s 75-ton concentrator, 15 miles from Humboldt, has been placed in commission. J. W. Geiger is manager for the company.

LINCOLN COUNTY

The president of the Nevada-Utah M. & S. Co. has filed in the United States District Court company schedules showing total liabilities of \$185,033, of which \$140,000 is secured, \$44,256 unsecured, and \$750 due for taxes, says the *Boston News Bureau*. Nominal assets are \$309,488, of which \$307,743 is for debts due the company. Among the secured creditors is the National Bank of the Republic of Salt Lake City, \$21,500. Among debts due to the company are those of Nevada-Utah M. Co., \$222,341, and the Imperial Gold & Copper M. Co., \$17,434.

LYON COUNTY

According to an announcement by W. C. Orem, the Bluestone mine is to ship 100 tons of ore per day to the smelter.

NYE COUNTY

Covering the side of the upper part of the main building of the Tonopah Belmont mill, shown in the cut, will be started in a few days. The ore-bins back of the mortars have been completed, and the general construction has so far advanced that the management is anxiously awaiting the delivery of more machinery.

The Round Mountain M. Co., in the quarter ended November 30, 1911, treated in its mill 15,936 tons of ore at a cost of \$65,710. The net operating profit was \$80,034. At the close of the period named, the company had on hand \$107,566, according to the quarterly report of J.

R. Davis, president and general manager for the company. The Gibraltar M. Syndicate, operating in the Bullfrog district, complying with the Nevada mining law, has reported that on January 1, 1911, the company had on hand \$470, and during the year has received \$199. Expenses amounted to \$401, leaving a balance at the end of the year of \$268.

The production of the Tonopah district for the week ended February 10 was as follows: Tonopah M. Co., 3300 tons of ore; Tonopah Belmont Development Co., 2100; Montana-Tonopah M. Co., 1051; Tonopah Extension M. Co., 945; West End Con. M. Co., 775; total, 8171 tons, valued at \$204,275.

STOREY COUNTY

The Belcher Silver M. Co. recently held its annual meeting, and the old board of directors was reelected with George S. Sturges as superintendent. The annual report shows that work for the year closed was confined to the 200 and 300-ft. levels. At the Yellow Jacket mill 2655 tons of ore from these levels was treated, and 310 tons of ore from the 1400-ft. level. The 'recovered value' of the ore was \$8388.

The Ophir produced during the week ended February 10 about 359 tons of ore averaging \$33.61 per ton. The Mexican mill treated 398 tons of ore with a gross assay-value of \$71.44. The new classifier has been installed in the mill. The tailing for the week averaged \$2.29. The Crown Point produced ore valued at \$4300. The shipments for the week included 884 tons to the Yellow Jacket mill. Pumping was carried on as usual.

WHITE PINE COUNTY

The Giroux Con. Mines Co. has a 5-year contract with the Steptoe Valley S. & M. Co.'s smelter for shipments of 900 tons of ore per day as a minimum, and 1200 tons as a maximum. The contract is to become effective May 1. In the Giroux report for the year ended December 31, T. F. Cole, president of the company, stated that there was 4,000,000 tons of ore averaging 2¼% copper in the Bunker Hill group alone. The total developed ore, up to January 1, 1912, was 10,291,000 tons averaging 2% copper. In addition to this, there was 6,600,000 tons of ore averaging 1.65% copper. The company has a balance of \$180,000 in cash and bonds. It is believed that a 9½¢ cost can be maintained. The Butte & Ely Copper Co., over which the Giroux company has control, has an available cash balance of \$250,000. While sinking the Giroux and Alpha shafts, together with the repairs to the Giroux shaft since the fire last August, cost a large sum, it is claimed that there is sufficient high-grade direct-smelting ore in these workings above the 1400-ft. level to more than compensate for the expenditure. It is not believed that the Giroux bonds mentioned will be issued, as arrangements have been made for any temporary financing that may become necessary. Giroux stock was asked in exchange for Butte & Ely Copper Co.'s stock at a meeting of the shareholders in the latter company recently.

The U. S. Geological Survey has announced the publication of a preliminary edition of the geologic map of Ely and vicinity. The final publication, now in preparation, will be a professional paper describing the geology and ore deposits of the district. The boundaries of the formations indicated in the preliminary map are final, but the subdivisions of the Paleozoic sedimentary rocks, consisting of limestone, shale, and quartzite, are not indicated, nor the system of faults which intersect them. The map is intended to show accurately the boundaries and relative positions of the various areas of Paleozoic sedimentary rocks, the igneous rocks (monzonite and monzonite-porphry) intrusive into them, and finally the rhyolite tuffs and lavas of Tertiary age which in places cover the older rocks.

NEW MEXICO

GRANT COUNTY

(Special Correspondence.)—Two units of the Chino Copper Co.'s mill are in constant operation. The third unit, owing to unavoidable delay in shipping the machinery, probably will not be in commission before April 1.

Hurley, February 10.

LUNA COUNTY

A report from Denning states that J. A. Kealey, sheriff, and Albert Schultz have discovered copper ore valued at about \$15 per ton on their holdings in the Tres Hermanas district.

SIERRA COUNTY

A pump has been ordered for unwatering the Dude Good Luck mine, near Lake Valley. After the unwatering has been accomplished the shaft will be sunk from the 300 to the 500-ft. level. The Black Range M. & M. Co. has been organized to develop 11 claims in the Tierra Blanca district, says a report from Hillsboro. John McFarland, of Omaha, leads the incorporators of the company, which is capitalized at \$1,125,000, and which acquired the property from S. A. Hoisinger.

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine M. Co.'s clean-up for the last ten days of January yielded 9450 oz. gold and silver bullion, with a concentrate product of 9250 lb. The past week 694 tons of ore was milled. The ore-shoot discovered several weeks ago, remarkable for its size and richness, is producing a large amount of unusually high-grade milling ore. The new oil equipment recently installed is proving satisfactory and is saving at least \$100 per day in power cost. The Alberta M. Co.'s drift on the vein is now in ore of an average milling grade. The Oaks Co. is erecting a gasoline hoist at the South shaft on the Pacific mine which will be in readiness for operation within a week or ten days. The adit on this mine had reached a point 232 ft. from the portal on February 1. Some good ore has been taken from the adit, and the South shaft is yielding several tons per day which is sent to the Deadwood mill for treatment. The drift from the North shaft, 47 ft. deep, has been extended south 25 ft. Two shifts are employed. One unit of the De La Vergne engine equipment at the Socorro Mines is being tried out, and the rest will be turned over soon.

Mogollon, February 9.

UTAH

JUAB COUNTY (TINTIC DISTRICT)

Development will be resumed on the Tintic M. & Dev. Co. property, through the Sioux-Ajax adit, says a Eureka despatch. J. W. Moodie is manager for the company, a close corporation which has its principal holdings in the Bingham district.

Two raises from the 600-ft. level of the Iron Blossom have intersected ore. The present production of the Iron Blossom is said to be about 300 tons of ore per day, the ore ranging from \$12 to \$50 per ton. It is reported that the Iron Blossom company is earning about \$120,000 per month. A rumor that the Swansea is to shut down has been denied. It is rumored that development may be resumed at the Plutus property.

PIUTE COUNTY

J. W. Young, manager of the Bully Boy & Webster property at Marysvale, recently stated that the mill being constructed there will be in operation before the end of March. Some of the machinery is new, while some was taken from the Bullion Canyon property, four miles away. There is said to be more activity in the Marysvale district than there has been for some years.

SUMMIT COUNTY

H. G. McMillan, general manager for the Daly West company, has issued a statement that the shut-down of the mill is only temporary, having been caused by a lack of water.

WASHINGTON COUNTY

B. Carpenter, of Bloomington, Joseph Riding, and Frank Benly recently reported the discovery of rich copper ore on their property, about 12 miles southwest of St. George.

WASHINGTON

SPOKANE COUNTY

Robert J. Maclean, secretary of the Spokane Chamber of Commerce, has advised J. F. Callbreath, secretary of

the American Mining Congress, that a guaranteed fund of \$5000 has been subscribed to bring the 1912 convention to that city the latter part of November. A formal invitation also has been forwarded. An additional \$5000 will be raised by public subscription, in the event Spokane is chosen, to entertain the delegates on a trip to the principal mines in the Coeur d'Alene, in Republic, and in the Sloean district of British Columbia.

CANADA

ONTARIO

January shipments from the Cobalt district amounted to 1237 tons of ore, a figure slightly lower than that for December and for the monthly average of 1911. The Cobalt Townsite company paid a dividend of 5% on February 12, the dividend requiring the disbursement of about \$50,000. The company in 1911 shipped 720 tons of ore. A. C. Bailey is manager of the property. The Coniagas established a new record for itself with the shipping of 172 tons of ore during January. The Winyah Gold M. Co. has been formed in the Poreupine district to take over four claims in the Mountjoy part of the district owned by R. A. Cartwright. A. W. Grierson is manager for the company. Owing to the lack of water, the Apex mine, Poreupine district, has stopped operation. The Nipissing mill, which had been closed two weeks for repairs, has resumed shipping, and in the week ended February 3 shipped 43 bars of bullion.

MEXICO

CHIHUAHUA

An aerial tramway has been ordered for connecting the Presena mine of the Alvarado M. & M. Co. with the Palmilla mill. Thirty-two towers will be used for supporting the rope, which will run 12,500 ft. between terminals. The discharge terminal will be of steel, and the towers of lumber. The capacity is to be 350 tons of ore per 10-hour shift. The Alvarado company is considering the resumption of development at the San Juanico mine, west of the Palmilla mill, now operated only in a small way by lessees. The mine has a 1250-hp. hoist. The shaft is 280 ft. deep. The first of the two tube-mills for the Alvarado mill is awaiting the installation of the motor, and the new Dorr thickener will be in commission in a few days.

The El Cristo property, Santa Eulalia district, has resumed operation. Norval J. Welsh is manager.

The production of the Parral district for the week ended January 20 amounted to 13,233 tons of ore, of which 3233 tons was shipped to the smelters and 10,000 tons was treated in the district plants. The production for December was 61,249 tons of ore.

The La Fe M. & M. Co. will resume operation on its properties in the Guadalupe y Calvo district. M. W. La Fayette, of Chicago, Oklahoma, is in charge for the company.

SONORA

(Special Correspondence.)—It is reported that the reorganization of the various Cieniguita companies is about completed on a very satisfactory basis, that the Mexican company will be clear and free of all indebtedness of every kind and character, and that the debts and obligations of the various holding companies will be taken care of. It is said also that the stockholders of the different holding companies will be completely protected in their interests. It has been authoritatively denied that John B. Farish, whose name has been mentioned in connection with the Cieniguita companies, is in any way interested in the corporations or the reorganization of them.

Sahuaripa, February 9.

The Empire M. Co. is planning to build a 3-unit Pittman mill on its Gold Cross property, adjoining the Pasquana mine, southwest of Cananea. The Muehade Grande M. Co., backed by New York investors, will build a concentrator on its property, near Alanos, and also will construct a railroad from the mine to Victoria, a station on the Southern Pacific of Mexico, according to recent advices from Cananea. At Tesla, five miles north of Navajoa, the Sisson interests will build the first of several concentrating plants to be erected on the west coast.

Among the Copper Mines

The GREENE-CANANEA COPPER Co.'s January production was about 5,500,000 lb. of copper.

IT IS RUMORED that the second unit of the Mason Valley smelter will be blown in by March 1.

COPPER EXPORTS so far this month amount to 7248 tons, according to New York mail advices of February 8.

IT IS REPORTED THAT THE CAPE COPPER Co., the largest copper producer in South Africa, made a net profit last year of about \$300,000.

The CALUMET & HECLA M. Co., has ordered from the Allis-Chalmers Co. a 10,000-kw. turbine engine for its stamp-mills at Lake Linden. This will be the largest mixed-pressure turbine engine in the United States and will cost about \$250,000.

THE A. S. & R. Co. declared dividends at the regular quarterly rates for the last two months of 1911, of 11 $\frac{1}{2}$ % on preferred and 2% of 1% on common stock. The preferred dividend is payable March 1 and the common dividend March 15. The dividends were declared on two months instead of three to conform with the calendar year, and the next will be for the first quarter of 1912.

The CANANEA CON. COPPER Co. has acquired control of the Superior-Bonanza M. Co. and is considering the construction of a railroad from that property to the railroad station at Immris. One of the shafts will be sunk from the 450 to the 650-ft. level, and development will be started as soon as practicable on the 450-ft. level, where some ore has been blocked. The Superior-Bonanza company is sometimes known by its former name, the Sonora Bonanza Mining Company.

January Copper Review

By MISHA E. APPELBAUM

During January copper had a slight reaction, but the first hands, being sold out, did not care to reduce their quotations, with the result that the dealers and speculators took all the orders in sight from 14 $\frac{1}{2}$ ¢, down to 11¢. As expected, however, when the January statement was published showing a reduction in the visible supply of 23,000,000 lb., copper immediately jumped to 14 $\frac{1}{2}$ ¢, at which figure, at this writing, there is a very active demand, and with every indication that the metal is going higher.

Were it not for the fact that the general business situation has not yet shown any improvement, it would be a difficult matter to keep copper at the present level. A visible supply in the United States of 66,000,000 lb. means about one month's consumption. The visible supply abroad is larger, but even if that could be shipped to the United States, it would take several months until the refined copper would be ready for delivery. Statistically, therefore, copper is in a stronger position than at any time since 1907; in fact, it is in a stronger position than in 1907, for in that year we were at the end of a boom which lasted several years, while at present we are on almost the fourth year of a business depression, and even if the improvement does not set in for quite a few months, when it does come we will have a situation without any surplus of copper. Of course, as soon as copper crosses 15¢, undoubtedly production will be increased, and this, together with the production from the new mines, would probably keep the market from advancing more than a cent or two; but I cannot help believing that the copper business has seen its worst, and that even without any marked improvement in business, the average price of copper for this year will show a very marked improvement over the last few years, and will even be above the average for the past fifteen years.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

HOWLAND BANCROFT is at Denver.

JOHN G. BARRY was at Parral recently.

FREDERICK LYON was at Kennett recently.

G. W. METCALFE was in San Francisco last week.

T. G. JANNEY was in San Francisco during the week.

C. E. BOYDSTON has returned to Berkeley from Arizpe, Sonora, Mexico.

J. P. HUTCHINS is examining platinum deposits in the Ural mountains, Siberia.

G. W. SCHNEIDER recently examined mining properties near Washington, D. C.

H. C. PARKER has been examining the Muncy Creek mines, northeast of Ely.

M. OTAGAWA has returned to Ashio as manager for the Furukawa Mining Company.

GEORGE A. GUESS has accepted the professorship of metallurgy at Toronto University.

ALVIN B. CARPENTER has moved his office to the California building, Second street and Broadway, Los Angeles.

HOWARD POILLON has resigned the position of manager of the Vanadium Mines Co.'s mines and plant at Cutter, New Mexico.

HENRY D. BODDINGTON has gone to London on professional business, and expects to be absent from El Paso, Texas, about three months.

T. H. JENKS is making examinations in the Arizpe district of Sonora, and will then go to New Mexico, expecting to return to Denver early in March.

GEORGE GILMORE and V. M. WEIL, president and general manager, respectively, of the Standard Amalgamated Exploration Corporation, have been visiting Angels Camp.

NORVAL J. WELSH is manager for the Mexican Mines Development Co. and has an office at 229 Avenida Independencia, City of Chihuahua, for general examination work.

Obituary

JEROME A. SNEDEKER, a well known mining engineer and mine owner of Denver, died in that city on February 10. He came to Colorado in 1881 and settled at Aspen, afterward coming to Denver, where, in association with A. E. Reynolds, he practised as a mining engineer with material success. Recently, while on a visit to Duluth to attend a meeting of the Giroux Consolidated Copper Mining Co. he contracted ptomaine poisoning and passed away after a brief illness.

JOHN WILLIAM QUICK, a well known citizen of San Francisco, who died January 7, was born in Ireland in 1839. He came to California in 1854 and engaged in the iron rail manufacturing business. Seeing that there was a demand for screens for mining machinery, he started in the business of manufacturing them, inventing special machinery and improving methods of punching steel, sheet iron, and copper. Success marked his efforts, and the superiority of his products made his name well known wherever mining was carried on. His thorough business methods and integrity made for him many friends. He belonged to the Chamber of Commerce and the Merchants Exchange and was always a worker for the uplift and progress of the city of his adoption. Mild and gentle in his manner, never aggressive and always forgiving, he passed his days loved by his fellowmen. His judgment was remarkably clear and was often sought after. He was a self-made man in every sense of the word and was proud to belong to that little band of Argonauts that are passing so rapidly away.

The Portland Gold Mining Company

The annual report of the president of this company, F. G. Peck, notes numerous changes in the mine and mills at Victor and Colorado Springs in the year ended December 31, 1911. The process of treatment at Colorado Springs has been changed from chlorination to cyanidation, with material reduction in the cost of treatment. At the Victor mill, an increase in capacity, due to the readjustments made and others now about completed, will also reduce the cost of treatment. The tailing from this mill has heretofore been stacked on the surface, but it is now used to fill old stopes. This reduces the cost of taking care of the old stopes and keeps the surface entirely free for mining operations. The Portland mine is now free from water, due to the success in cutting several water courses by the Cripple Creek deep drainage tunnel, and preparations are being made for mining on the lowest level, where four ore-bodies are exposed.

The Victor mill was erected for the express purpose of treating the low-grade telluride ores, without roasting, using cyanide of potassium in connection with the 'Portland process.' During the past year changes were made which have brought about a marked increase in capacity. In January 1911 the mill was able to treat only 8052 tons, but in December it handled 12,285 tons, of a gross value of \$35,432.15, or an average value of \$2.80 per ton. Of this amount, \$28,533.73, or 80.5%, was recovered the cost of treatment at the mill being \$1.1317 per ton. During the entire year there was treated at this mill 120,961 dry tons of reject, or waste rock, of a gross value of \$424,489.15, averaging \$3.51 per ton. Of this amount, \$345,567.98 was recovered, this being an extraction of 81.4%. The net profits at the mill for the year were \$128,738.72, this profit being derived solely from what hitherto has been worthless rock. The profits of this mill will be a very important item in the future, as a sufficient tonnage of this ore is available to keep the mill running for a number of years to come.

At Colorado Springs the mill management for some time past has recognized that the cyanide process is the most up-to-date method for the chemical treatment of gold ores that require roasting, and it has recommended the use of cyanide of potassium in place of chlorine gas as a solvent for gold. This substitution has long been under consideration, and the change is now being made and will be completed about the middle of March. The plan adopted is to treat the ore as heretofore until it reaches the hoppers over the chlorination barrels; here the ore will be diverted to tube-mills and slined in cyanide solution, the pulp passing to two 200-ton Merrill filter-presses for filtering. These presses are similar to those used at the Homestake mill in South Dakota, where a world's record for efficiency and low cost of operation has been made. The rich gold solution from these presses will be precipitated on zinc-dust, which has proved so economical at the Victor plant.

Mine operations for the past year have been conducted as during the previous year. Twenty new stopes have been opened and more ore placed in sight than was taken out during the year. In mining the shipping grade of ore for the Colorado Springs mill, the stopes were at the same time stripped of the low-grade ore for the Victor mill. The low-grade ore from the mine, together with the reject from the ore-houses, was practically sufficient to supply the Victor mill, but when necessary the dump was drawn upon to keep the mill running at its full capacity. During December work was started preparatory to developing the ore that has been under water since the pumps were pulled on July 1, 1909. This is of better average grade than that mined and shipped during the past year. The cost of mining operations during the past year was increased by the expenditures made to secure economy in future operations and covering plans for filling stopes, and some necessary rebuilding. On account of the troubles arising from fires and bad gases at various mines, life-saving and

fire apparatus has been bought. The United States Bureau of Mines officers spent sufficient time at the mine to drill 20 men to handle this apparatus, and each of the men received certificates as to their competency.

Up to January 1 the known permanent drainage from the Portland mine by reason of the deep drainage tunnel, was about 80 ft. The total contributions of the Portland company toward defraying the expense of driving the tunnel have been about \$60,000. If the property is drained to the tunnel-level, which is about 730 ft. below the present workings of the mine, the cost for drainage will be less than \$100 per vertical foot. When general mining operations were last conducted below the water-level, the cost for permanent drainage secured by pumping was \$6500 per vertical foot. The heading of the deep drainage tunnel is now in open seamy ground, and another large water-course should be cut within 500 ft. The flow from the tunnel is now about 10,000 gallons per minute.

The net profit for the year was \$380,579.35. The total cost of the Victor mill was \$338,580.96, and the profit of \$128,738.72 for the year 1911 shows a return of 38%. On January 1, 1912, after all bills and costs of operation for the year had been paid, the available assets were of the cash value of \$346,066.01, consisting of ore in the bins and paid for, \$133,338.15; storehouse supplies bought and paid for, \$115,704.31; and cash in the bank, \$97,023.55. Development during the year amounted to 9520 ft. and the total to date is nearly 45 miles. Total production has been 1,318,262 tons, with a gross value of \$32,827,058, from which dividends to the amount of \$8,917,080 have been paid.

OPERATION FOR 1911

Gross value of ore mined and shipped	\$1,110,054.05	
Gross value recovered by new mill		345,567.98
Net cost of mining and milling..	\$1,114,708.24	
Gross profit on operation.....	370,913.79	
	\$1,485,622.03	\$1,485,622.03

THE iron ore mines near St. Olga, in Siberia, produced 2000 tons of magnetic iron ore in 1910, as against 1000 tons in 1909.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

LIABILITY FOR INJURY TO SURFACE

Where a vendor sells and conveys coal in place with the right to enter, excavate, and remove all coal purchased, the grantee is not liable where the removal of all the coal necessarily causes the surface to break or subside.

Armstrong v. Maryland Coal Co., (West Virginia)
69 Southeastern, 195. October 1910.

FAILURE TO PERFORM ASSESSMENT WORK

A failure to perform the annual assessment work on a mining claim does not of itself work a forfeiture of the claim. It only permits a re-location and cannot aid an adverse location which was made prior to the year in which the failure occurred.

Bingham Amalgamated Copper Co. v. Ute Copper Co.,
181 Federal, 748.

INJURY TO MINER—KNOWLEDGE OF INCREASED DANGER

Whether or not the owner and operator of a mine owed a miner of only two months' experience in an iron mine, and with the knowledge he had gained of the character of the work in which he was working, the duty of warning him of the increased danger of the falling of a large body of ore from the roof of a raise, because the timbering had been delayed for six hours longer than usual, is a question of fact which the jury must determine from all the circumstances in the case. But if the miner knew of the increased danger because the timbering was delayed six hours longer than usual, or if in the exercise of ordinary prudence, he should have known of such danger, he cannot recover.

Hosking v. Iron Mine Co., (Michigan) 128 Northwestern, 777. December 1910.

MINING LEASE OF INDIAN LANDS

The United States statute authorizes the leasing of Indian allotments within the limits of the Quapaw agency, subject to the condition that such lease should not extend for more than ten years for mining purposes. Under this statute an Indian allottee has power to lease his land in any manner and for any consideration, except that the term cannot extend beyond the prescribed time. And where an Indian leased his allotment for mining purposes for ten years, but before the expiration of such lease he granted another lease to the same person for a similar term to run concurrently without accumulation of periods, the second lease operated as a surrender of the first, and was therefore not a violation of the statute.

United States v. Abrams, 181 Federal, 847.

DUTY OF MINE OWNER TO FURNISH SAFE PLACE FOR MINER TO WORK

The doctrine as to the duty of a mine owner or operator to furnish a safe place for miners to work has no application where the miners themselves are engaged in construction of a new shaft by excavation and timbering, and where the use of a platform is only an incident in the preparation of the shaft in which ordinary mining operations are to be carried on while the shaft is in process of construction. But the mine owner in furnishing planks for use as staging while such new mining shaft is being constructed, owes to the employees using the staging the duty of furnishing material reasonably fit for the particular purpose; and if he furnishes material which in its nature is unfit for the work for which it is used, an inexperienced servant or miner who has no knowledge of such unfitness, and is injured by the falling of the platform, may recover. But in such case the mine owner is not liable for mistakes or negligence in the selection of materials by workmen engaged in the work in the shaft with the person who was injured, where they are all working under the same direction.

Riskin v. Iron Cliffs Co., (Michigan) 128 Northwestern, 747. December 1910.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

STAMP-MILLING, A TREATISE ON PRACTICAL STAMP-MILLING AND STAMP-MILL CONSTRUCTION. By Algernon Del Mar. Pp. 134, Ill., index. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$2.

This is a condensed general treatise covering both construction and operation of stamp-mills. The history, principles, and practical workings of stamp-mills are discussed in separate chapters, as also the limitations of single and five-stamp unit batteries, and the process of amalgamation. A long and interesting chapter discusses stamp-mill construction, and in it full place is given to the modern use of concrete in connection with stamp-mills. The illustrations are abundant, and many are excellent, though such as that given on page 73 could be left out to great advantage, as it shows obsolete types of construction, incorrect cam curves, and the ore-bin planking at a different angle from the timbers upon which it is supposed to rest.

The book contains a great deal of information of value to stamp-mill operators, but faulty editing and proof-reading detract greatly from its value. Typographical errors are plentiful. For example: Page 12, third line, "motor" should have been mortar; same page, "Damerest" should have been Demarest. This latter typographical error is repeated on page 5. Page 54, "Columbia" should have been Colombia; page 85, "barral" instead of barrel; page 120, "convas" should have been canvas; page 116, Fig. 85, "bootless" should have been boltless. Page 113 states that Fig. 78 on page 112 shows a two-key tappet. The illustration referred to, however, shows a three-key tappet. The punctuation through the book is so faulty that it is at times difficult even for a man thoroughly familiar with the subject to get Mr. Del Mar's meaning. Many of the sentences and statements are so involved as to be practically meaningless. Page 12, for instance, states that "the amount of ore going through a screen, varies inversely as the square of the size of the openings and so far as I can frame a mathematical law by actually varying the discharge with the other factors constant nearly inversely as the square root of the height of discharge, although the latter factor is influenced by the interior and shape of the mortar."

Differences of opinion make discussion interesting, but few engineers will agree with Mr. Del Mar when he states (page 73) that "the only point in its favor [front-knee battery frame] is that the tight side of the driving belt is uppermost." This is a direct contradiction of one of the elementary principles in the design of horizontal belt or rope drives. We are quite sure that if he will reflect a little he will remember that the lower side of the belt should always be the drive or tight side so that the slack would come at once at the upper side to take advantage of the increased arc of contact and diminish the power losses due to slippage. It is true that the designers of earlier types of front-knee battery frames using the horizontal drive were compelled either to have the tight or drive side of the belt at the top in order to keep the cam-shaft in the boxes, when the boxes were placed at the front of the posts, or else put the cam-shaft at the back of the posts and revolve the cams in the other direction in order to have the lower side of the belt the tight or drive side. Either method has many disadvantages, and the front-knee frame in general is merely interesting from an historical point of view, as it is an obsolete type.

We must frankly confess our disappointment in this book, since Mr. Del Mar's ability as a mill operator is well known, and readers would naturally expect from him a much larger amount of material helpful in daily practice than he has given. This only goes to prove that conspicuous ability in one line does not necessarily mean the same ability in another. Technical writing is an art in itself and the ability to express one's self clearly and fluently in writing is a faculty that requires careful cultivation and training.

CALIFORNIA gold dredges in 1910 produced gold to the value of \$7,550,254, nearly two-fifths of the total for the state. Progress in this great and profitable industry has been due in large measure to the skill and ingenuity of the designers and constructors of dredges, and it gives us pleasure to present in this issue the first of a series of articles, originally contributed by Mr. Robert E. Cranston to the *Journal* of the American Society of Mechanical Engineers, upon the mechanical features and design of the California gold dredge.

DISTRIBUTION of mineral products over the earth's surface exhibits many peculiarities and is a phase of scientific inquiry well worthy of more extended and extensive study than it has yet received. Russia has a natural monopoly of platinum production, for much prospecting has so far failed to discover elsewhere any deposits containing more than small quantities of that metal. Diamonds seem mainly confined to the southern hemisphere of the globe, and tin, while more generally distributed, is curiously limited in its occurrence. Germany possesses the only large deposits of potash salts, while Chile has a natural monopoly of nitrates. Some general features of the causes of so peculiar a distribution are recognized, but much might be learned by a more thorough study of mineral associations.

GOLD and soot both descend on London in large quantities; perhaps the urban dwellers, having the gold, feel they can put up with the soot. Elsewhere in this issue Mr. T. A. Rickard contrasts entertainingly these two striking features of London life, and many of our readers will marvel that Englishmen, usually so jealous of their rights, are content to tolerate the ever-present nuisance of a pall of soft-coal smoke, with its concomitant blinding, choking fog. In New York City the burning of bituminous coal is not even permitted, while in other American cities its use is hedged about with restrictions which provide for practically smokeless combustion. And in California the citizens of a small town have for some years sought to secure the closing of a smelter which is emitting small quantities of SO₂ at a point five miles distant from them. To grope and choke in a London "dreadful" is an experience, for the first time. But London smoke and fog is all so unnecessary, and its persistence is surely an evidence of the moment of inertia of the mass action of humanity.

SYSTEM is the aid by which large quantities of work can be done with the minimum of individual attention, and in these modern days of demand for large output at small cost it is almost universally invoked. System, however, presupposes attention to detail, and we therefore beg to call a minor matter to the attention of our correspondents, whose letters to the editor form one of the most interesting and helpful features of each issue. Such letters are often made by our correspondents a portion of a longer letter, not intended for publication, so that part must needs go to the letter file and part to the composing-room; an

awkward subdivision. If our friends would devote a separate sheet to matter intended for publication, expedition, the co-ordinate of accuracy, would be aided and the editorial staff would be correspondingly grateful.

DISAPPEARANCE of the lines of demarcation which have heretofore separated the various groups dominant in copper mining is an interesting and important feature of present-day finance. Widespread comment has been made upon the various interests represented in the Inspiration Consolidated Copper Company, and other later developments are evidencing a fixed policy in this regard. The flotation of a large copper corporation is impossible, owing to the attitude of the Federal authorities, but control—actual physical and financial control—is not impossible, and apparently this end is to be sought through a degree of co-operation similar to that prevailing in the steel industry. Directorates of the chief companies include one or two representatives of the leading competitors. Recent moves in this direction are seen in the participation of Lake Superior interests in Arizona properties and the placing of a Utah Copper representative on the board of one of the more important developing mines of Butte. A Boston firm which has always been identified with the copper interests centring in and around Duluth has now become interested in the Southwestern Miami Development Company, and Messrs. R. T. McKeever, vice-president of the Copper Range, and Thomas S. Dee, of Paine, Webber & Company, have been elected to the board of the Development company. The second instance is the election of Mr. D. C. Jackling, vice-president and general manager of the Utah Copper Company, to a place on the board of the Butte & Superior Copper Company. Neither move would be particularly significant if taken alone, but as indications of a general drift they may well be considered so.

TOPOGRAPHIC mapping of the United States is not exclusively the province of the United States Geological Survey, as some may suppose, for the survey and mapping of the coasts of the United States and the territories under its jurisdiction is the duty of the Coast and Geodetic Survey, which is under the direction of the Secretary of the Treasury, while the Geological Survey is under the control of the Secretary of the Interior. Though perhaps less well known, the Coast Survey is the older, having begun its work in 1807. In addition to the publication of sailing charts, tide tables, and other aids to navigation it is, with the co-operation of a Boundary Commission, charged with the duty of fixing the boundaries of the United States, and some phases of this part of its work are interestingly described elsewhere in this issue by Mr. O. H. Tittmann, superintendent of the Survey. In the discussion following Mr. Tittmann's address an interesting point was brought out, hinging on the fact that a large part of the boundary between the United States and Canada is designated by international agreement as the forty-ninth parallel of latitude. This seems precise, but as a matter of geophysical fact the axis of rotation of the earth is not fixed, but varies, with a period of about fourteen months, leading to a corresponding variation of latitude, so that if a point upon the boundary is precisely fixed on a given date, and a new point determined with equal precision seven months later the two may be as much as 50 or 60 feet apart on the ground. But if Nature is capricious, man is no less ingenious, and it is worth noting that for the computation of tide tables, prepared in advance for each year, an undertaking formerly requiring an enormous amount of labor by a corps of expert computers, a machine is now being devised which carries out the complicated computations with the infallible precision of a mechanical operation.

TELEGRAPHIC reports from New York indicate that the meeting of the American Institute of Mining Engineers held in that city this week was well attended and harmonious. While proxies had been collected by two different committees, there were no great differences of opinion, everybody showing an earnest disposition to coöperate in any movement for the good of the Institute. The candidates for office as proposed by the nominating committee were all elected, though not by equal votes. The principal difference of opinion was with regard to new members of the Board of Directors, the body which manages the business affairs of the Institute. Messrs. E. B. Kirby, George C. Stone, and Charles F. Rand, nominated by Mr. F. L. Garrison, and seconded by Mr. F. F. Sharpless, were elected. A committee consisting of the new president of the Institute, Mr. J. F. Kemp, and Messrs. C. R. Corning, Albert Ledoux, W. N. Nichols, Jr., and George C. Stone, was appointed to study the affairs of the Institute to determine whether or not economies may be effected in its administration that will remove the necessity for raising the dues. Pending the report of this committee, which is to be made to the Board of Directors not later than June 3, action on the proposed amendments was postponed. This action will commend itself to the judgment of all members of the Institute. If after a full investigation by an independent committee it appears that more income is necessary, we feel sure that the members will gladly vote for the proposed higher dues. If possible, however, rates should be kept low and every effort made to enable the Institute to serve the largest number of men engaged in mining and metallurgy. To the new officers we extend congratulations and good wishes and we feel sure that we voice the sentiments of the entire profession in extending equally hearty good wishes to Mr. Charles Kirchhoff, the retiring president, and the others who have labored with him to make the past year one notable in the history of the Institute. That the year may prove equally significant is the general wish.

Quicksilver

Revision of the chemical tariff is proposed in the bill introduced into the House of Representatives by Mr. O. W. Underwood, representative from Alabama. This tariff affects minerals, ores, and metals, and in previous issues some provisions of the act, which has been passed by the House during the week, and is now before the Senate for consideration, have been commented upon. The bill provides for a general decrease in duties upon mineral substances, and a feature of it which is of much interest to producers in California and Nevada is a provision for a reduction of the duty upon quicksilver from 7 cents per pound to an *ad valorem* duty of 10 per cent. Except as part of a general revision downward there seems to be no good reason for such a reduction of duty, while, on the other hand, there are good reasons against, arising out of the peculiar situation in the quicksilver industry. Most of our readers are aware that in the production of quicksilver the United States does not hold the important position that it does in the production of some other metals. The main supply of this metal comes from Almaden, in Spain; Idria, in Austria; and Monte Amiata, in Italy, the United States production, drawn chiefly from California, serving to meet the demands of the domestic market and supply a small and fluctuating amount for export. The quicksilver mines abroad are under the control of the Rothschilds, while those of the United States are in the hands of independent producers, so that outside the United States a virtual monopoly is enjoyed. Taking the average of producers, quicksilver production is not a very profitable business, the margin between operating cost and selling price being, on the whole,

not a large one. As a result, many producers in America only operate in times of high prices, closing down with a falling market. This operates to steady prices. The protective duty serves in this instance to counteract the lower labor costs of the foreign producer and to protect the American operator against a manipulated market. Decrease of this protection would operate to close down all but the most profitable of the American mines and give the monopoly a free hand. The sum involved is not a great one; the value of the total yearly production of quicksilver in the United States approximates a million dollars, but the principle involved is important. While engaged in 'busting trusts' at home, it is obviously inconsistent to clear the way for a foreign monopoly.

Political Straws

Miners are constitutionally peripatetic, and often spend the larger part of their lives in regions distant from their native land. Separation in space does not involve separation in interest, however, and the most patriotic American is frequently the expatriated one. To all such, the political happenings of the day at home are a topic of intense interest. Their interest often finds too little satisfaction, for, though foreign journals now pay more attention to American affairs, they have not yet completely outgrown the attitude of the days when, as a friend relates, an American, hungering for news of home, at last perceived an item in an European journal and, seizing it, learned that—Josh Billings had had a fit! For such expatriates we will endeavor to sketch some salient features of the preliminaries to the approaching presidential campaign. Our friends at home will pardon us, we hope; the more freely because they know we are tied by no strings and are committed to no policy except to tell the truth, fearlessly, so far as it is vouchsafed us to know the truth.

Among the Democratic forces the search for a leader to conduct them from the minority wilderness is engrossing attention. Mr. Bryan, the doyen of the party, has maintained a non-committal attitude, refusing to make any statement as to whom he would endorse. Among those prominently mentioned are Mr. Judson Harmon, of Ohio, and Mr. O. W. Underwood, of Alabama, while prostituted journalism, as exhibited in the Hearst papers, is lending all its aid to the support of Mr. Champ Clark. Mr. Woodrow Wilson has loomed largest as a possible candidate, and at first showed much strength, but more recently what seems to have been a skillfully engineered attempt to 'do him in the eye' has not been without its effect. Items derogatory to Mr. Wilson managed to gain an astonishing amount of publicity, and finally a letter written by Mr. Wilson in 1907, expressing a not unnatural desire to see Mr. Bryan 'knocked into a cocked hat,' was made public. This seems to have failed of its intended effect of alienating Mr. Bryan's friendship, but injected a certain amount of humor into the situation, and amusement was heightened by the disclosure that Mr. Wilson had begged *Harper's Weekly* to be so good as to cease supporting him, as it was weakening his chances of nomination. Here again friendship does not seem to have suffered materially, but in America it is fatal for a leader to get the public laughing at him, rather than with him, and the indirect effect of all these episodes has undoubtedly served to weaken Mr. Wilson's chances of nomination, and, if nominated, of election. There is no pre-eminent Democratic figure at present, and opportunity bids fair to escape ungrasped, for there can be but little doubt that if the Democratic forces were able to select some strong man and put him early in the field their chances of success in the coming election would be better than at any time in the past fifteen years.

On the Republican side many names have been mentioned. Messrs. Albert J. Beveridge, Hiram Johnson, and A. B. Cummins are suggested by the forces of their respective states, and it is said that Mr. H. S. Hadley, of Missouri, will be urged by his partisans to become a candidate for the nomination. Mr. Robert La Follette was regarded as a strong candidate until, following an intemperate and indiscreet speech before the Periodical Publishers Association on February 2, he was withdrawn, protesting, by his supporters. The impression is general that as a candidate he has destroyed himself, and the choice has now been reduced to Mr. Theodore Roosevelt or Mr. W. H. Taft. Mr. Taft is frankly desirous of reelection, and, like every other president, is in a strong position to dictate his renomination, just as Mr. Roosevelt dictated his nomination in 1908. There can be little doubt that, aside from this advantage, Mr. Taft would have but little chance of renomination, for it is unquestionable that, for one reason or another, his administration has failed from the beginning to command the general confidence of the people in either its sagacity or firmness. In spite of Mr. Roosevelt's declaration that he could not be a candidate for a third term, a strong element in the party seems bent upon slaughtering him, and the governors of a number of important states have declared themselves advocates of his nomination. And why not? Speaking editorially in our issue of March 6, 1909, we said:

"Mr. Roosevelt in his seven or eight years of power has accomplished what otherwise might have required the time of a generation. And this is what the mass of the American people like, having made up their minds that something had to be done to check the corruption that was sapping the foundations of industrial civilization from New York to San Francisco, and from Chicago to New Orleans. He made blunders, but they are deemed well meant; he proved himself a deft politician, but the wires on which he played were occasionally too evident; he was boisterous in his praise of friends as in his condemnation of enemies, but that was considered his breezy way. The public at large took him at his word and liked to see human frailties that brought him closer to themselves. 'He made good'."

Since that time Mr. Roosevelt has traveled widely in European countries and has doubtless benefited by a first-hand acquaintance with other methods of government. Returning to America, he has shown an unexpected degree of self-control in not interfering in governmental affairs, a temptation which Mr. Taft's bungling methods must often have made almost irresistible. His public utterances have been marked by a greater degree of moderation, and his views and methods of action now appear less extreme. If the American people should refuse to allow a convention, created in the early days of escape from monarchical tyranny, to restrict their choice of president, who shall say that they have acted unwisely? At every change of chauffeurs the steering wheel of the automobile is bound to wobble. Unquestionably the change of administration every four years leads to a wobbling throughout the whole industrial machine and, despite the views of the fathers of the republic, it may well be open to question whether we should not do better to get the best chauffeur available and then keep him at the wheel as steadily as possible. In 1797 it may have seemed possible that a great leader might achieve sufficient dominance to make himself dictator or king, but in the year of grace 1911, when even China has become a republic, such a thing is not within the wildest dreams of any crack-brained enthusiast. Beneath an oftentimes almost facetious outlook upon life the American people have a steadiness of purpose and clarity of vision that usually succeeds in obtaining whatever they think they want, at the time. In choosing a president for the next four years this trait will exhibit itself, without a doubt.

Gold and Soot

By T. A. RICKARD

These two products not inaptly typify the energies of the city of London. Taking the more valuable first, I note that the quotation for bar gold remained at its minimum of 77s. 9d. throughout 1911. A price for gold, except in terms of staple commodities, seems strange. As used by bullion-brokers and bankers, it refers to the demand for gold to equalize bank reserves: in effect, the slight difference in the quotation represents the variation in the rate of foreign exchange. Next let us turn to the exports and imports of bar gold. With the figures expressing the latter, my readers are conversant, for they reflect the gold production of the various parts of the British dominions, but the exports give us unfamiliar information concerning the destination of the miner's produce. The figures are given by Samuel Montagu & Co., as follows:

IMPORTS		EXPORTS		PRODUCTION.	
Transvaal	£33,505,000	British India	£7,755,000	Transvaal	£34,991,620
Rhodesia	2,305,000	Germany	5,305,000	Rhodesia	2,647,895
British India	2,250,000	France	4,520,000	British India	2,150,050
South and Central Amer- ican States	1,200,050	Holland	940,000	South and Central Amer- ican States	3,250,000
Australia	1,050,000	Turkey	800,000	Australia	11,882,365
West Africa	940,000	Russia	480,000	West Africa	1,069,442
Natal	670,000	Switzerland	465,000	Natal	Nil
France	575,000	Austria	175,000	France	255,000
Java, etc.	460,000			Java, etc.	480,000
New Zealand	320,000			New Zealand	1,808,049

I have supplied the third column, giving the output in 1911, as this shows how much of it came to London. Obviously London receives practically all of the gold produced in the Transvaal, Rhodesia, West Africa, and British India. No mint exists in any of these regions. Most of the Australian gold is coined at the Sydney and Perth mints; likewise a large part of the New Zealand gold goes to Sydney to be turned into sovereigns and half-sovereigns. The gold credited to Natal must be Transvaal gold that is shipped from the port of Durban, in Natal, for the province of Natal produces no gold. France yields about one-half of the gold imported to London from that country, so that the total represents banking exchange. This is also expressed by exports. In 1911 the international balance was enormously in favor of Great Britain, therefore exports of gold predominated. This was accentuated by the political crisis at Berlin and Paris. In July the Moroccan incident caused Germany to take gold from London, and France to receive gold from New York. British India is a sink for both gold and silver, the natives hoarding them persistently. The Bank of England increased its stock of gold coin and bullion from £30,548,895 at the end of 1910 to £31,732,115 at the end of 1911. The ultimate destination of this metal is indicated by the export of sovereigns.

The world has a great fondness for sovereigns, despite the spread of democratic ideas. The British sovereign passes current without discount, and usually at a premium, in every quarter of the globe. It contains 916.6 gold per 1000 and the rest by law is 'alloy'. In practice this is mostly copper. The silver in old sovereigns is 10 or 15 parts per 1000, but in new coins made from refined gold it is only 1 or 2 parts per thousand. Sovereigns lose in weight, by attrition. On 100,000 sovereigns in circulation the loss is about £20 per annum. This goes to form an ore deposit for posterity. In 1910 the Mint report estimated that in 10 years the circulation of sovereigns increased by £13,000,000. India and Egypt, as well as foreign countries, prefer this form of gold in settling their balance of trade. The Indian Government reported a net importation of 8,162,000 sovereigns and £7,609,000 in bar

gold during the fiscal year 1910-11. Last year the Nile flood was lower, so that, despite the help of the Assouan dam, the cotton crop proved poor; hence £4,000,000 less of gold was required. India, however, benefited from late rains and made a great demand for sovereigns. Indian currency is one of our latter-day problems. According to Samuel Montagu & Co. the import and export of sovereigns in 1911 was as shown in the table below. This last is wholly unlike that previously quoted for bar gold. The exports especially indicate how the less civilized countries require the standard gold coin to 'sweeten' their monetary systems.

From gold we pass to soot. The connection may not be obvious; but it ought to be, for does not carbon precipitate gold from solution, and is not the world's stream

of gold largely precipitated under the black pall of London's sooty fog? It was recently shown by a writer in *The Lancet* that 76,050 tons of soot falls annually over the 117 square miles comprised within the administrative

IMPORTS AND EXPORTS OF SOVEREIGNS, 1911.

IMPORTS		EXPORTS	
France	£1,165,000	South and Central Am. States	£6,430,000
Brazil	1,005,000	Egypt	4,105,000
Egypt	705,000	Turkey	3,480,000
Australia	555,000	France	1,990,000
Switzerland	110,000	British India	1,420,000
		Java and other Dutch colonies..	340,000
		Cape of Good Hope	230,000

area of London. That soot contained many valuable by-products: 8000 tons of sulphates, 6000 tons of ammonia, and 3000 tons of chlorine in chlorides, not to mention the carbon and tar. The rainfall, aided by the sulphuric acid formed from the sulphurous ingredients of the coal burned lavishly and carelessly, has a decidedly corrosive action, as is suggested by the traces of tin and lead found in the soot. However, the chief fact disclosed by these observations is the defective burning of coal within the London area. Faulty combustion and persistent wastage of fuel are indicated. The domestic hearth and the culinary stove are responsible for a part of it; so are the factories; but within the City itself, which is the blackest part of London, the diffusion of soot is due to the obsolete methods retained and repeated in the heating of buildings. I shall not go far afield for an illustration. My desk is in one of the 850 rooms of Salisbury House. This office-building is only a little over ten years old. As the years go in this land of gently shelving precedent, a decade is nothing; to the trustler at San Francisco it is a geological period. Salisbury House is one of the newest of the big buildings

erected for office use in the heart of the financial district, commonly known as 'the City'. It is true the building has only seven stories, a mansard roof, and a basement, but its moderate height of less than one hundred feet marks the maximum permissible under existing regulations. These are embodied in the Building Act of 1894, by which the limit of height for a new building (except by the consent of the London County Council) is 80 feet above the pavement, with two stories in the roof above that height. In the case of a building erected in a street laid out since 1862, the height of a building must not (except with the consent of the County Council) exceed the width of the street. Salisbury House on its main front is 80 ft. high in its central portion, with the two stories in the roof, as allowed by law. The accompanying illustration was lent

amount consumed in 8 hours is that held by a scuttle, namely, 54½ lb. Thus the price is £1 7s. 4d., or nearly \$7½ per ton. The proprietors state that 800 tons of coal, costing them 19s., or \$4.75, is burnt annually. This would indicate that some of the 2500 persons within the building prefer shivering to such measure of discomfort as is obtained from a smoking fire. At a guess, I would say that one-third of the 800 tons escapes up the chimneys and constitutes part of the 75,050 tons of soot that blankets the administrative area of London. A modern heating apparatus, with a furnace in the basement, would save 50% of the fuel, 98% of the soot, and 92% of the coughs and sneezes that harass the denizens of Salisbury House, London Wall, E.C. Joking apart, the method of heating is an excavated anachronism; it involves a waste of coal inversely

SALISBURY HOUSE, OFFICE OF *The Mining Magazine*, AND LONDON OFFICE OF THE *Mining and Scientific Press*.

to me by Davis & Emanuel, the architects of the building, to whom its general appearance and excellent structure, and not its heating arrangements, are to be credited. The structure cost £300,000. The ground rent is £17,000 per annum. This building, which is representative of other supposedly modern structures in London, has no heating apparatus. Incidentally, I may mention that no law exists forbidding the use of such apparatus. The rooms are small, most of them are 12 by 18 ft., and there are 850 of them. Each of these 'dinky' chambers is heated by a small grate, in which inferior coal is incompletely consumed. None of the halls are warmed. Hence the lighting of a fire establishes a draft of cold air from the hall, if the window be shut as carefully as faulty joinery will permit. Long before the room is heated the worker at his desk has been subjected to damp chill. If he does not light his fire early in the morning he receives the smoke from his neighbors, and if he starts this childish heating arrangement late in the day, he finds a reverse draught that fills his room with smoke, and continues to do so until the chimney has been heated. So much for discomfort. Now for rudimentary expense. The tenants pay 8d. or 16c. per diem for the coal they burn. The average

as the square of comfort produced; it illustrates an economic horror: right material in the wrong place. My books and mineral specimens testify eloquently to a persistent deposit of black coal-dust. As I look out of my window I see countless chimneys belching forth unconsumed particles of carbon. I cease to wonder at the spurious antiquity given to stone-work by the blackening hand of time, nor at the swift aging of metal-work by the corroding touch of a sulphurous fog. Nor do I marvel at the sun's eclipse that plunges London into a murky gloom, because the moisture overhanging the Thames valley is given every facility for condensation by the dispersal of myriad particles of foreign matter. Picturesque or not, as a fog may seem to persons of diverse temperament, it spells waste of time and economic loss to the busy people whose traffic and transport are impeded thereby. Not long ago, Sir William Ramsay, a distinguished chemist, but a futile economist, prophesied the exhaustion of England's coal resources within 175 years. His data were incorrect. But the ventilation of the subject should awaken my countrymen to the hideous waste and discomfort incidental to archaic methods of using a great national resource.

Fixing United States Boundaries

By O. H. TITTMANN

*The superintendent of the Coast and Geodetic Survey is commissioner for the demarcation of the Alaskan boundary, and for that portion of the northern boundary of the United States extending from the Pacific Ocean to the Bay of Fundy, with the exception of the boundary running through the Great Lakes. The beginning of the settlement of the boundary, through Passamaquoddy bay, goes back to the Treaty of Peace of 1728; the settlement of disputed questions was again provided for in the Treaty of Ghent, in 1814, but certain portions of the line were not settled until last year. Some portions of the line have never been laid down on any map, but, generally speaking, the duty of the present commission is merely to fix upon the ground, by surveys and monuments, the line where it has not been heretofore fixed with that precision with which boundaries should be marked. The distance from the Pacific Ocean to Passamaquoddy bay, along the boundary, is about 3800 miles, 1200 miles of which are water boundary, running through the Great Lakes. When the boundary to the west of the Lake of the Woods was marked it was supposed that no one would ever feel any particular interest in this unsettled region, and that provisional marks or monuments at long intervals would suffice for all time. Needless to say, the settlement of this country brought with it irritating questions as to the precise location of the boundary line. For the settlement of these questions a joint treaty covering the boundary from end to end was exchanged and ratified, in 1906, although prior to that time an international commission had been at work in a less formal way in restoring old monuments and tracing the boundary where international questions had made it necessary. The triangulation has been extended from the Pacific Ocean to the summit of the Rocky Mountains, and this part of the line has been monumented with aluminum-bronze monuments.

To the east of the Rocky Mountains this same thing has been done, at the present time, to within one hundred miles of the Lake of the Woods, and the whole boundary has been carefully mapped, for a short distance, on each side of the line. Progress has also been made in surveying the thickly wooded region extending from Lake Superior to the Lake of the Woods, and farther to the east the monumenting and surveying is in progress along the northern boundary of Maine. All this work is done by international coöperation, under two commissioners, one representing Great Britain and the other the United States.

Probably more has been said of the demarcation of the Alaskan boundary than of this northern boundary. The determination of the Alaskan boundary has been going on ever since the tribunal, in London, in 1903, settled the vexed question of the location of the southeastern boundary of Alaska. The greater portion of this line runs from mountain peak to mountain peak over inaccessible fields of snow and ice. Starting on the one hundred and forty-first meridian, west of Mount St. Elias, the line follows the summits to the head of Portland Canal, and down that canal to the vicinity of the historic parallel "Fifty-four, forty, or fight," and thence to the Pacific. Wherever it was possible to place monuments it was done, especially at all river crossings in the passes; all of the mountain peaks were trigonometrically located and the region was mapped photo-topographically. From photographs taken at determined trigonometric points maps were made by geometric construction. It is hardly necessary to say that the reports of the surveyors, who conducted this difficult and hazardous enterprise, are full of thrilling adventure, but only two lives have so far been sacrificed. Many of the men had the unpleasant experience of dropping into glacial chasms, from which they were rescued, but the two men who lost their lives fell into an abyss and their bodies were never recovered. The field work of the southeastern Alaskan bound-

dary has been nearly completed. The other part of the Alaskan boundary extends from the vicinity of Mount St. Elias, northward along the one hundred and forty-first meridian to the Arctic Ocean, a distance of about 600 miles. There never has been any international dispute as to that part of the boundary, which was defined by the treaty of 1826 between Great Britain and Russia. But for reasons not necessary to give here a new treaty was made in 1906 by which the commissioners were instructed to determine, by means of the telegraph, a point on the one hundred and forty-first meridian and to trace a north and south line through it, extending from the Arctic Ocean to the southernmost point of this boundary. The physical difficulties of this work are very great, owing to the hardship of transportation and the shortness of the season. The difficulties of transportation are illustrated by the experience of two years ago, when the parties had to march 300 miles to get to the working ground. The plan of the work which is being carried out contemplates a north and south transit line along this meridian, cutting a line through the timber, planting aluminum bronze monuments in rock or cement bases at intervisible intervals, triangulating along the boundary and the topographic mapping of a strip about two miles wide on each side of it. Aside from the immediate purpose of delimitation, this work will serve as an admirable basis for coördinating the land and economic surveys which will follow in another generation or two.

Annual Meeting of the A. I. M. E.

The annual meeting of the American Institute of Mining Engineers was held in the Engineering Societies building, 29 West 39th street, New York, on Monday, Tuesday, and Wednesday of this week. A local committee was in charge of the arrangements for the meeting, which was well attended. The program, as announced was: Monday, February 19—8:15 p.m., informal social meeting at Institute headquarters. Tuesday, February 20—10 a.m., annual business meeting; 12:30 p.m., luncheon at the Engineering Societies building; 2 p.m., technical session; 7 p.m., banquet at Hotel Plaza, 59th street and Fifth avenue. Committee: James Gayley, A. R. Ledoux, D. M. Riordan, Theodore Dwight, and Thomas Robins. Wednesday, February 21—10 a.m., technical session; 12:30 p.m., luncheon at Engineering Societies building; 2 p.m., technical session.

At the business session on Tuesday the following officers were elected:

For President of the Council—James F. Kemp, New York, N. Y. (term expires February 1913), 1262 votes.

For Vice-Presidents of the Council—Benjamin B. Thayer, New York, N. Y.; Karl Eilers, New York, N. Y.; Waldemar Lindgren, Washington, D. C. (term expires February 1914), 1263 votes each.

For Secretary of the Council—Joseph Struthers, New York, N. Y. (term expires February 1913), 377 votes.

For Members of the Council—Joseph W. Richards, South Bethlehem, Pa.; John H. Janeway, Jr., New York, N. Y.; Sidney J. Jennings, Dobbs Ferry, N. Y. (term expires 1915), 1263 votes each.

For Members of the Board of Directors—Edmund B. Kirby, St. Louis, Mo., 1057 votes; George C. Stone, New York, N. Y., 926 votes; Charles F. Rand, New York, N. Y., 926 votes. Arthur S. Dwight, Joseph Struthers, and Arthur L. Walker were also nominated, but did not receive enough votes for election.

On motion by J. Parke Channing a committee, consisting of J. F. Kemp, C. R. Corning, Albert Ledoux, W. N. Nichols, Jr., and George C. Stone, was appointed to study the affairs of the Institute to determine whether the proposed changes in the Constitution of the Institute cannot be obviated by changes in administration. This committee is to report to the Board of Directors not later than June 3, and earlier, if possible. Action upon the proposed amendments was therefore postponed, awaiting the report of the committee. A fuller report of the meeting will appear in a later issue.

*Excerpt from an address delivered before the Philadelphia Engineers Club, November 4, 1911.

Mechanical Features of the California Gold-Dredge—I

By ROBERT E. CRANSTON

*This paper deals only with that branch of gold-dredging which comes directly within the province of mechanical engineering, and the designs described are those commonly used in California. No attempt is made to cover the whole field, and the author has recorded only his personal observations of the more important mechanical features.

In designing a gold-dredge, the first essentials to be determined are the quantity of material to be handled and the depth to which it will be necessary to dig. To a lesser degree, the size and quantity of boulders, quantity of clay, nature and contour of bedrock, contour of the surface, whether the dredge is to be operated in a river or in an inland pond, how high above the water-line it will be necessary to maintain the bank, the nature and consistence of the gravel, distance from a railroad or other cheap transportation, costs of lumber, labor, electric power, supplies, etc., condition of wagon-roads, distance and transportation facilities to a first-class machine-shop, climate, distance to nearest public power-line, and possibilities of developing electric power on or near the property, are important. If electric power is not available, then the costs of the various fuels for generating steam or run-

in its make-up which might be profitably studied by engineers called upon to design similar pieces of machinery.

The first successful gold-dredges in California were patterned after the New Zealand type. A brief description of one of these, built in 1897 and 1898, will not perhaps be out of place. The hull was built of wood of a rectangular cross-section, having an opening or well extending along the centre line part way back from the bow. Near the after end of this well was built an elevated framed

A MODERN 15-FT. DREDGE.

ning gas-engines must be considered, and if the dredge is to be operated inland, how much water is available, and any other data peculiar to the property.

All the above information is requisite for the proper design of a dredge to do the most efficient work. A designer should insist on a full knowledge of all the conditions, otherwise his product is likely to be more or less unsuited to the work it has to do. Beginning with the capacity required, the dimensions of the bucket bases, pins, lips, etc., and the horse-power of the digging motor are determined. The depth of ground determines the length of ladder, which is modified by the height to which it is desired to elevate in order to wash and dispose of the gravel properly. The screen pumps and stacker are designed according to the quantity and quality of coarse material and the height to which it is to be stacked. The other machinery is designed to suit the local conditions, and the hull is planned to support the machinery properly, its dimensions varying greatly from the small capacity shallow diggers, to the 16-ft. dredges excavating 60 or 70 ft. below water-line.

The mechanical equipment of the California gold-dredge as it is today has in it much to be desired in the way of correct dimensions and the relative strengths of its component parts. Many of these parts should be made stronger, likewise there is much waste material which could just as well be done away with. Notwithstanding these admitted faults, the California gold-dredge has during the last few years shown vast improvement over the earlier attempts, and with all its frailties has many good points

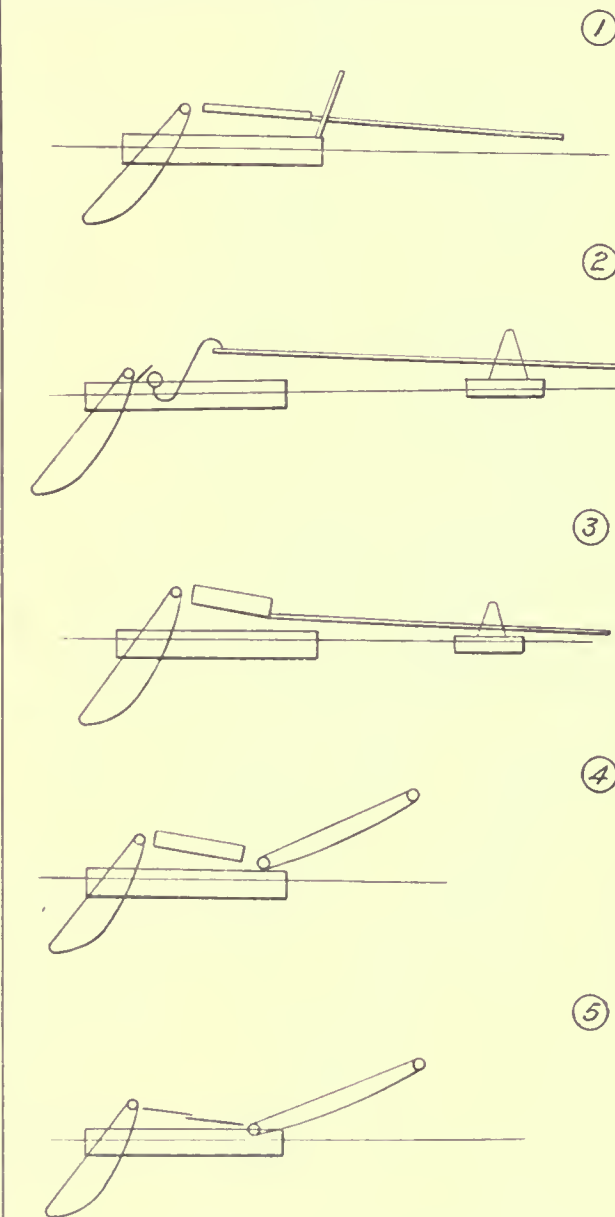

DIAGRAM ILLUSTRATING THE DEVELOPMENT OF THE CALIFORNIA GOLD DREDGE.

structure or main gantry which served to support one end of the digging ladder, the other end being suspended by wire rope blocks from a bow gantry spanning the well. This ladder was a plate girder upon which were mounted rollers to carry the bucket line. The bucket line was composed of alternate links and buckets pinned together to form an endless chain. The buckets passed over a four-sided flanged tumbler keyed to a shaft and driven by a spur gear mounted on the main gantry. At the lower end of the ladder another tumbler served as an idler. In going over the upper tumbler the buckets dumped into a hopper leading into an inclined revolving screen with

*Abstract from the *Journal* of the American Society of Mechanical Engineers.

$\frac{3}{8}$ to $\frac{5}{8}$ -in. perforations. A spray pipe ran lengthwise through the screen, throwing jets of water upon the gravel and washing the finer particles and gold through the screen-holes upon gold-saving tables. These tables were covered with cocoanut matting held in place by expanded metal, and were arranged so as first to distribute the fine material over a considerable area and then discharge it at the stern; the oversize went to a bucket-elevator and was stacked some distance aft of the dredge. The dredge was held up to its work by a head line which could be reeled in by means of a drum on the dredge. Side movement was secured by lines, two at the bow and two at the stern, each running to a separate drum. The motive power for these dredges was steam; later replaced by electricity.

Three years before this type of dredge was introduced into California, one of the type known as the double-lift was built near Bamock, Montana. The main gantry was much lower than in the New Zealand type. A revolving screen was used, but the holes were much larger, so that rocks 4 to 6 in. diameter would pass through. The oversize was dumped at the side of the dredge, and the undersize allowed to collect in a sump, whence it was elevated by means of a centrifugal pump into a sluice running aft from near the throat of the well. At the stern was a pivot connection with another sluice mounted on an auxiliary scow. This scow could be moved from side to side, one end of its sluice being pivoted at the stern of the dredge and the other moving in the arc of a circle, thus distributing the gravel over a considerable area. Instead of a head line, spuds were used to hold the dredge up to its work, the end of the digging-ladder moving in the arc of a circle with the spud as its centre.

About this time several dipper dredges were built, but although some were more or less successful, they did not prove to be as efficient as the endless-chain type, and were soon abandoned. In 1899 a double-lift dredge was built at Oroville, and soon after a similar dredge was built on the American river, the latter, however, being of the single-lift type, using close-connected buckets (every link in the chain being a bucket instead of links and buckets alternating) with spuds, no stacker, but having its main gantry high, the buckets dumping into a revolving screen with large holes. This screen was raised high enough so that the finer material fell directly into a fore-and-aft sluice: the oversize dumped into stone-chutes discharging on both sides of the dredge.

A judicious combination of the best features of the New Zealand and the double and single-lift types described above, together with several new ideas not used in any of the earlier dredges, resulted in a dredge being built sometime in 1901, near Oroville, California, equipped with a shaking instead of a revolving screen, the holes in which were small, the fine material going to gold-saving tables as in the New Zealand type, but with Hungarian riffles replacing the cocoanut matting and expanded metal. The oversize was stacked at the stern by means of a belt-conveyor instead of a bucket-elevator. Spuds and close-connected buckets were used as in the single-lift type. This general arrangement became known as the California type, and with its later modifications is the one to receive the most attention in this paper, and, unless otherwise stated, the descriptions are for this type of dredge.

The original New Zealand type, slightly modified, is still sometimes used for the smaller, shallower, and richer areas, where it is said to do very good work. It is cheaper to build and under certain conditions may prove a better investment than the more expensive California type.

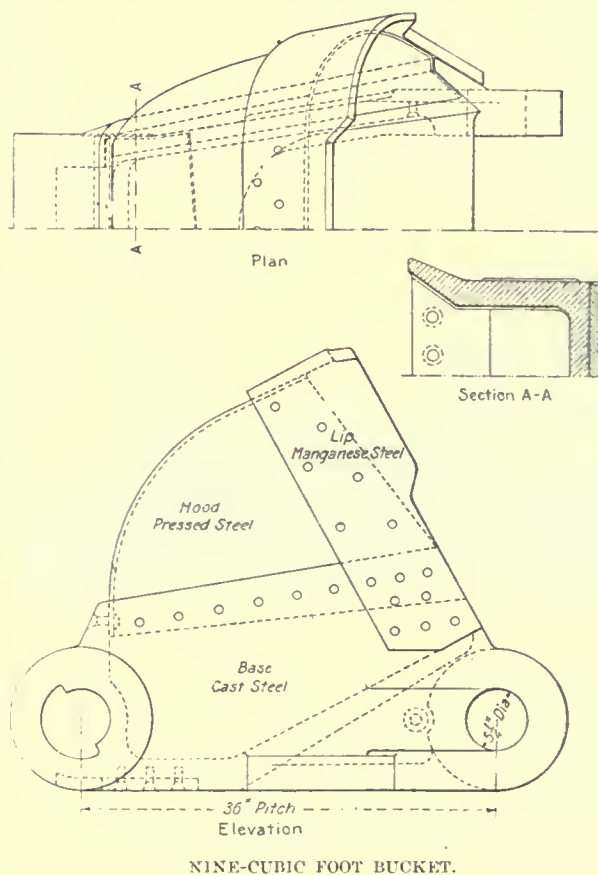

The earlier dredges used buckets holding 3 cu. ft., then the 5-ft. size became numerous, and later the 7, 8, and 9-ft. sizes were much used. Many went back to the revolving screen, noticeably in localities where much clay existed. In 1905 a 13½-ft. dredge was built near Folsom, California, and since that time several with 13½ to 16-ft. buckets have been put in operation. Having gained a general idea of the development of this type of gold-dredge, its different component parts will be taken up in detail.

BUCKET.—The bucket is made up of base, hood, and lip.

The base is made of cast steel, many grades being used. It should be hard so as to stand wear, tough so as to stand the strain of digging, and should not be too expensive, since it has constantly to be replaced when worn or broken. All dredge costs are figured on a basis of cents per cubic yard of gravel handled, so that the first cost is not vital so long as it will handle the requisite number of cubic yards before giving out.

The most common form of base has one hub or back eye fitting between the two front eyes of the bucket behind it. Some use two back and three front eyes. The advantage of the three-eye bucket is that a smaller diameter pin may be used, there being four planes of shear instead of two; the disadvantage is that the cost of machining is greater and there seems to be a tendency to crack these buckets between the two back eyes, owing probably to a prying action under hard digging conditions, particularly after the pins are partly worn.

Besides the ordinary high-carbon open-hearth steel, chrome

nickel and manganese steels are used. One essential is that the bucket casting should be thoroughly annealed before it is machined. It is my opinion that many breaks in bucket bases have been caused solely by improper annealing. A template having long guiding bushed holes is useful in drilling for the hood so that the rivet holes will be accurately spaced both inside and out. This is essential in order that there may be no lost time in making replacements. In machining the base the holes in the eyes should be very carefully bored so as to be exactly parallel with the hole in the hub. In order to do this the bucket may be fitted with its bushing, a shaft put through the hub, the bucket brought tightly against it, and then the eyes bored parallel to this shaft.

Hood.—The bucket hood is made either of pressed steel or cast steel. There are also buckets used which have the hood cast as an integral part of the base. The pressed steel hoods are made in either one or three pieces. The thickness depends on the size of bucket and the nature of the digging, and varies from $\frac{1}{4}$ to $\frac{1}{2}$ in. It is sometimes reinforced at the back where the greatest wear occurs. The cast-steel hoods are usually made about $\frac{3}{4}$ in. thick, have a stiffening rib running up the middle, and sometimes shoulders for the lip to rest on and a shoulder for the base

to fit into. The advantages of pressed over cast-steel hoods are their cheapness, lightness, and ease of repair if bent or broken. A disadvantage is that the strength cannot always be put where wanted except at extra cost. A standard drilled base may be used as a template for drilling the hood. I consider the one-piece preferable to the three-piece hood because (a) it will stay water-tight; and (b) there are fewer rivets to work loose and replace. The disadvantage is the difficulty of pressing a single piece into the proper shape, making the cost greater than if three pieces were used.

Lip.—Bucket lips are now nearly all made of cast manganese steel. At one time I used a very hard high-carbon nickel-steel forging, its only advantage being that it could be shaped on the ground to fit several different hoods and bases which it was desired to use up. A record was kept of about 100 of these lips, and it was found that for cost and life they were very close to the manganese steel. For use in out of the way places and in emergencies they do very well. Their greatest disadvantage is that they cannot be readily forged into the more intricate shapes now commonly used. The lips in use vary considerably in design according to the nature of the ground and the fancy or judgment of the designer. In the first place, a lip must be made strong enough to perform its work without bending or breaking, even up to the time it is ready to be replaced. If it is bent or broken before this time, damage is done the hood, with the resultant extra cost of repairing the hood as well as replacing the lip. The thickness of the lip is determined by the above conditions, but its width is a matter of judgment, since if made too wide the capacity of the bucket is materially reduced by the time it is worn out; if too narrow, it must be replaced often and a large loss results, both in time and unused metal.

Some engineers prefer a highly arched digging face, others a rather flat face with sharply rounded corners. Those favoring the arched face contend with good reason that it is a stronger shape, and those favoring the flat face and rounded corners think that this shape is a better digger. The shape of the digging edge is another matter in which designers differ; some make it perfectly straight, others prefer corner extensions at the points where the wear indicates most of the digging is done. I am in favor of the corner extensions, since I believe they dig better and the lip is more completely worn out when it is ready to be replaced. The fewer rivets used the smaller will be the cost of re-assembling, but care must be taken to have enough rivets to do the work without shearing or pulling out. On many of the lip designs a shoulder is cast so that the hood edge fits against it, thus taking some strain off the rivets.

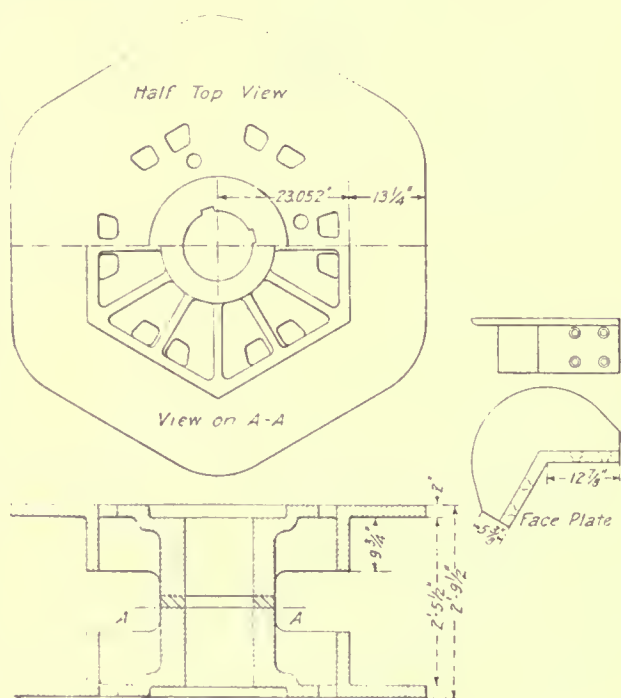

Pin.—There have been many attempts to improve the design of bucket-pins, those ordinarily used being rather expensive to make. It is a round shaft with a flat or 'L' at one end. The L fits into a slot machined in the bucket base and prevents the pin turning in the eyes. Dowel-pins, keys, squared and slotted ends, tee shapes, and many other devices have been tried, but so far as I am aware none of them has proved as satisfactory as the old L design. The pins are made of various kinds of steel, the object being to use a very hard material which is also tough and not too expensive. A high-carbon steel, low in sulphur and phosphorus, forged, machined, and then oil-tempered, is most common. Various forms of nickel, chrome, and manganese steel are also used, but so far have not become general practice.

Bushing.—The bushings are made in pairs, half round, and fit a recess in the bucket hub, placed at such an angle that the wear will be evenly distributed. They should be a snug fit, but $\frac{1}{4}$ to $\frac{1}{2}$ in. short on the ends to allow for the flow of the metal. In using manganese steel this tendency to flow must always be taken into consideration and suitable provision made for it in the dimensions.

Insert Plates.—During the last few years manganese steel insert plates have come into general use in order to protect the bottom of the bucket base near the hub, at which point excessive wear occurs on account of the slip on the upper tumbler. Often buckets are found to be worn out at this point, but perfectly good everywhere else. The manganese

plates are of such a shape that after they are put in place and the softer steel of the base peened over the edges they retain their position without other means of fastening.

LOWER TUMBLER.—At the lower end of the digging ladder the buckets pass over a six-sided flanged tumbler which revolves between forks attached to the digging ladder. It is cast of open-hearth steel. Wearing plates are used to protect the faces and the flanges. The detail of design varies on different dredges. Some use a tumbler having curved extensions at the corners of the flanges, others have the corners rounded but not extended, and still others use a circular flange. The extended corners require less metal, but are likely to be broken off, and the circular flange may interfere with the digging. The design in which a side view will show a hexagonal shape with rounded corners is strong and cannot well interfere with the digging. The height of flange is another point of difference, and varies

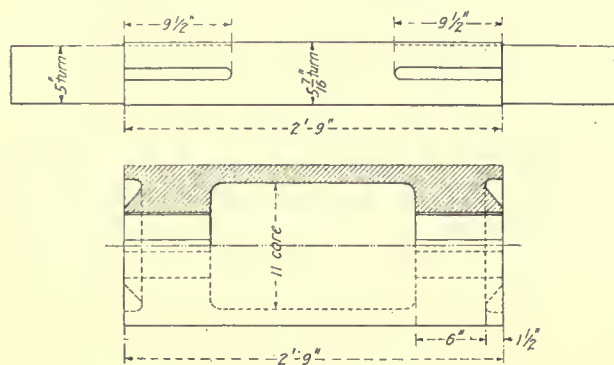

LOWER TUMBLER FOR 9-CU. FT. DREDGE, SHOWING WEARING PLATE.

from 6 to 13 in. at the corners. It must be made high enough to keep the buckets from running off, but if too high may interfere with the digging. It is also expensive. The slope or flare of the flange varies from 0 to 1 in 10. It is claimed by some that if the sides are made too straight the buckets are likely to run off, and if the flare is too great the eyes of the bucket will wear thin at the bottom. I do not know that any standard of flare has been adopted, but I am inclined to the belief that a straight or nearly straight flange is best, all things considered.

Wearing Plates.—The flanges and tumbler faces are protected by wearing plates made of some hard steel; nickel, chrome, and manganese all being used. So far as wearing qualities are concerned the manganese steel gives the best result, but this material is so hard that it cannot be machined, and it is difficult to make the plates fit the tumbler accurately; also, since the rivet holes have to be cored they are likely to be a bad fit. Besides these disadvantages the manganese steel plates are very destructive to the bucket line, and it is better to wear out tumbler plates than buckets. Several tumblers have recently been made with a manganese steel disc set into a recess at each corner and held in place by peening over the edges in a manner similar to the bucket insert plates described above. This method is said to have given good results. Some use separate plates for protecting faces and flanges, while others have the wearing plates made so as to protect both faces and flanges. The advantage of the last method is that the plates are very strong and not likely to break or wear loose.

Shaft.—The lower tumbler shaft is usually made of nickel

steel, either oil-tempered, annealed, or both, and may be hollow bored or solid. It should be securely keyed to the tumbler, and I have found that four taper keys, two at each side, 90 or 120° apart, have given the best results. Provision should be made for driving the keys out from the inside, and the tumbler should be either shrunk or pressed on.

LADDER ROLLER FOR 9-CU. FT. DREDGE.

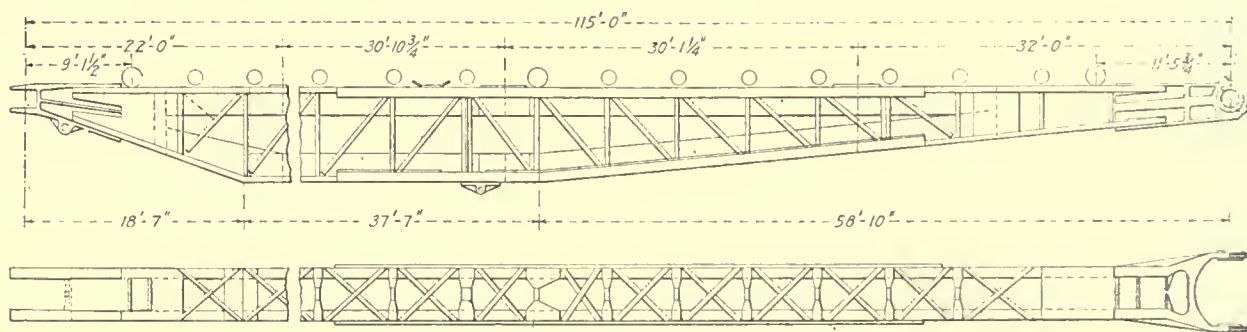

LADDER ROLLER.—The ladder rollers serve to support the buckets on their way from the lower to the upper tumbler. Cast iron was formerly used, but now cast steel, either high-carbon, chrome, or manganese, is most in favor. Very hard chilled white iron cast around a soft core has given good results; also manganese steel made in the same way has

UPPER TUMBLER.—There have been many forms of upper tumbler tried, but now the common practice is to use a 6-sided plain casting, onto which is bolted a set of heavy cushion plates with guides cast on the sides.

Cushion Plates.—These plates are made to lap over the corners and fit into transverse slots in the tumbler casting. This is done to prevent them from becoming loose, as was the case before this design was perfected. They are made of cast steel, either high-carbon, chrome, nickel, or manganese. The cushion plates are bolted to the main tumbler casting by means of large bolts 1 1/2 or 2 in. diam., with square countersunk heads on the outside.

Wearing Plates.—Wearing plates are used on the cushion plates, both for the faces and the guide flanges on the sides. These plates may be made of any material desired, but the same objection to manganese exists on the upper as the lower tumbler. I use plates forged from worn-out bucket pins and then give them an oil temper. These have given good results, but care should be taken not to temper them too hard, since they then become brittle and will give poor service. The wearing plates are riveted with countersunk rivets to the cushion plates. Riveting is better than bolting for this purpose.

Shaft.—It is imperative that the upper tumbler shaft should be of ample strength and be made of excellent material, since it has to bear the brunt of the digging. A factor of safety of not less than 10 is recommended, and it would do no harm to have it even higher. It is customary to use a material of high tensile strength, since if made of

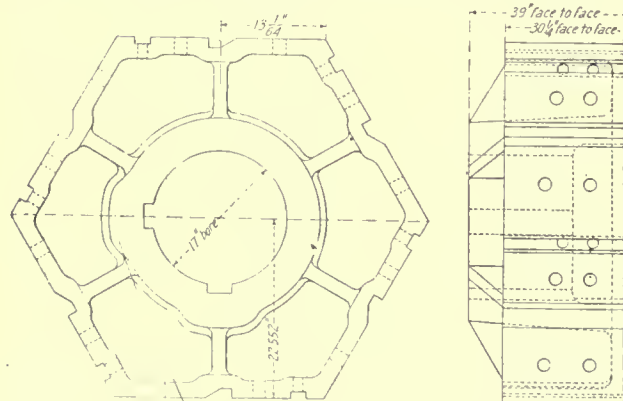

DIGGING LADDER, 9-CU. FT. DREDGE.

proved even more efficient so far as wear is concerned. My objection to the manganese roller is that after considerable use of a soft core, if made thin, is likely to become loose, and if made thick the difference in expansion of the two metals will cause the outside shell to crack. A high-carbon or chrome-steel casting makes a good roller, and

low tensile strength material the shaft will have to be so large that it will interfere with the design of the upper tumbler which it carries. Nickel-steel, hollow-bored, oil-tempered, and annealed shafts are much used, having a tensile strength of 90,000 lb., elastic limit 60,000 lb., elongation 22%, contraction 50%. Excellent results have also been obtained with Krupp crucible-steel shafts, hollow-bored, oil-tempered, and annealed, having a tensile strength of 80,000 lb., elastic limit, 43,000 lb., elongation 22%, contraction 45%. Lately I have used a nickel-steel solid shaft which has been thoroughly annealed but not oil-tempered. This has given excellent results and is inexpensive. The physical properties are as follows: Tensile strength, 80,000 lb.; elastic limit, 50,000 lb.; elongation, 25%; contraction, 45%. A shaft of soft iron or steel, having a low tensile strength but great toughness, such as Lloyds' test steel, would be the ideal shaft for this purpose were it not for the necessity of making them so large that there is no room left to fasten the cushion plates to the upper tumbler. By using a 7 or 8-sided tumbler this could be overcome.

DIGGING LADDER.—The design of the digging ladder varies with the depth and nature of the ground to be handled. It is either a plate girder or a lattice girder or truss. The plate girder type is the most common, and in my opinion the best. A little weight may be saved by using the lattice type, and although it may be as strong as a plate girder, there is in the lattice type more danger of rivets working loose, causing ultimate collapse. Ample space should be allowed under the ladder rollers, otherwise the spill from the buckets will collect and prevent the rollers turning. The ladders are made in several sections so that they may be more easily transported. Where the splices occur great

UPPER TUMBLER, 9-CU. FT. DREDGE.

can be made just soft enough to machine; it will then wear well and need not have a soft iron core. Particularly good results have been secured by me with chrome-steel rollers made in this way.

Shaft.—There has always been trouble in keeping shafts tight in rollers. I use two taper keys at each end, 90° apart, the same as for the lower tumbler shaft. This method of fastening has proved perfectly satisfactory.

care should be taken to make the joints of ample strength. I have seen several digging ladders fail, and in nearly every case the failure occurred at one of the splices. In figuring the strains in a digging ladder it should be considered not only as a beam supported at two or three points, but also as a column. Where a single line is used for side swinging, the strains must be figured for side as well as vertical stress.

Lower Forks.—At the lower end of the ladder cast-steel forks are riveted to the structural portion of the ladder. These forks are made differently by various designers, but their duty in all cases is to carry the lower tumbler bearings and give a space for the lower tumbler to revolve in. These forks should have great lateral strength, since there is a tendency to spread under the severe digging conditions. I have found it of advantage to make the inside edges of these forks fit very closely to the outside of the tumbler, since if a large space is left rocks lodge and grind out both the tumbler and the forks.

Lower Tumbler Bearings.—There are several designs of lower tumbler bearings used. In the most common the lower portion of the forks are made to form one-half of the bearings and to this the other half is bolted. In this design a replaceable cast-iron bushing is made to fit inside the main casting, often of the self-aligning type. I have used a design similar to that of the locomotive connecting-rod end, which is fastened and adjusted by means of taper keys. The bearing is made of cast iron in two halves and slides between the upper and lower extensions of the forks. Square holes are machined through these extensions to take the keys. The half bearings are interchangeable and can be used for the upper or lower half and for either side. This style of bearing has been found very satisfactory, since it is cheap and easily replaced. Many attempts have been made to use protective devices for keeping grit out of the bearings, rubber, felt, brass, and iron rings having been tried. The rubber and felt have been entirely discarded. Some still use bronze or iron protective rings, but they are all more bother and cause more delays than they are worth. A hole through which grease may be introduced is provided at an easily accessible place on the bearings. The grease is introduced by means of a grease gun with a screw-operated piston. I use a lower tumbler shaft with shallow flanges turned at either end. These flanges fit into recesses on the outside of the tumbler bearings, thus preventing the ladder forks from spreading. Where hollow shafts were used it was common practice at one time to put a rod lengthwise through the shaft, a nut at either end preventing the forks from springing apart. With the modern practice of making the lower forks extremely massive there is little danger of springing, and such precaution need not be taken.

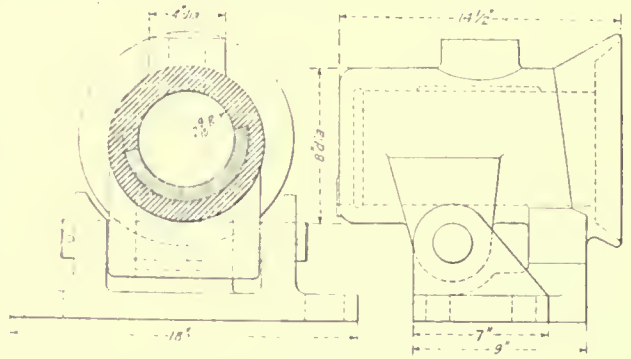

Roller Bearings.—Spaced along the digging ladder at regular intervals are the roller bearings, supported in chairs by pins which allow movement in a plane at right angles to the length of the ladder. The first bearings used were fixed rigidly, and much trouble was experienced by breaking roller shafts, probably caused by movement in the ladder truss. I think it likely, with the heavier ladder construction now in vogue and the larger-sized roller shafts, that the fixed bearing would give little trouble; but even so, the present common design is better, since the bearing may be very quickly and easily removed, and this is a desirable feature in any part of a dredge. The roller bearings are made with half-round bushings similar to those used in the bucket hubs. Cast iron, manganese steel, and bronze are used for this purpose. Cast-iron roller bearings are being replaced by cast steel. Where a self-adjusting bearing is used it should be supported near the middle and be of ample length, otherwise it will tend to tip down and wear out unevenly and rapidly.

Catch-all Pan.—In some of the dredges a pan is provided below the rollers which conveys the slop-over of the buckets to the lower end of the ladder where it will be picked up again. This is a very good idea, but care should be taken to make it at least 12 in. below the rollers and in small, easily replaceable sections. If not deep enough, it is likely to be a source of much annoyance by filling up and stopping the rollers, or if made in long

unprotected sections it will wear out and require much work and loss of time in replacing.

Suspension.—The lower end of the ladder is supported at either one or two points, the single suspension being used for the shorter ladders and the two-point suspension for the longer ones. Several different designs are in use, the most common being a double set of blocks, one on each side, attached to heavy forged rods or bars connecting with the ladder. Heavy chains, forged or cast links and pin links are also used. Another type has a single set of blocks attached to a cross-piece, the connection to the ladder being made from each of its ends. The attachment to the ladder is usually made by means of a cross shaft in bearings fastened to the under side of the ladder.

Upper Forks.—The upper end of the digging ladder is pivoted either on the tumbler-shaft bearing-support or on a separate mounting entirely detached from the bucket drive. By employing the first method the tumbler shaft may be used as a centre, and the relative position of the bucket line and upper tumbler will remain constant for all depths of digging. In the second method the pull on the bucket line will be at different angles, according to the position of the ladder. The first method, therefore, has a decided advantage, but it also possesses the disad-

LADDER ROLLER BEARING, 9-CU. FT. DREDGE.

vantage of preventing the easy removal of the upper tumbler and shaft, is more expensive, and in case of accident to the ladder the bucket-drive may be involved through the tumbler shaft-bearing support.

Chafing Beams.—Along the sides of the ladder wooden chafing beams are bolted, the outer faces of which are protected by steel plates. I prefer beams put at both top and bottom of the ladder, so that they will steady it when digging hard. The beams on the ladder rub against similar ones on the sides of the well. Those in the well are put either at right angles to the ladder at intervals, or one may be placed on each side of the well parallel to the deck and on the streak above water-line. If this form of chafing beam is used, both the ladder and the well beams should have beveled timbers fitted above them, so that rocks will not lodge and cause trouble when the ladder is raised or lowered. The disadvantage of placing the chafing beams at right angles to the ladder is that in case anything catches on one of them near the bottom and tears off a plate, it is very difficult to repair, while if the beams are entirely above the water-line they are easily accessible. The only disadvantage of placing them in this way is that the distance from the contact point of ladder and beam to the ladder's end is greater by the draft of the hull, and in case of side strain the bending moment is greater. Where a shore sheave is used and the end of the swinging line is attached to the lower end of the ladder, there is very little side strain, and in this case the horizontal wearing plates are best, in my opinion. Where a single swinging line is used, running directly to the shore, considerable side strain is exerted on the ladder, and the chafing beams at right angles to the ladder are preferable. Some designers provide rollers for the sides of the ladder, which serve the same purpose as the chafing beams.

(To be Continued)

The Estimation of Tonnage

By A. W. ALLEN

The daily estimation of battery tonnage is a necessity, especially where the manager requires details of approximate yield per ton for the purpose of regulating the output. The choice of a suitable method involves the consideration of existing systems, of which the following will be discussed:

1. By the number of cars trammed to the crushers, or crusher-bins, and an estimated weight of ore content.
2. By the actual weight of the cars and ore trammed to the crushers, or crusher-bins, and a deduction for the weight of the cars.
3. By the number of cars trammed to the battery-bin, after crushing, and an estimated weight of ore content.
4. By the use of an automatically weighing belt-conveyor, discharging into the battery-bin.
5. From the 'running time' and an estimated stamp duty.
6. From the yield in the battery and the difference in assay value of the ore, before and after amalgamation or concentration.

In the first instance, where the tonnage is estimated from the number of cars trammed to the crusher-bin, and an estimated weight, the errors arising may be considerable. The accuracy of the system is influenced by the fact that the cars are seldom uniformly filled, and that the condition of the contents, as to size and composition, is liable to vary within wide limits. It is almost impossible to estimate the moisture content with any degree of accuracy, or to obtain a truthful average. An advantage is gained by the direct weighing of the cars and the automatic recording of results. In the latter case the moisture is the only consideration affecting the accuracy of the result.

After the ore has passed the grizzlies and crushers it is in better condition for the purpose of tonnage calculation; but an estimation based on the number of cars trammed is again influenced by the way the cars are filled and the degree of moisture in the contents. The latter determination is now an easier matter, but the result is liable to be affected by systematic under or over-filling of the cars, and any carelessness in recording the number. These latter defects can be remedied by the substitution of an automatic weighing, recording, and distributing belt-conveyor in place of the cars; and the degree of accuracy in the result is then only affected by the accuracy of the machine, and the correctness of the moisture deduction.

The determination of moisture content is an important matter, but receives scant attention in the battery. Even after crushing and automatic weighing, an estimation is no easy matter, since *average* moisture content implies the drying of an *average* sample; and the time taken to obtain such a sample would influence the result, unless impracticable precautions were taken to prevent moisture loss. In the few cases where ore milled is quite uniform, a 'grab' sample might contain an average moisture percentage. Contrary conditions, however, predominate; and sometimes it is necessary to consider the effect of tropical rain on alternate cars of clean quartz and old stope fillings, on their way to the mill. In the latter case even an automatic record of actual weight would be exceedingly difficult to correct for moisture content.

All the methods discussed give approximations of tonnage delivered into the crusher or battery-bin, and not tonnage milled. To make daily correction, involving the estimation of what remains in the battery-bin, or both battery-bin and crusher-bin, reduces the estimate, in the majority of cases, to mere guesswork. A monthly estimate would, doubtless, be more correct, since the error liable to arise on the question of storage, would be minimized; but a daily estimation is under consideration. Tonnage totals cannot be added to or subtracted from as the need for correction becomes apparent. At the end of the month the figures must be either taken or rejected as a basis for the com-

pilation of cost, extraction, and other returns.

The daily estimation of tonnage by means of a calculation based upon the 'running time' and estimated stamp duty is at best a loose method, because 'stamp duty' is known to vary considerably and is affected by a number of circumstances which cannot be taken into account in the calculation. In a 200-ton, 50-stamp mill, recovering 30 oz. of silver per ton, and assuming accurate sampling and assaying, a difference of but one-fifth of a ton per stamp per 24 hours between actual and estimated duty would, at the end of a month, mean a difference of no less than 9000 oz. between actual and calculated returns. The busy millman may also be excused if 'running time' is not always reported in exact figures. This method of calculation has, however, much to recommend it, because no estimation of ore in hand, or moisture content, is needed; but, in the same manner as the results by other methods are affected by variable moisture content, due to lack of uniformity in the product, so is stamp duty liable to fluctuate from the same cause. On the other hand, there are a number of cases where stamp duty remains remarkably uniform, and where this method of calculation is indicated as the best available.

Method No. 6 is, I believe, still in use; and details may serve to prevent further adoption. By this method tonnage is calculated by means of the actual yield in the battery, and the assay of the ore before and after amalgamation or concentration. The figures are bound to tally because the artificial manipulation of results adjusts all possible variations between assay difference and actual returns. The method is only applicable where yield and value are obtainable daily; as, for example, where the concentrate produced is dried, weighed, sampled, and assayed every 24 hours. Given correct sampling and assaying, and the absence of theft or loss in the yield, the result is accurate. On the other hand, with a milled ore yielding high-grade slime and low-grade sand, the extraction figure can be raised at will by the exclusion of a proportion of slime from the tail sample; a drop in stamp duty taking the place of a discrepancy in realization. Theft or mechanical loss would, if undetected, also result in a lower tonnage estimation. In any case, the extraction figures would always agree, and, for this reason and because the method is open to abuse, the system is not to be recommended.

From the above considerations it will be seen that, in the absence of consistent uniformity, the correct statement of battery tonnage is a result more of accident than design; and ordinary estimations, although useful for the determination of daily yield per ton in the battery, are valueless for the purpose required in a detailed return showing actual and theoretical extraction. I therefore suggest the daily use of battery estimations for the purpose outlined, but the compilation of extraction and other returns based on figures obtained where the tonnage of individual lots of ore can be checked and re-checked should occasion arise. This is only possible in the cyanide plant where ore units are, generally, of easily defined volume, of uniform composition, and of uniform moisture content.

In leaching-vats, filled by means of automatic distributors and the adjustment of slats, the tonnage is best calculated by the aid of a box with perforated sides and rope handles, of exactly one cubic foot capacity. The perforations in the sides are important and allow the escape of slime as the box fills with sand, uniformly with the vat. As soon as covered the box is pulled up, the contents leveled off and allowed to drain. The box and contents are then weighed, by means of a steel-yard or spring balance. The sand is then tipped out and a moisture sample sent away for immediate estimation. A deduction for the weight of the box is made and the tonnage in the vat finally calculated from the dry weight of the cubic foot of sand, and the cubic contents of the vat. The result can be verified by alternate weighings.

The tonnage in an agitation-vat is generally deduced by methods involving estimations of the specific gravity of both ore and pulp. Published formulae, complicated by the addition of constants and factors dear to the mathematician but abhorrent to the operator, are generally without explanations; and entire reliance on such formulae too often results in mental lassitude and lack of initiative. The correct estimation of ore tonnage in pulp is a much easier matter than is generally supposed; and, if a simple line of reasoning be adopted, the matter of a lost or forgotten formula is of no consequence. The following details may be of use to the working operator who wishes to take an intelligent interest in the method.

The specific gravity of a substance is an amount equal to its weight divided by its volume. Conversely, the volume of a substance is an amount equal to its weight divided by its specific gravity; or is the volume of water it displaces when submerged. Advantage is taken of the latter fact in the preliminary estimation of the specific gravity of the slimed ore, the following method usually being adopted. A suitable flask is taken to which is transferred a portion of slimed ore pulp. The flask is then filled to a mark with water, and weighed. The contents are next discharged, any residue remaining washed out, and the whole carefully dried and weighed. Then if

A be the weight of the dry slimed ore,

B be the weight of flask, slimed ore, and water to mark, and

C be the weight of flask and water to mark,

$$\begin{aligned} \text{the sp. gr. of the ore} &= \frac{\text{Wt. of slimed ore}}{\text{Wt. of water it displaces}} \\ &= \frac{A}{(C + A) - B} \end{aligned}$$

The result should be carefully checked and the fact remembered that an overestimation of the specific gravity of the ore results, by subsequent calculation, is an underestimation of tonnage; and vice versa.

The specific gravity of the ore pulp in agitation is found in the following way. A fairly wide-mouthed flask or bottle, of known capacity, is taken, filled with the pulp, and weighed. The net weight of the pulp, divided by the volume occupied, will give the specific gravity of the pulp. If a special weight is used to counterbalance the weight of the empty flask, and the capacity of the latter is one litre, the specific gravity of the pulp can be found by direct weighing, and with no more calculation than the placing of a decimal point, thus:

Capacity of flask.....	1000 c.c.
Wt. of 1 litre of pulp.....	1330 gm.
Sp. gr. of pulp.....	1.33

The following line of reasoning may be adopted for the calculation of the percentage of slime, in terms of dry ore, in the pulp:

Vol. of pulp = vol. of ore + vol. of water.

$$\begin{aligned} \text{If } a &= \text{wt. of pulp, then, } \frac{a}{g_1} = \frac{x}{g_2} + \frac{y}{g_3} \\ g_1 &= \text{sp. gr. of pulp, } \frac{a}{g_1} = \frac{x}{g_2} + \frac{y}{g_3} \\ x &= \text{wt. of ore, } \frac{100}{g_1} = \frac{x}{g_2} + \frac{100 - x}{g_3} \\ g_2 &= \text{sp. gr. of ore, } \frac{100}{g_1} = \frac{x}{g_2} + \frac{100 - x}{g_3} \\ y &= \text{wt. of water, } \frac{100}{g_1} = \frac{x}{g_2} + \frac{100 - x}{g_3} \\ g_3 &= \text{sp. gr. of water, } \frac{100}{g_1} = \frac{x}{g_2} + \frac{100 - x}{g_3} \\ 100g_2 &= xg_1 + 100g_1g_2 - xg_1g_2 \\ xg_1g_2 - xg_1 &= 100g_1g_2 - 100g_2 \\ x(g_1g_2 - g_1) &= 100g_2(g_1 - 1) \\ x &= \frac{100g_2(g_1 - 1)}{g_1(g_2 - 1)} = \text{\% ore in pulp.} \end{aligned}$$

Given the weight of a cubic foot of water as 62.5 lb., the specific gravity of the pulp, and the capacity of the vat in cubic feet, the estimation of ore content can readily be found by the aid of the calculated percentage of solids. Unnecessary calculations are avoided by filling the agitation vats to the same level, and by the compilation of a table based on the capacity of the vat to this level; and arranged to show, at a glance, the tonnage contained for any average specific gravity of pulp.

Tonnage estimations should be made with the greatest care where the amounts are to be used in conjunction with assay returns. The net weight of ore taken for specific gravity purposes should not be much less than 500 gm.; and weighings should be made on a balance sensitive to 0.5 gm. or under. In specific gravity estimations of the ore, and moisture determinations generally, repeated dryings should be made to demonstrate the absence of residual moisture, the sample being cooled in a desiccator before being weighed.

Preservative Treatment of Poles

By W. H. KEMPFER

As the pressure method of treatment with creosote is comparatively costly, investigations by the Forest Service were directed to simpler and cheaper methods, which could be employed locally. Special attention was given to the seasoning of the timber, and investigations were conducted with the object of (1) testing the efficiency of various wood preservatives and of the application of varying amounts; (2) developing a method for impregnating the butt, as the portion of the pole most subject to decay; (3) designing inexpensive apparatus for local use in application. The timbers used were chestnut, three kinds of cedar, and three kinds of pine; and six different commercial preservatives were tried. The conclusions reached were: The reduction in the weight of poles by seasoning is generally from 16 to 30%, and thorough seasoning is an essential preliminary to preservative treatment. Poles cut during autumn and winter lose weight less rapidly but more regularly than those cut during the spring and summer; the shrinkage during seasoning does not exceed 1% of the circumference; too rapid seasoning may be detrimental to the timber by causing excessive 'checking.' The superficial application of a preservative, by a brush, to the butt of a pole is not as effective as actual impregnation of the wood, but generally adds two or three years to the life of the pole. Impregnation of many pole timbers may be successfully accomplished by simple immersion in open tanks, first in the hot and then in the cold preservative; as this process may be applied to the butts only, a great saving of preservative is effected.

Sulphur Mines in Mexico

By Wilbert L. Bonney

The great bulk of Mexican sulphur is obtained from the mines near Cerritos, in the state of San Luis Potosi, about fifty miles east of the capital. The deposit is one of the largest and richest in the world. The production of the mines is about 800 metric tons (metric ton = 2204.6 lb.) of refined sulphur per month. The sulphur is found at a depth of 20 ft. below the surface, and the lowest present workings are 190 ft. deep. The mines are at an elevation of about 5800 ft. above sea-level. The ore runs 37 to 90% pure and is melted by the steaming process. Of this product about one-third finds a market in Mexico, the present price being around \$32 per metric ton. The mines employ some 700 men. The property is owned by the Virginia-Carolina Chemical Co., an American concern, but is under lease to Germans. The excess over home-market demands is shipped to Germany.

There are traces of sulphur in other parts of the state, and compounds are common. At Venado, about fifty miles north of San Luis Potosi, a sulphur deposit has been uncovered, but its output would be small compared with the Cerritos mines. The Venado deposit lies in a blanket some 10 ft. wide practically on the surface, and the product shows about 30% pure sulphur. The operating company had its furnaces installed by an Italian expert after the manner of the Italian smelting practice, but the capacity of the works will not exceed three to four tons per day under favorable circumstances. *Daily Consular and Trade Reports.*

The Largest Single-Unit Crushing Plant

By SAMUEL W. TRAYLOR

*This crushing plant, which is at Valhalla, in the suburbs of White Plains, New York, is in process of construction for H. S. Kerbaugh, Inc., and is to be used by this company to prepare stone for concrete to be used in the erection of the Kensico dam, contract No. 9, Board of Water Supply, City of New York. The great size of this work calls for and warrants the use of so large a plant. This dam, which is being built across the bed of old Lake Kensico at about 400 ft. north of the old impounding dike, is to be used as a storage reservoir in connection with the new Catskill system, and will retain sufficient water behind it to insure a supply of about 45 days to New York City, in case of an accident to the system between Lake Kensico and Ashokan. The dam itself is to be built of cyclopean masonry, faced on its upstream side with concrete blocks and on its downstream side with cut stone, and will contain over 1,000,000 cu. yd. of masonry, thus making it take rank as the largest masonry dam in the world.

The geological structure of the valley, which at the point of the dam is 1900 ft. wide, is rather peculiar, it being eroded out of a bed of dolomite, about 400 ft. thick, which lies between the gneiss of the easterly hill and the mica schist of the westerly hill, and at the point of contact there is the badly decomposed and disintegrated condition of the rock naturally to be expected. This will make necessary an excavation of about 130 ft. below the present surface of the valley to insure a dependable foundation, and at this point the total height of the dam will be about 300 ft. The general design of this dam follows the lines adopted in the design of the Ashokan dam, incorporating the peculiar features of expansion joints, drainage wells, and galleries adopted there. The section is of peculiar interest at the present time, when the matter of gravity dam sections is uppermost in the public mind, because of its stability, as the extreme width of this dam will be about 250 feet.

Quarry Equipment.—The pneumatic drills used in quarrying are the largest made for this purpose, having a capacity for boring a 5-in. hole to a depth of 20 ft. There will be used four 90-ton, 4-yd. steam-shovels in loading the rock into the quarry cars. The transportation facilities consist of four 40-ton locomotives, each handling a train of 15 to 20 cars, each car having a capacity of 8 yd. As the trains are loaded, they are hauled into the crushing plant, where the cars are quickly dumped by an ingenious device, and the rock discharged into a chute leading directly to the initial crusher. The train is then hauled through the crusher building and returned to the quarry over a separate track.

The initial 5 by 7-ft. crusher reduces the rock to a size of 9 in. and smaller. It then passes over a grizzly with 4½-in. opening, the undersize or through product going directly to the elevator, while the oversize is run through the second crusher, with an opening 3 by 6 ft., reducing it to 4 in. and smaller. This product, with the undersize from the grizzly then goes to the elevator and is raised to a 7 by 30-ft. screen. This screen is so designed that all material ¼ in. and finer is removed for a sand product and stored separately, while the aggregate, or stone between ¼ and 2½ in. is distributed by a 30-in. conveyor into a 10,000-ton storage bin. The oversize from the screen goes to a small bin, which is equipped with a 28-in. steel pan-feeder and is delivered uniformly to a heavy duty 30 by 60-in. crushing roll; the product from this roll being returned to the same elevator and screen.

The storage bins are so constructed with bottom and side discharge gates as to permit of loading standard-gauge cars running under the bins as well as at the sides, preventing any congestion at this point and making available the full

storage capacity of the bins by reason of the many points from which the product is discharged.

General Plan.—From this brief description, and reference to the side elevation, the simplicity of design and economy in operation will be noted, as well as the small number of individual machines required for so large a capacity. Brief specifications are as follows: 1 jaw-crusher, with a clear opening of 5 by 7 ft.; 1 jaw-crusher, with an opening of 3 by 6 ft.; 1 continuous bucket elevator, with buckets 42 in. wide by 18 in. deep by 19-in. projection; 1 all steel 7 by 30-ft. revolving screen; and 1 30 by 60-in. heavy-duty crushing roll.¹

It will be seen that this plant presents interesting features, from the fact that to duplicate its capacity would require not less than nine gyratories, and if a No. 21 gyratory were used as the initial crusher, all rock coming from the quarry would need to be broken to a size of 3 ft. or smaller before it would enter the crusher. The necessity of breaking the quarry product to 3 ft. and smaller would add materially to the cost of operation of a gyratory plant. The initial crusher in the plant as built, however, will take any piece of rock that will ordinarily come from the quarry, and this greatly reduces the cost of quarrying, handling, and crushing. The matter of repairs is of small moment in this plant, as it is estimated that all wearing parts will last for two years or more in continuous operation without renewals.

Some of the novel features of this plant are the trackage arrangements and the facilities for loading and unloading all products during construction, there being provided a standard-gauge track along the upper side of the plant; a crane runs over this track and into the crusher building, facilitating the removal and placing of the heavy machinery directly from the railroad cars. When the plant is completed this same track will be used for returning the empty cars to the quarry. The crane is so placed that it may be used to advantage, if necessary, for removing pieces of rock more than 7 ft. in size which may have gotten into the plant by accident, and any possibility of congestion from this source is avoided.

There are also two main delivery tracks running directly through the building, and heavy chutes extending from both tracks to the initial crusher. Only one of these tracks will be used at a time, the other being purely an auxiliary to be used in case of mishap or obstruction, when it may be put into commission, thereby making it unnecessary to close down the plant. This track equipment is so arranged, also, that the initial crusher can be temporarily closed down and the rock fed directly to the second crusher, this being especially desirable should the rock from the quarry be running in small sizes, such as would enter the second crusher without difficulty, thus not only saving the large crusher, but considerable expense in the matter of power. This arrangement also permits the making of repairs or changing of wearing parts on one machine without the necessity of closing down the whole plant.

Unloading Device.—There is provided a special unloading device which is supported by the crane extending over the large crusher, delivery tracks, and chutes. This device consists of an air-lift, the cylinder being 20 in. diam., designed to work under an air-pressure of 80 lb., and having a lifting capacity of ten tons. As the cars pass in front of the chutes, one man can quickly dump them by hoisting one side of the car; a very economical arrangement.

Large Crusher.—The large or initial crusher in this plant has a jaw opening of 5 by 7 ft., and will easily take a stone weighing 10 tons and reduce it within one minute. This crusher is constructed of cast steel throughout, with the exception of the large fly-wheels, and has a total weight of 450,000 lb. The fly-wheels are 12 ft. diam. and weigh 15 tons each. The swing-jaw shaft is 20 in. diam. and weighs 6 tons, while the pitman shaft is 24 in. diam. in the pitman and 20 in. at the bearings, and weighs 8½ tons. The swing-

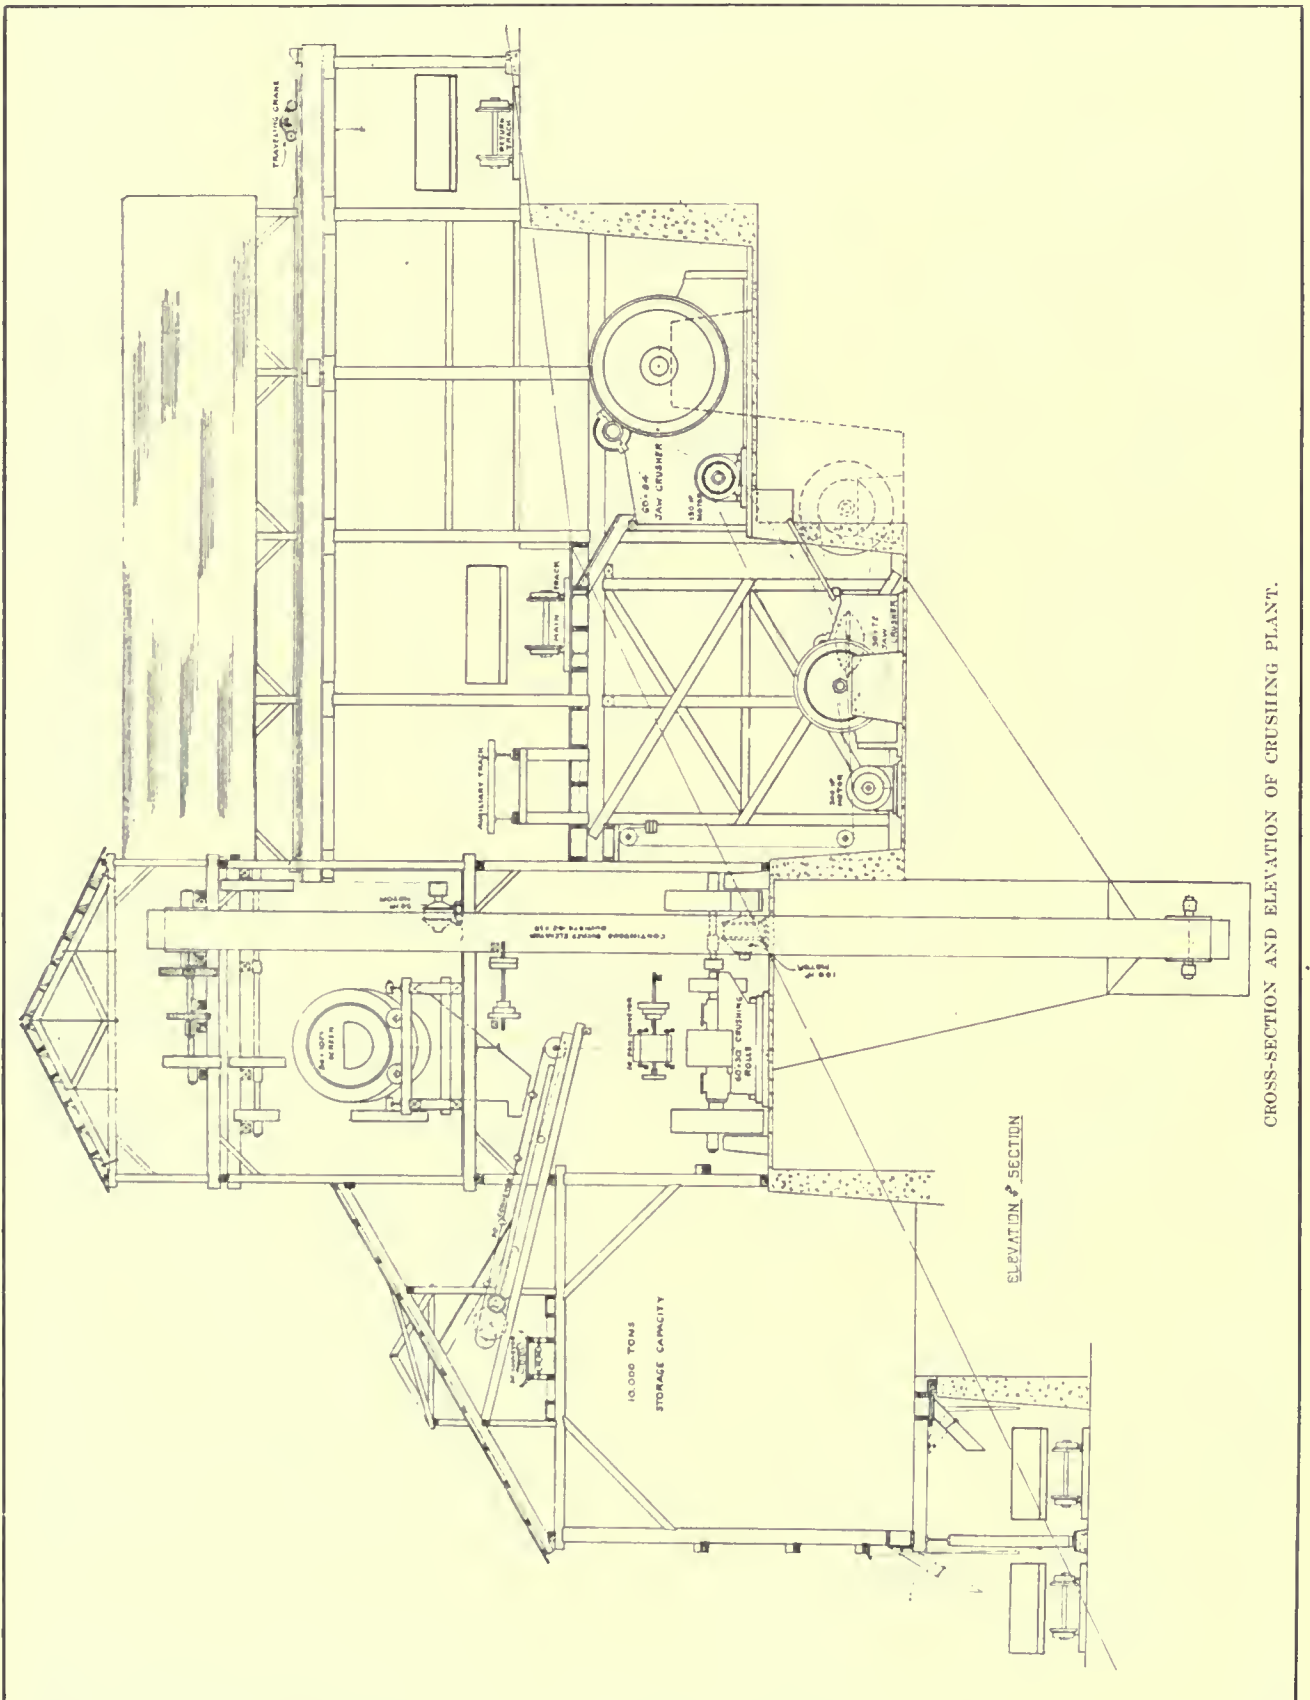

*By courtesy of the author, we are enabled to present this description simultaneously with its publication in *Engineering News*.

¹The crushing plant was designed by the Traylor Engineering & Manufacturing Co., 30 Church street, New York, with works at Allentown, Pennsylvania, and is being erected by them, including all buildings and the setting of the machinery.

ing jaw of this machine is 13 ft. long by 7 ft. wide, and weighs 74,000 pounds. The wearing plates are made entirely of manganese steel in sections which are interchangeable, so that the different sections may be changed about from time to time, thereby greatly increasing their life. All bearings are water cooled, and compression grease cups 12

swing-jaw shaft is 12 in. diam., and the pitman shaft 14 in. at the pitman and 12 in. at the bearings. The fly-wheels are 8 ft. diam. by 12-in. face, and have a peripheral speed of 5000 ft. per minute, being operated at a speed of 200 r.p.m. The total weight of this machine is 210,000 pounds.

Elevator.—The situation of the plant is such that it re-

in. diam. are provided as an integral part of such bearings for lubrication. The over-all length of the crusher is 24 ft., the width 15 ft., and the height 13 feet.

Second Crusher.—The second crusher has an opening of 3 by 6 ft. and is of the same type as the large one, with an over-all length of 13 ft., width 13 ft., and height 9 ft. The

quires the raising of all product, after passing the second crusher, to the screen. The elevator used is of the continuous type, each bucket being 42 in. long, 18 in. deep, and 19 inches in projection. These buckets are fastened to a shaft, the ends of which are equipped with steel-bushed rollers. These rollers travel on a 30-lb. rail made fast to

runway timbers. Each bucket is provided with a double link-bar on each side, made of $\frac{1}{2}$ by 3 by 18-in. bars. The rollers are lubricated by means of compression grease-cups suitably connected to the end of the roller shaft. The buckets are made of $\frac{1}{4}$ -in. steel pressed from a single sheet and reinforced with a $\frac{3}{4}$ by 2-in. bar strap fastened on the lip of the bucket, for taking the wear at this point. The speed of the elevator is 95 ft. per minute. The head of the elevator is equipped with compound back gears of large dimensions and operated from the line-shaft that drives the screen.

Rolls.—The 30 by 60-in. heavy-duty roll is one of the largest smooth-faced rolls yet built in this country, considering the width of face and weight of machine. This roll has an over-all dimension of 16 ft. The shafts are 16 in. at the hub and 14 in. at the bearings, each bearing having a length of 46 in. The frame is cast in one piece, and alone weighs 30 tons. The drive pulleys are made of cast steel, the main pulley being 96-in. diam. by 24-in. face, while the smaller pulley on the movable roll is 60-in. diam. by 14-in. face. This roll is operated at a speed of 50 r.p.m. or a peripheral speed of 785 ft. per minute. The rolls are equipped with an ingenious lateral adjusting device to prevent corrugating or channeling of the roll tires. The bearing of this roll is so constructed that it is double the size required for the work being done, is dust proof, and is efficiently lubricated. Its capacity is 300 yd. per hour, crushing from 4 in. down to 2 inches.

Power.—The large crusher is operated by a 300-hp. 3-bearing form 'M' mill-type induction motor, of the slip-ring type, and has about $2\frac{1}{2}$ times full torque load in starting. It operates at a speed of 560 r.p.m. This motor is equipped with a self-starting regulator, 27 by 33-in. pulley, and drives a jack-shaft with a 26-in. triple-leather, endless belt, the pulley on this shaft being 27 by 94 in. This jack-shaft is equipped with an approved individual friction cut-off clutch which permits the starting of the crusher after the motor is in motion. On this jack-shaft is a 60-in. heavy sheave wheel, with 15 grooves for $1\frac{1}{2}$ -in. rope, by which the large crusher is operated, the driving sheave on the crusher shaft being 11 ft. diam. A suitable tension carriage and idler sheave is used in connection with this rope drive.

It will be noted that on account of the intermittent load, due to the irregularity in the size of product fed into a crusher of this size, it becomes necessary to have great flexibility in the transmission, although it is apparent that when this crusher is operated at full speed, with the enormous momentum of the two 12-ft. 15-ton fly-wheels revolving at a peripheral speed of 3400 ft. per minute, there can be but little variation, even though the feed is intermittent.

The motor for operating the 3 by 6-ft. crusher is 150 hp., 560 r.p.m., and of the same type as the 300-hp. motor above mentioned. It is equipped with self-starting regulator, and a pulley 21 by 29 in. is belted direct to the crusher, with a 20-in. extra double-leather endless belt. The crushing roll is operated by a 100-hp. 560-r.p.m. motor, of the same type as the others, and is equipped with a pulley 17 by 21 in., which drives a 17 by 108-in. pulley on a jack-shaft, this jack-shaft operating the rolls and also the countershaft that drives the roll feeder. The elevator and screen are driven by a separate 50-hp. type 'K' squirrel-cage induction motor, equipped with self-starting regulator, and operates at a speed of 850 r.p.m. There are two conveyors in the plant—one, the short or cross-conveyor, is operated by an individual 5-hp. type 'K' motor, direct connected through gearing and countershaft; the other, or main conveyor, is driven by a 15-hp. type 'K' motor, direct connected through gearing and operating at a speed of 850 r.p.m., and provided with an individual automatic starter. The current used is alternating, 3-phase, 60-cycle, 440 volts, stepped down from 2200 volts.

THE production of manganese ore in India increased from 642,675 tons, valued at \$1,819,540, in 1909, to 800,907 tons, valued at \$1,145,275, in 1910. The principal mining of manganese ore during the year was done in the Central Provinces.

California Gas Production

The report of the United States Geological Survey shows an increase in the production of gas in California in 1910, as compared with previous years, and the probability is that this increase will continue on account of the new discoveries recently made. In the Midway district of Kern county four gas wells of high pressure and large capacity had been completed at the close of 1910, and although the gas from these wells was used to some extent for field purposes, preparations were in progress to pipe the gas to towns in the neighborhood of the wells. It is reported that Bakersfield and Fellows are to be supplied, and Taft and Maricopa are now being supplied. Many of the oil wells in California produce sufficient gas to operate the wells, and some have gas to supply neighboring leases both for drilling and operating, as well as to supply a few domestic consumers in the vicinity of the wells. Early in 1910 the exploration for oil to the east of the South Midway fields developed some unusually large gas wells in the Buena Vista hills. Near the close of the year these wells were gotten under control, and active steps were taken for piping the gas to Bakersville. There is every indication that gas will be eventually piped down the San Joaquin to Fresno, and thence to San Francisco in one direction and to Los Angeles in the other. The total production of gas in California was estimated at 2,764,507,000 cu. ft. in 1910, valued at \$476,697, of which 245,738,000 cu. ft., valued at \$194,631, was supplied to domestic consumers, and 2,518,769,000 cu. ft., valued at \$282,066, was supplied to industrial consumers. The gas supplied for industrial purposes was chiefly the product of the oil wells and was utilized for drilling and pumping in the field. The number of gas wells in California at the close of 1910 was 55, three gas wells having been drilled during the year. The number of gas wells abandoned in 1910 was twelve.

MANY attempts have been made to introduce paper as a substitute for the costly prepared skins used by goldbeaters, but only with partial success. Paper was employed before goldbeaters' skin for making leaf metals, and the Chinese and Japanese still use paper, made from the fibres of the mulberry tree, for goldbeating. For the first stages of goldbeating, animal parchment has been used since the seventeenth century; also vegetable parchment in the later stages. Comparative experiments have shown that animal parchment permits only a relatively very slight reduction of the metal sheet; parchment paper allows the metal to be beaten somewhat thinner, but when the limit is passed the metal adheres so firmly to the paper that it cannot be separated without damage. According to a process devised by J. Heinrich (Ger. Pat. 123,197), thin, tough paper of substance of 25 to 30 gm. per square metre is steeped in a hot solution of borax or alum. The paper is stretched over frames, and a coating, first of albumin and then of isinglass solution, is applied, first to one side and then to the other. Papers of various kinds are now used in many goldbeaters' shops, but only for the first stages; the leaf metal is always finished between ordinary goldbeaters' skin. Leaf made from baser metals, however, is beaten throughout between paper. A paper which will serve all the purposes of skin for the manufacture of gold-leaf has yet to be discovered.—W. Theobald in *Papier-Fabrikant*.

BY FAR the most important of the six gold mines in the Dutch East Indies is the Redjang Lebong, Sumatra; during 1910 the value of the output was £403,000 and the dividend was at the rate of 100%. The next largest is the Ketahoen, also in Sumatra; the output was worth £114,000, and the dividend was 20%. There are two producers in Celebes, the Totok and Paleleh, yielding £63,500 and £58,500 during 1910, respectively; the latter paid $7\frac{1}{2}$ % dividend. The Sintoeroe in West Borneo produced £17,500 and made a small profit.

Russian Gold Production in 1911

ST. PETERSBURG CORRESPONDENCE

Reports are beginning to come in, though not of a sufficiently complete character, respecting the gold production in Russia and Siberia during the past year. One is to the effect that in the Urals, while the production in 1910 amounted to about 480 poods* of gold and of platinum to about 334 poods, something like the same totals are to be expected as the results of working last year, 1911, although it is remarkable that, the price of platinum having soared away to a hitherto unattained level, namely, 36,000 to 37,000 rubles per pood, the quantity of platinum produced will be seen to have remained at about the level of the preceding year. That does not, of course, prevent the platinum producers from having made a fine year's business out of the metal last year. The future of the Ural gold industry, it is now seen clearly, must be based on vein gold, because the gold sands that yielded such handsome returns to the gold washers of the past appear to have all that is of real value washed out of them, and it is only the remains of the gold sands that now respond to the efforts of the gold producer. The individual gold washer, in view of the metamorphosis in the industry, will now rapidly disappear, and mining and stamping plants, and all the appliances accompanying the working of gold quartz, will take his place and he will only be an auxiliary.

In the neighboring area—Western Siberia—the gold sands are also weakening, and here, too, the question of vein gold is the one that is occupying the mind of the gold producer, who appears usually in the form of joint-stock companies largely financed, as is known, from outside the country. There is a company, known as the Russian Gold Co., the principal function of which appears to be the financing of various enterprises that yield sufficiently good prospects to justify their being so supported. The production of gold in Western Siberia amounted to about 280 poods in 1910, and in 1911, as in the case of the Urals, is expected to be about equal to this.

Going farther to the famous Olekmin and Vitim river basins where the Lena Gold Co. has operated with such wonderful success—at all events, as a producer—the yield this last year is expected to come out inferior to that of 1910, which was about 845 poods, because the want of water made it difficult in many cases and impossible in others to wash the gold. Other areas now well known as gold-producing ones within the limits of the Russian Empire are the Priamur and the Primorsk. In these two provinces the difficulties attending the production of gold are well known, consisting chiefly in the absence of labor, power, and of the means of communication, not to speak of the faulty state of knowledge there. The production of gold in 1910, which was something like 800 poods in these provinces, has received a serious setback in 1911 and is expected to have made no better than 700 poods when the figures are available. This preliminary statement for 1911 indicates that while the nearer gold-fields, those of the Urals and Western Siberia, will soon have done with dredges, the more distant ones, namely, those of Eastern Siberia and as far northeast as the Telukot peninsula, where, as has been repeatedly pointed out, about 95% of the gold comes from sands, will afford a market for dredges.

The gold sands of Eastern Siberia, of course, vary in richness, and independent workers as well as the strong companies will attack the richer sands first. But as Russian gold reserves are now attracting more attention than ever before, always putting aside the temporary gold fevers such as attended the speculative world a year or two ago, the determination to get the best out of the ground cannot fail to cause those engaged in the work to bring the best appliances, plant, and apparatus into operation that the means at their disposal may make possible. Every year the number of dredges at work in Russia shows an increase, and as the suitability of these for work becomes known

to local men they will, of course, come into greater demand. The chief difficulty for the moment is the obstinacy of the Russian Government, which will not assist the gold industry by allowing foreign dredges free entry or even at a reduced duty so as to bring the lower-grade sands within the reach of profitable operation. At the same time it is notorious that the Russian-made dredge is an exceedingly inferior article and is hardly worth buying except to handle sands of a fair gold content. Its cost is enormous, owing to the protective duty, and the interest chargeable on this prime cost is sufficient to wipe out a considerable margin of the gold content of the sands, as far as the profit and loss account of the respective concerns goes.

But the Russian goldfields, even in the Far East, are not exclusively alluvial. They have been demonstrated in many districts to be largely of gold-bearing veins, and when, as indicated above, the intensive exploitation of the sands has reached its maximum, which must take place at a much more rapid rate now than previously, there will be an appeal to the lower-lying vein gold and a call for the mining plant and machinery required for its exploitation.

Production and Dividends, Portland Mine

The record of production and dividends of the Portland gold mine, Victor, Colorado, covering the period from April 1, 1894, to December 31, 1911, was given in the recently issued annual report.

	Net Tons.	Gross Value.
April 1 to Dec. 31, 1894.....	7,826.286	\$ 553,975.75
Jan. 1 to Dec. 31, 1895.....	31,516.346	1,700,094.89

PERSONAL INJURIES occurring to workers on the Los Angeles aqueduct form the subject of a paragraph in the recently issued report of William Mulholland, chief engineer, for the year ended June 30, 1911. The statistics cover the entire period during which construction has been in progress, approximately five years. From the beginning of construction work on the aqueduct to the date of the report, 653 cases of injury to employees have been reported to the department for investigation. This total, however, includes all cases, no matter how slight the injury and regardless of whether or not the employee lost any time by reason thereof. In pursuance of the policy adopted by the Board of Public Works, half pay has been allowed during the period of disability due to such injuries, to 325 of the injured employees, the total amount paid out on such half-pay allowances being \$12,454.58. In eight cases the employees have made claims for damages, six of these cases resulting in suits for damages. An aggregate sum of \$7750 has been paid in settlement of such damage claims, and there are three suits for damages still pending against the city growing out of personal injuries received by employees on the aqueduct while engaged in the performance of their duties.

*One pood of pure gold is worth \$10,886.72.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

The Estimation of Tonnage

The Editor:

Sir—Mr. Stadler's article in your issue of January 27 will have been welcomed by mill and cyanide men who have to obtain tonnage figures from specific gravity measurements of their pulp. If the author could give some hints on how to obtain the value of 'd' (density of solid) in the case of clayey, graphitic, or otherwise nonhomogeneous ores, his article would be of yet greater value. A short time ago I attempted to obtain the weight of ore passing through a tube-mill by taking the weight and specific gravity of the discharge from the feed cone, but could obtain no reasonably consistent figures. The ore contained quartz with a large amount of clay and oxide of iron; on drying it at steam heat and then determining its density in the usual way, quite discordant results were obtained, probably due to varying oxidation of the iron and dehydration of the alumina. Further attempts were made by taking a litre of pulp in a flask and weighing it, then allowing the solids to settle, and determining the specific gravity of the clear supernatant liquid. As much as possible of this liquid was then siphoned off and the flask filled with a liquid of different specific gravity, such as alcohol or concentrated cyanide solution. After thorough mixing, the flask was again weighed, the solid allowed to settle, and the specific gravity of the supernatant liquid determined. From these weights values for the density of the solid were obtained, but these were scarcely better than those obtained by the drying method. Can Mr. Stadler help those in like difficulty who have not a nice clean ore of regular density to work with?

T. B. GREENFIELD.

El Oro, Mexico, February 8.

[The article on estimation of tonnage, by A. W. Allen, published elsewhere in this issue, will doubtless serve to meet our correspondent's need.—EDITOR.]

The Chicksan Mines, Korea

The Editor:

Sir—In my description of the Chicksan mines, Korea, published in the *Mining and Scientific Press* of April 1, 1911, the following passage occurs, "enough work has been done, however, to show that the vein [at Homune] is of good size and has an average gold content of \$44 per ton." The mine was full of water at the time of my visit to the property, and this statement was based, among other sources of information, upon a report on the Chicksan mines published by the Shibusawa-Asano Mining Partnership, where, following a statement that the assay results are from samples taken from a vein throughout its whole breadth and at several places in the vein, the gold content of the Homune vein is given as 2.21 oz. Edwin W. Mills has since written me that "according to the Koreans, the Homune vein produced a great quantity of gold down to a depth of some 120 to 130 ft. At this point the inflow of water was so great that further work had to be abandoned. Under my direction the main shaft was sunk to a depth of 245 ft., and a vein of quartz was found about 30 ft. from the shaft on the 225-ft. level. But no vein with an average gold content of \$44 per ton has yet been proved at Homune." The wording of the Japanese report is obscure, and as Mr. Mills was at one time superintendent of the property he should be in a position to speak authoritatively regarding it. Mr. Mills further objects to my designating the terms of this concession as favorable, since other companies now operating in Korea enjoy even more favorable terms. It seems to me, how-

ever, more accurate to speak of these latter as unusually favorable, rather than to regard the former as unfavorable. During 1911 the Chicksan Mining Co., an American company, in which the Korean Exploration Co. and the Shibusawa-Asano Mining Partnership hold equal interests, has been finally organized. This company was referred to in my description as though it were already formed, though it was at that time only in process of formation.

Precipitation of Copper From Mine Waters

The Editor:

Sir—A reference to the precipitation of copper from sulphate solution by the use of metallic iron, which does not appear to have come to the attention of your Rio Tinto correspondent, W. G. Nash, and which has considerable interest for students of the subject, is found in the writings of Aureolus Philippus Theophrastus Bombast, of Hohenheim, called 'Paracelsus the Great', who was born about 1493 and died in 1541. In the 'Book concerning the Tincture of the Philosophers', chapter VI, is found the following statement:

"This work is a wonderful one in the light of Nature, viz., that by the Magistery or the operation of the Spagyrist, a metal which formerly existed should perish and another be produced. This fact has rendered that same Aristotle, with his ill-founded philosophy, fatuous. For truly, when the rusties in Hungary cast iron at the proper season into a certain fountain, commonly called Zifferbrunnen, it is consumed into rust and when this is liquefied with a blast-fire, it soon exists as pure Venus [copper], and nevermore returns to iron. Similarly in the mountain commonly called Kutenberg they obtain a lixivium out of marcasites, in which iron is forthwith turned into Venus of a high grade, and more malleable than the other produced by nature."

This statement affords clear proof of the fact that this method of gaining copper was not merely an experiment, but was actually a process commercially resorted to for the purpose of procuring the metal. It is also one of the clearest and most definite statements of the reason why the alchemists believed in the transmutation of metals. If by merely immersing metallic iron in clear spring-water the iron disappears and copper is found in its place, what better evidence could there be? The paragraph cited above is found in the English translation by Arthur Edward White, Volume 1, page 28, published in London in 1894.

Gold Deposited by Magnetic Electric Currents

The Editor:

Sir—The article in a recent issue of the *Mining and Scientific Press*, entitled 'A Mountain of Gold', by T. A. Riekard, and a review of which appeared in the *Literary Digest*, January 13, 1912, impels me to air my views as to the method by which gold is deposited in quartz veins or bodies. I am no geologist or metallurgist, but have spent almost thirty years in the gold-mining field, during which time I have visited and seen many mines and prospects, and have often noted conditions that, to my reasoning, conflict with the universally accepted theory that gold is deposited in quartz by direct precipitation from solution. I cannot reconcile this theory with the fact that orebodies become impoverished in depth. Again, in all artificial precipitation, the gold precipitates as a powder—in little separated granules—and I would judge natural precipitation would do the same. I do not dispute the fact that gold is held in solution in the water of the earth and seas, and possibly some gold is deposited by precipitation directly from the solution, but this must be distributed more uniformly throughout the mass than the rich bunches and nuggets will admit of.

I believe the gold is deposited by magnetic currents, of

which the earth is full. These currents, as they pass back and forth, pick up and carry—in other words, become impregnated with the gold electrons, and are carried by them until they come in contact with quartz, which is a precipitant. The gold once deposited acts as an agent of attraction for more gold, the same as amalgam in a mill; and I hold where rich bunches and nuggets in quartz are found, these currents were strongest and crossed.

There is a belt of country east of the Mother Lode in California that is full of fissures, which are young, geologically speaking, and in many of these rich ore is found at or near the surface, but invariably the amount decreases rapidly with depth, and no great depth at that. The reason is, that these fissures being of recent date and the currents acting slower with depth, there has not been time for enrichment. There is no doubt in my mind but that, in ages to come, all these veins will have been enriched in depth, according to the energy in the currents and the auriferousness of the surrounding country. All the older formations or veins where ore of good value is found near the surface almost invariably are found to contain ore of value to a substantial depth, and if gold is deposited by direct precipitation to a certain depth in old fissures, why not in the younger ones? Further, since gold precipitates in a powdered form artificially, it is reasonable to suppose it would do the same naturally.

I account for the solid nuggets as having been formed

of independent worth, whatever may prove to be the correct explanation. As to the theory he proposes, it has many elements that are attractive and is not necessarily in conflict with that of deposition from solution, since electric currents act through the latter. When the United States Geological Survey was first formed, G. F. Becker undertook field tests as to the strength and possible importance, from the point of view of ore genesis, of the earth currents. The work was expensive, results conflicting, and the matter was given up without definite results. In the decades since these studies were made, much has been learned about magnetism and about methods of measuring currents. The relations of electric currents to solution and deposition of metals are also better understood. Perhaps a re-study of the whole problem now would lead to positive results, either affirmative or negative, and if so, would seem to be well worth while.—EDITOR.]

Heating Cyanide Solutions

The Editor:

Sir—With reference to the benefits derived from slime treatment with heated solution, the one probably least considered is increased filter capacity. I offer the following record of results obtained with two Just laboratory filters run simultaneously, one cold and one at about 100°F., at constant vacuum on identical pulp. The wash solution in each case was cold.

TEST No. 1							
	Time, min.	Solution Displaced.				Cake.	
		e.e.	Value per ton.	KCN.	P.A.	Dry Wt., gm.	Moisture, %
Loading A at 70°F.....	60	1570	\$1.86	1.3	0.5	825	36½
Washing A with cold water.....	60	785	1.45	1.1	0.4		
Loading B at 100°F.....	20	1570	2.08	1.3	0.5	810	34
Washing B with cold water.....	100	1435	0.92	0.55	0.25		
Difference by fire assay in tailing value in favor of heating pulp over loading cold on same length cycle, \$0.28 per ton.							

TEST No. 2							
	Time, min.	Solution Displaced.				Cake.	
		e.e.	Value per ton.	KCN.	P.A.	Dry Wt., gm.	Moisture, %
Loading A at 70°F.....	45	1635	\$1.36	1.05		915	41
Washing A with cold water.....	50	830	1.20				
Loading B at 100°F.....	15	1850	1.36	1.05		885	38
Washing B with cold water.....	80	2460	0.42				
Difference by fire assay in tailing value in favor of heating pulp over loading cold on same length cycle, \$0.28 per ton.							

by the gold electrons being welded together by the magnetic currents at the time of being deposited. The quartz electrons (I use the word electrons, since an electron is supposed to be the ultimate element of matter, hence all matter must resolve itself into electrons) are disintegrated and disposed of by the same method that the gold is deposited. I quite agree with Mr. Rickard in his statement that it is hardly likely that veins of solid gold will ever be discovered, or any deposits larger and richer found than any heretofore known. I believe that it was intended for gold to be a precious metal, to be used for its present purposes, and that the same is true with the other metals, which have all been deposited in proportion to their various uses. Creating a deposit of gold would destroy its value for the purpose intended. My theory of the slow formation of gold in veins and orebodies by magnetic currents does not admit of such a possibility, since geologically the veins and bodies are not old enough. I believe in the distant future, when gold deposits shall have become exhausted, gold will be collected by electro-magnetism (generated at stations for the purpose) from the earth and sea.

F. J. MARTIN.

Angels, California, January 25.

[Mr. Martin need offer no apology for writing. A man need be expert neither as geologist nor metallurgist in order to make observations of value, and Mr. Martin's notes on the relative ages of veins in the California gold belt, based upon his long acquaintance with the region, are

A consideration of the above results will show that in preheating pulp going to the other filters (in this case a very difficult natural slime) the loading period was reduced 60%, the permeability of the cake to wash solutions increased and more undissolved gold put into solution during both loading and washing periods. On the other hand, by preheating, the cycle could have been reduced from 150 minutes to 110 minutes for the same efficiency as when loading cold, increasing the filter capacity 27%. In the mill for which three tests were run the total tonnage could thus have been increased 21%, the capacity of the filter plant being the limiting factor in tonnage treated.

NOEL CUNNINGHAM.

Millers, Nevada, February 3.

Federated Malay States Gold Output

The amount of gold exported during the month of November 1911 was 775 oz. from Raub. The total amount exported during the previous months of the year was: From Seremban, 241.79 oz.; from Raub, 6134 oz.; or a total of 6375.79 oz. The total amount exported to the end of November was: From Seremban, 241.79 oz.; from Raub, 6909.40 oz.; a total of 7150.79 ounces.

SILVER-LEAD, zinc, and copper ores were mined in the Ussuri mining district during 1910 in respective quantities, as follows: 2085 tons, 14,770 tons, and 40 tons.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

COPPER is sometimes added to nickel steel, to the extent of $\frac{1}{2}\%$, for facing armor-plate to resist corrosion.

AMERICAN rosin in large quantities is being sold in Japan, an order of 3000 barrels having been sold at one time through Yokohama importers.

ROLLS for grinding lasted nine years in the Colorado Springs plant of the Portland Gold M. Co., and two new sets of 16 by 32-in. rolls have just been substituted for the old ones, at a cost of \$4034.13.

FIBROUS tale is a variety of tale or soapstone that occurs at but one locality in the United States, Gouverneur, St. Lawrence county, New York. It is used principally to give weight to paper. In 1910 the production was some 70,000 tons, of an average value of a little over \$10 per ton.

LODE locators in California are required by state law to file proof of labor within 30 days after the time limit for performing such labor, but there is no 90-day requirement as to work. The statute merely provides that development work shall be of the character, in the manner, and within the time required by the laws of the United States.

PERMISSIBLE charges for surveys and charges for publication in newspapers have been fixed by the Commissioner of the General Land Office, in accordance with the provisions of the Land Office regulations. In a daily paper the charge may not exceed \$7 for each ten lines for the full period required by law. For a weekly paper, \$5 is the permissible charge. For the publication of citations in contests or hearings, not more than \$8 may be charged for five publications in a weekly paper, or \$10 for publication in a daily paper for thirty days. When it appears that excessive charges have been imposed by any surveyor, prompt steps are taken to correct it.

IN assaying ores containing much copper this metal is largely concentrated in the lead button, making it hard, and necessitating repeated scorifications, and in some cases a preliminary removal of the copper by solution of the ore in nitric acid. This leaves the gold in the insoluble residue, which is filtered off, and the silver in the solution is thrown down by hydrochloric acid. The resulting precipitate of silver chloride is filtered, and the residue and the precipitate are scorified together. Ores containing much arsenic or sulphur are generally roasted at a low heat, and the assay is made on the roasted material, but this must be carefully done, otherwise considerable losses will occur.

TELLURIUM can be detected in ores by a method recently described by G. T. Holloway, who suggests a method of isolating the metal from ore for testing purposes by concentrating it with the gold and silver in a lead button obtained by the ordinary fire assay, it being possible to treat as much as 50 to 60 gm. of ore in this way. The lead button is then dissolved in nitric acid, diluted, and the tellurium precipitated by means of lead foil, the deposit thus obtained being then cleared and tested by concentrated sulphuric acid. If tellurium is present a deep violet color is produced that disappears on further heating. Manganese peroxide, when present, sometimes interferes with this test.

IN explosives for use in the open air, such as, for example, quarrying or railroad excavation, strength and efficiency in removing rock are the qualities that are most important, and usually are the only ones that need consideration in

the selection of a suitable explosive. Explosives that are to be used in tunneling must not only possess strength and efficiency, but also be of such composition that upon exploding they will not give off large quantities of poisonous or offensive gases. In explosives intended for use in coal mines, a further property is most important. Besides possessing the qualities of strength, efficiency in breaking down coal, and freedom from poisonous explosion products, the explosive should be of such nature as not readily to ignite explosive mixtures of gas or coal dust.

WHEN mining claims are re-located in such a way as to forfeit the rights of previous locators, the question as to whether the improvements made are forfeited depends upon whether they can be considered a part of the realty or not. Thus, in California it has been held that an engine and pump became part of the realty, and an engine-house with 15-hp. engine, boiler, and attachments, fastened to the realty and used for development of the claim, were held to be real property, belonging to the re-locator, while a cabin set on blocks and a portable fence were held to be personal property. The land department has held that the improvements re-located cannot be counted as part of the \$500 expenditure required by law.

THE oldest locomotive-manufacturing plant in Sweden, the Trollhättan Mechanical Works, operated by the firm of Nydqvist & Holm, is now constructing its one thousandth locomotive. The plant was established in 1847 principally for making heavy castings and turbines. Locomotive manufacture was begun in 1871. Imports of locomotives into Sweden, mostly from Germany, have been as follows for the last three years for which statistics are available: 1907, 23, worth \$55,370; 1908, 27, worth \$79,830; 1909, 11, worth \$23,350. In 1907 five locomotives were exported from Sweden to Denmark and one to Norway, the total value of the export being \$35,900. In 1908 eight locomotives were exported, all to Denmark, the value being \$90,460. None was exported in 1909.

TO ascertain the velocity of a stream choose a place where the channel is straight for 100 to 200 ft. and has a nearly constant width and depth; lay off on the bank a line 50 or 100 ft. in length, marking each end; then allow small chips to float down the stream, by one of the methods described below, noting the time required for these to traverse the distance laid off on the bank. The surface velocity in feet per second is obtained by dividing the distance in feet passed over by the float by the time in seconds it takes the float to travel this distance. The average of several such determinations will give the mean surface velocity of the stream. This result multiplied by the coefficient 0.80 gives very nearly the mean velocity of the stream. To obtain the area of the cross-section of the stream, stretch a tape from shore to shore and take the depth of the stream at intervals of 2 to 5 ft. The average of these depths may be assumed as the mean depth of the stream. This average multiplied by the total width will give the area of the cross-section of the stream in square feet. The discharge is found by multiplying this cross-section area by the mean velocity, as obtained by the float measurements, the result giving the discharge in second-feet, or, in other words, the number of cubic feet flowing past the point of measurement each second. In determining the velocity for small streams and when only approximate results are desired, the float is placed in the centre of the stream only. For larger streams and when greater accuracy is desired, a tape is stretched across the stream and the distance between the banks is divided into a number of equal spaces or sections. Floats are then allowed to drift down the stream as near as possible to the centre of each of these spaces, the same number of floats being used for each section. The mean surface velocity is then assumed to be the mean of the surface velocities obtained for the several sections. For each float the distance of its starting point from the right bank is recorded as indicated.

Special Correspondence

BULAWAYO, SOUTHERN RHODESIA

DECLINE OF THE BUCKS REEF PROPERTY.—SELUKWE COLUMBIA PROFITS.—TANGANYIKA SMELTER AT LUBUMBASHI.

That Rhodesia, although it possesses numerous large low-grade properties and not a few mines which are enduring in depth, is a country which contains, in the main, erratic quartz shoots of no great extent, has been generally recognized for years past, although in times of great prosperity, as, for instance, during the boom of 1909-1910, this consideration is often very largely disregarded. However, from time to time, events happen which serve to emphasize the truth of the view that in the majority of Southern Rhodesian mines it is unwise to look much beyond the pick or the face of the last blast. The disastrous decline in the fortunes of the Bucks Reef Gold Mines, Ltd., affords a case in point. In 1910 Bucks Reef shares were quoted at 68s. 9d.; today they stand at about 7d. The profit for the year 1910 amounted to £33,115, being at the rate of 82s. 7d. per ton, whereas during the quarter ended September 30, 1911, a profit of only £2167, or 15s. 9d. per ton, was earned. More recently the property has been operated at a loss. The ore reserves were, at the end of September last, only about one-half of what they

TYPICAL SMALL MINE IN RHODESIA.

stood at twelve months previously, and the value of these reserves was also one-half of what it was on September 30, 1910. During the last month or two the stope between the second and third levels in the Prestwood block has come into poor ore, consequently the grade milled for October and November was lower. A little while ago the consulting engineer visited the mine, and reported that, while recent developments have shown an improvement, the ore opened up will not be available for some months.

A satisfactory improvement is to be noted in the report of the Selukwe Columbia Gold Mine, Ltd., not only in the profit earned, but in the underground development as well. For the year ended June 30, 1910, the operating profit was £8869, while in the twelve months ended June 30, 1911, the profit was £18,222. The improvement is in a large measure due to the satisfactory manner in which the lower levels on the main lode have been opened up. On account of this the tonnage milled has been increased, and furthermore, the grade of ore sent to the mill has been augmented. With a view to increasing development, an important addition has been made to the plant during the year in the form of an electric air-compressor at the auxiliary shaft. This compressor, which has a capacity of five drills, will be used for the development of the eastern section, and will allow the six-drill compressor, at the main power station, to be used entirely for the main and No. 2 lodes. To supply the extra electric power required for the compressor, a second generating set has been installed at the main power station.

After years of promises and unfulfilled anticipations, copper smelting operations are at last proceeding in the areas controlled by the Tanganyika Concessions, Ltd., in the Katanga district of the southern Congo and in those portions of Rhodesia which lie to the north of the Zambesi river. In so far as the Tanganyika company is concerned, the smelting work calling for chief remark is the proceeding at Lubumbashi, close to the Star of the Congo mine and the township of Elizabethville. The method of treatment there adopted has been kept much of a secret, but it is pretty generally known that operations are not resulting too satisfactorily. For one thing, the type of furnace employed is said to be unsuitable, and although this was pointed out before they were installed, the Tanganyika Concessions management insisted on carrying through the original program. Then again, the absence of a good quality of coking coal at a reasonable distance from the Tanganyika Concessions mines has been a serious economic drawback. With the existing railway systems, Beira is the nearest port of the Katanga, and coke imported over this route from England costs £14 to £15 per ton, an almost prohibitive price. With a view to remedying matters in this direction, the Tanganyika Concessions, Ltd., recently has been negotiating with the Wankie Colliery Co., whose property is situated in northern Matabeleland. What the eventual result of these negotiations will be is, however, much of a speculation, for the coking possibilities of the Wankie coalfields are problematical. Recently extensive coal deposits have been found on the Congo-Zambesi watershed by the Rhodesian-Katanga Function Railway Co., and development of these is proceeding, but here again, coke is a very questionable matter. Owing to the peculiar geographical position of the Katanga fields, situated, as they are, almost in the heart of Africa, with the nearest port in Portuguese West Africa and as yet unconnected with the copper belt, the outlook for these areas, which are indisputably of highly mineralized nature, is far from bright.

LONDON

CAMBORNE SCHOOL SITUATION ACUTE.—SAN FELIX MINE HAS GOOD ORE RESERVE.—TIN-DREDGING IN SOUTHERN SIAM.

About three months ago I referred in this column to the parlous state of the Camborne Mining School, in Cornwall, and to the short-sighted policy of the governors in not making the most of the new principal, W. Fischer Wilkinson. At the time, I mentioned that the finances were several thousand pounds on the wrong side for the year, and that there were serious thoughts of abandoning the King Edward mine, where the practical lessons are given. The news from Cornwall this week indicates that the position is becoming acute. It is stated that Mr. Wilkinson has handed in his resignation, and that this notice and the question of the mine are to be discussed at the next meeting of governors. In the meantime it is of interest to note that William Thomas, who was considered a likely candidate when Mr. Wilkinson was elected, has just been made outside examiner on mining and surveying in connection with the Royal School of Mines in London. Mr. Thomas was for some years lecturer on mining at Camborne and was induced to leave that position to undertake the reopening of Botallack. This work has proved too much for many other engineers besides Mr. Thomas, who has since then been doing good work as a teacher elsewhere. It may be mentioned that the Royal School of Mines has acquired the Tywarnhaile mine at Porthtowan, between St. Agnes and Redruth, for instruction purposes connected with mine surveying. I ought to add, in connection with the King Edward mine, that when it was acquired there was a full expectation that it would yield a substantial income from the sale of tin concentrate. This hope, however, has not been fulfilled.

Encouraging news comes from the Tominil company, which owns the San Felix silver mine in the Tamazula district of Durango, Mexico. The consulting engineers,

Pearse, Kingston & Browne, write most hopefully of the prospects, which is comforting to Englishmen who put money into the venture. The company was formed in London six years ago to acquire from Parry Gosset this old mine, which had yielded to previous owners some handsome profits from the auriferous silver sulphide ore sold to smelters. Mr. Gosset continued to act as mine manager and consulting engineer, but later was succeeded as manager by G. W. Schneider, who soon disagreed with Mr. Gosset as to the value of the mine. It was then found that the ore left by the old owners was not rich enough for direct shipment. In 1908 the late Ernald Richardson, of Swansea, became interested in the scheme, and supplied additional capital, taking preference shares in the company. He appointed W. R. Francis, a relation, as metallurgist in charge of the cyanide plant it was planned to erect. Soon after this, Mr. Richardson died, and subsequently a general clearance of the managers was made, Messrs. Gosset, Schneider, and Francis resigning. The shareholders asked Pearse, Kingston & Browne to undertake the management, and Mr. Browne and Selwyn Goldstein proceeded to Mexico to reexamine the mine and reorganize the metallurgical plant. They found things in some confusion and were obliged to recommend the expenditure of further capital for development of the mine and for putting the cyanide plant in order. Accordingly, in August 1910, the company was reconstructed. The par value of the shares was reduced by half, and the new ordinary shares were issued with a liability of two shillings, the holders of the old preference shares being given new ordinary shares carrying no liability. The Mexican revolution delayed operations and the reorganized mill ran only intermittently during the year 1911. The reports now at hand show that the mill is paying expenses, and dividends are within sight. The development work has given most encouraging results and a substantial reserve of ore has been developed, estimated to yield £3. per ton. After so many years of disappointment, the shareholders are now in more amiable mood.

The possibilities of the southern part of Siam as a field for tin-dredging have received much attention during the last two or three years, and just recently several engineers have been sent to make further investigations. This part of Siam is really the northern end of the Malay peninsula, and as the rich tin gravels of Perak are almost adjoining, many promoters have argued that there is here a profitable sphere for operations. There are two companies dredging for tin in southern Siam, and they are both obtaining excellent results from gravel which contains about one pound of cassiterite per cubic yard. One is the Tongkah Harbour Tin Dredging Co., which was formed three years ago by people in Tasmania. Curiously enough, violent opposition was subsequently encountered in Australia among the shareholders, who decided to send independent experts to make a further examination of the gravel. Bitter controversy raged for some time between the directors and these experts, the latter alleging that the property was far from being the profitable venture it was supposed to be. With all these eminent people in disagreement, the only thing to do was to await results. It has surprised Englishmen to find that the directors have so far 'made good'. The profit for the past year has been no less than £76,139, derived from the treatment of 2,217,343 cu. yd. of gravel. The production was 1142 tons of tin concentrate, which sold for £117,487, and the total costs of all sorts were £41,348. The detailed figures were: yield, 1.15 lb. per cu. yd., valued at 12½d.; cost, 4½d. per cu. yd. The dredges employed were supplied by Werf-Conrad of Holland.

The other company operating in southern Siam is the Renong Dredging Co.; it was formed in London in 1908, Edward T. McCarthy having examined the property and made strictly conservative recommendations. Here also the Werf-Conrad type of dredge was adopted. So far only one has been used, but according to present plans additional property is to be acquired and another dredge built. The performance of the dredge has been excep-

tionally good. During eleven months 698,679 cu. yd. of gravel was treated, yielding 241 tons of cassiterite concentrate averaging 73% metal. This works out at about ¾ lb. per cu. yd., valued at 10¼d. The revenue from the sale was £30,155, and the total expenses were £15,517. The cost per cubic yard was 5d. and the profit 5¼d. Of the profit, £10,187 has been distributed among shareholders and the remainder carried forward as a cash reserve to provide part of the capital required for the second dredge above mentioned. The remainder of the necessary capital is to be raised by debentures or loans.

BOSTON

HUB BROKERS RESENT NEW YORK'S PRETENSIONS AS COPPER TRADING CENTRE.—LAKE PORPHYRIES ACTIVE.—COMMISSIONS, NOT DIVIDENDS, CRITERION IN JUDGING CONSOLIDATIONS.

Notwithstanding that New York has a metal exchange and lays the flattering unction to itself that it is becoming more and more of a copper centre, even at Boston's expense, the time is never likely to come within this generation when Boston will yield its prestige as copper headquarters. Now and then concern is expressed by poorly informed writers lest Boston's glory should depart as a red-metal clearing house, but there never appears to be, upon serious analysis, so much as an appreciable drift in that direction. New York holds the market on Amalgamated, known as 'Big Copper', and the leading mining and smelting interests of the Guggenheims. But even this fact, influential as it is, is not conclusive as to the controlling and representative character of the copper-share market. In New York the Lake stocks, which two or three generations of Bostonians and New Englanders have dealt in prosperously, are little more than names. They convey about as much meaning to the votaries of the New York Stock Exchange as the Comstocks or Kafirs. While Mr. Finlay's conservative views as to the longevity of the Lake district are entitled to serious consideration, the statement may be made without thought of its being challenged, that the copper-share market without the Lake list would look small. While Boston is hospitable to the porphyries, it is still loyal to its first love, the Lake issues, and will be trading in them, whether depleted mines or unscratched prospects, until the end of the chapter. Amalgamated, Utah Copper, and American Smelters may lead the copper market at times, when Boston will be glad to follow at the other end of an arbitrage wire, but nothing short of a revolution in copper valuations and markets will take from Boston its distinctive character as the exponent of the world's second basic metal.

Copper consolidations are all the talk now in Boston. Ray Consolidated has done that which must have seemed inevitable for a long time, in having absorbed Ray Central. As Ray Consolidated and Ray Central are both New York issues, in which Boston specializes only at second hand, the prospect of the estates and companies being coalesced does not affect Boston more than languidly. But the plan to combine Mayflower and Old Colony, both of them Lake stocks and ever near and dear to Boston's heart of hearts, is quite another matter. The estates adjoin and are still in the prospect stage. The proposal to consolidate them has much to commend it in a physical way. The recent important drill discoveries were made on the Mayflower property, but a short distance from the Old Colony boundary line, and the idea is advanced that the two properties can be worked better as a unit. The same conditions apparently apply to both. But both Mayflower and Old Colony, since the first of the year, have been imparting a great deal of new and long-needed life to the local market, each issue being active day after day and producing a good deal of money for Stock Exchange houses in the way of commissions. Boston Stock Exchange memberships are worth from \$25,000 to \$30,000 apiece, ranking in value only next to seats in Wall Street's principal mart, and these investments must yield fitting return. Therefore,

members of the Exchange do not willingly submit to changing conditions, however wholesome and laudable they may otherwise appear, which threaten a deprivation of brokerage fees. Consolidation of offices, conservation of resources, and unity and utility of management are in themselves attractive ends enough, as a matter of course, but commissions, be it remembered, are the breath of the brokers' nostrils. A year ago, when the Calumet & Hecla officials engaged J. Parke Channing at a large reported fee to appraise a number of Lake properties for proposed inclusion in a \$10,000,000 Calumet & Hecla merger, there seemed in truth much to recommend the plan to favorable consideration. It was stated that the merger would effect an economy of at least a million dollars annually in the management of the properties involved. The plan was reasonable enough and seemed as equitable to all the interests concerned as human ability, with its proneness to error, could make it. But the success of the merger meant the removal by absorption from the Boston Stock Exchange and Curb of a number of active stocks, some of them of long standing and of cherished association of ideas, and the Stock Exchange members were at once in open revolt. Recruited as they were by minority recalcitrants from the Michigan mining end, they made successful opposition to the Calumet & Hecla interests and forced them to abandon a merger scheme which was apparently so fair and disinterested as to look to some people positively philanthropic and altruistic. But the merger plan, with all that it had to commend it, clashed with the selfish interests of brokers and against these it did not prevail.

NEW YORK

NO INCREASED DEMAND FOR COPPER SHARES.—BUTTE & SUPERIOR NEW MILL.—CANADIAN NOTES.—STATE DEPARTMENT MAY INTERFERE IN MEXICO.

There is nothing more illogical or curiously contrary and whimsical than the attitude of the market public. For months the accumulated copper surplus has been pointed to as the one thing bound to hold the metal market and, by deduction, the copper-share market, down. The metal market has advanced to 14½¢, on the strength of the reduction in surplus as shown by the January report of the Producers' Association. The surplus is shown to be about 66,000,000 lb., but there has been no resultant activity in copper shares. Whether the public is convinced that the demand for copper metal is due primarily to Government purchases abroad, or to purchases by some big pools who expect to sell to the governments a little later, is not clear, but in spite of the fact that the metal is up and stocks have decreased, there has been no marked inquiry by the public for copper shares. From U. S. Custom House reports it is shown that February exports for the first half of the month ran something over 3,000,000 lb. per day, and if this rate is maintained the month will be a record-breaker in the way of copper exports.

D. C. Jackling says of the Butte & Superior property that it is the largest zinc mine in the world, the ore averaging better than 20% zinc, and concentrate showing 15 oz. silver per ton. The new mill, which will increase the capacity of the plant to 1000 tons of ore per day, will go into commission about June 1. The plant is to be equipped with all of the latest devices. At present the property is shipping 400 or 500 tons per day to the old Heinze plant at Basin. The plans for the equipment of the Inspiration Consolidated are being held up somewhat, waiting for more definite plans concerning transportation. The Arizona & Eastern railroad has its present terminus at Miami, and it will be necessary to build 1½ miles of additional track, in order to reach the Live Oak and Inspiration ground. Negotiations are in hand to provide the necessary right-of-way, and until these are at an end, definite arrangements for the Inspiration mill will be delayed.

While Cobalt has ceased to interest the public, from an investment point of view, the district goes on its way making some new high records from time to time. Ship-

ments last week totaled about \$123,000—a new high record for the output of a single week in the history of the district. The Temiskaming-North Dome controversy is still on, and appeals for proxies are being made to the shareholders by both contending factions. Poreupine district is looking forward to a definite date for the beginning of regular production. The Dome mill is to go into commission on March 23, and the occasion is to be made a gala day in Poreupine. A number of Ontario officials have been invited to attend, and the event is to be given some provincial importance.

The French Government has a watchful eye, evidently, upon the efforts of foreign promoters to reach the savings of the thrifty people of France, all securities which are offered for listing on the Paris Bourse are having more and more of a gauntlet to run. The French market is the principal one for Rio Tintos, which in turn is one of the chief speculative issues in that market, and several American issues are traded in on the Coudisse, which is an unofficial outside market under the control of the Bourse. Ray Consolidated and Chino Copper have both been prepared for listing on the Coudisse, but owing to some further restrictions recently imposed by the French Government and the appointment of a governmental commission to scrutinize the securities traded in, the applications for these issues will have to be made afresh. Comparisons are never in good taste, but it is hard to refrain from saying that if the American public were protected in like manner, it would never assume its present attitude toward mining investments.

The impression seems to be gaining ground that the rise in the silver market has been overdone by speculators in anticipation of the coming of the Indian Government into the market to buy silver for the coinage of rupees. Both silver and copper have been the mediums of heavy speculation in European financial centres in anticipation of governmental needs. In the case of silver, the demands of India and China furnish the ground for heavy buying, while the copper needs of European armaments have provided the speculative basis in the case of the red metal.

The acute situation in Mexico is pressing into public notice more prominently during the past week, and it would be no great matter for surprise if the State Department should find itself compelled to take some immediate action.

August Heckscher, of the New Jersey Zinc Co. and the Oil Fields of Mexico, has been elected a director of the British Columbia Copper Co. to succeed the late Edwin Hawley. During the past year the British Columbia Copper Co. has lost three directors through death, Mr. Hawley, J. C. Reiff, and F. L. Sommer. The annual report, just issued, contains a strong tribute to them. The operations of the company were not particularly satisfactory during the year; the output was, in round numbers, 10,000,000 lb. of copper, as against 7,000,000 lb. last year. But costs were high, about 40,000 tons of coke being imported from Pennsylvania at a cost of \$150,000 above the cost of the same tonnage from the local ovens.

BLACK HILLS, SOUTH DAKOTA

GOLDEN REWARD ROASTER TO BE ERECTED SOON.—WASP NO. 2 RESUMES.—HOMESTAKE POWER PLANT NEARING COMPLETION.—GENERAL NOTES.

All of the machinery for the Golden Reward company's Wedge 75-ton roaster has been delivered, and it will be erected as soon as possible. Excavation was commenced last fall, but work was suspended on account of heavy snows and cold weather. This plant is to be at the Astoria mine, where a large body of sulphide ore has been opened. This material carries a high sulphur content, and will roast easily to a good cyaniding material. Oil will be secured from the Lander, Wyoming, field, about 300 miles distant. At the present time the company's 250-ton cyanide mill at Deadwood is operating only part capacity, and this will not be increased until weather conditions are more favorable.

Mill construction is going forward slowly at the Bis-

marek Consolidated, adjoining the Wasp No. 2, where the severe weather and snow caused a partial suspension. The Wasp No. 2 resumed operations on February 12, after a six weeks' shut-down due to inclement weather. During the time the mill was closed, it was given a general overhauling. The annual report of the company, just issued, shows that during the year 1911 the mine produced 160,860 tons of ore which yielded in the mill \$286,160, or an average of \$1.78 per ton. During the year \$60,000 was paid in dividends, while additional money was spent for improvements. The most important improvements during the year were a steam-shovel for stripping in the open-cut, a No. 6 Gates crusher at the mill, and a commodious boarding and bunk house for employees. The steam-shovel is working satisfactorily, and a similar machine will be placed in the open-cut, for handling ore, early in the spring.

The completion of the Homestake's hydro-electric plant, on Spearfish river, of 6000-hp. capacity, is in sight. The intake dam and tunnel are complete; the generating station has been finished, the generators placed in position, and the work of wiring is well under way; the pole line to Lead, 11 miles, is completed, and the wires strung; the generating station at Lead is finished, and the transformers and switchboard are being placed. Motors of 25 hp. will be used for driving the stamps, each motor of this size operating ten stamps, so that it will require an even hundred of these motors to run the mills. The crushers, which are situated at the shafts where ore is hoisted, will be run by 35-hp. motors, twenty of these being used. Other equipment which will be provided will be for the two cyanide plants, the slime plant, machine-shop, carpenter shop, timber framing, and other surface works, not including hoists or compressors. C. C. Forester, of Denver, has been appointed general manager of the Evans Consolidated property, and will assume his duties at once. This property almost adjoins the Deadwood townsite on the east. A large showing of milling-grade ore has been made, and the first work of the new manager will be to equip the property with a cyanide plant. The money necessary to equip the mill has been raised, the issue of treasury stock which was allotted for this purpose has been oversubscribed, and the money returned to the subscribers who were too late. Work is to be resumed at once on the property of the St. Louis Placer Mines Co., on Judson creek, in southern Lawrence county. This property was purchased late last fall, and before much more than preliminary work had been done, winter interfered. The Boston investors, represented by F. H. Cutting, who purchased the Gladiator mine from Burt Rogers and associates, of Deadwood, have bought two adjoining claims from J. P. Hymer, of Denver, and are now preparing to start development.

SALT LAKE CITY, UTAH

UTAH METAL M. CO. TUNNEL PROGRESSING.—OTHER SIMILAR PROJECTS IN UTAH DISTRICTS.

Within the current year the long tunnel of the Utah Metal M. Co. will be completed. This is one of the most important operations now in progress in the Bingham district. The tunnel, which, when completed, will be about 11,000 ft. long, will traverse the entire Oquirrh range of mountains, from Lark on the eastern side to a point near the Tooele smelter of the International S. & R. Co. on the west. It will not only afford facilities for deep development of known orebodies for several mines, and cheap transportation to the smelter, but it is believed that several new orebodies will be cut. On February 1, 4000 ft. of work remained to be done. From the Tooele side an average progress of 10 ft. per day is being made. On the Bingham side the progress has not been so rapid on account of the soft ground, but the face is now in a harder formation, and it is expected that in the future equally rapid progress can be made on this side. If the rate of 20 ft. per day can be maintained, this will complete the tunnel in 200 days from February 1, or not far from the first of Sep-

tember. The work from the Tooele side is being pushed with hydro-electric power from water sources owned by the company, thus reducing the cost. E. P. Jennings, consulting engineer for the company, states that the Bingham workings are approaching the places where mineral is expected. The face is within 700 ft. of the Mountain Maid ground, which has been opened to a point 230 ft. above the Utah Metal adit level. Porphyry containing pyrite and copper stains is already being penetrated. This face is in over 600 ft. The Tooele side is in close to 7000 ft., and Mr. Jennings expects that within another 1000 ft. it will cut the Jordan and Commercial line, from which formation a large portion of the silver-lead ores of Bingham have come. The present management of the company has expended about \$250,000, since November 1909 on the work and is financed to carry it to completion. The most interesting part of the work, from the standpoint of mineral development, is ahead, and the progress is being closely watched at Bingham.

Arrangements have been made to finance another Bingham adit project—the Montana-Bingham. A company has been organized to provide funds to extend this adit 4000 ft., tapping veins of the Bingham Amalgamated, Congor, Fortuna, and Starless, with all of which companies agreements have been made for the development of the ground and the transportation of ore. A similar project is now being agitated in the Cottonwood district, but as yet it has not reached the tangible stage with money behind it. One of the latest plans under discussion is to start a tunnel on the old Colonial property in Big Cottonwood, and carrying it 15,000 ft. to the divide. Another 1500 ft. would bring it under some of the leading properties on the Alta side. A plan less ambitious but more feasible is that of the new Michigan-Utah Consolidated company. This corporation is merging the Utah Mines Coalition, City Rocks, Grizzly, and other properties which already have been good producers and will operate them in unison.

LAUNCESTON, TASMANIA

PRESENT CONDITION OF THE TASMANIA GOLD MINING COMPANY.

The gold mine in Tasmania controlled by John Taylor & Sons is giving disappointing results. The company, called the Tasmania Gold M. Co., was formed in 1903 to acquire properties at Beaconsfield, Tasmania, that previously had been operated by a local company. These mines had been successful gold producers, but owing to the increase of the flow of water in depth, the continued working of the property involved a far greater expenditure on pumping plant than local owners could afford. This capital was provided on the flotation of the London company, and the plant laid down in one of Henry Davey's best examples of the modern Cornish pump. The water trouble has not, however, been the only drawback, for the lode has proved of irregular content in depth. In 1909 the grade fell seriously, and in October 1910 it was found necessary to reconstruct the company in order to provide new capital. The nominal capital was then reduced from £500,000 to £250,000 by altering the denomination of the shares from £1 to 10s., and the new shares were issued credited with 7s. 6d. paid, thus carrying a liability of 2s. 6d., sufficient to provide £62,500 in cash. The reconstruction of the company was successfully carried through, and one shilling per share has been called up. During the period under review, 52,968 tons of ore was raised, from which 23,143 oz. gold was recovered, realizing £97,820. The expenditure at the mine and in England amounted to \$101,913, leaving a loss of £4020. The development work has been actively conducted on the deeper levels, especially on the 1370-ft. level east. The results have not been altogether satisfactory, owing to the presence of a horse of country rock. The shaft tapping the lower levels has been sunk to 1530 ft., and a drift is being started at 1500 ft. The results here obtained will determine the future of the company. The ore reserve above the 1370-ft. level is estimated at 43,084 tons, in addition to which 27,288 tons is 'partly developed,' and 30,000 tons is 'probable.' The company has never paid any dividends.

General Mining News

ALASKA

PRINCE WILLIAM SOUND

A new orebody, assaying 4% copper, recently was discovered on the property of the Fidalgo Bay Alaska Copper Co., says the *Valdez Prospector*. Thomas Donahue is president of the company. The second vein on the Cliff property has been intersected on the 400-ft. level, it is reported. The lower adit driven by Todd Date and Patsy Hogan of the Mayfield company on the Mayfield group, Columbia glacier, has intersected an orebody assaying about \$65 per ton. The adit is in 180 ft., and is 200 ft. below the upper adit.

ARIZONA

COCHISE COUNTY

The 15 claims and two mill-sites of the Copper King group will be sold at sheriff's sale, March 4, to satisfy a judgment secured by W. A. Cummings against T. F. Gilbane, says a report from Tombstone. The property, which is near the South pass, has been an object of litigation for several years.

GILA COUNTY

(Special Correspondence.—The enlargement of No. 2 shaft at the Live Oak from 2 to 3 compartments has

MAP OF ARIZONA.

been started. Jack Melvor has the contract for the work and has hired some of the best miners of the district. The shaft is 928 ft. deep and will be enlarged by raising from four or five different points. It is expected that the work will require about two and a half months. In the meantime a double-drum hoist and two 150-hp. boilers will be erected, and development of the orebody from this shaft will be resumed as soon as the shaft work is finished. Development is now in progress from No. 1 shaft, near the eastern end of the property. M. E. McCarthy is superintendent. The churn-drill hole that is being drilled in the bottom of the 400-ft. shaft of the Barney group, under option to the Lewisohns, has passed out of the schist into dacite and is now over 800 ft. below the collar of the shaft. E. B. Tinker is superintendent of the property. Work is progressing on the water-supply dam for the Inspiration Consolidated concentrator, and tests are still being conducted by J. M. Callow in the experimental mill. A trestle is being built from the mouth of the main adit to the site of the new steel warehouse. The Miami mine is producing at the rate of over 2500

tons per day from the 420-ft. level, and development on the 570-ft. level continues. Five units of the concentrator are in operation. In place of the rigid rolls, a Hardinge ball-mill is being tried out in one unit and a set of spring rolls in another. Nearly 800 men are employed.

Globe, February 16.

At the annual meeting of the stockholders of the Southwestern Miami Development Co. held at Globe on February 12, it was voted to increase the capitalization from 50,000 shares to 100,000 shares, par value \$5. The increase of 50,000 shares was taken by William A. Paine, of the firm of Paine, Webber & Co. of Boston, and associates, at \$4 per share for \$2 paid in stock, which, with the money received from the recent call of \$1 per share on 35,000 shares, will give over \$200,000 for payments on the property and for its development. There are now issued and outstanding 15,000 shares of fully paid stock, and 85,000 shares of \$2 paid stock upon which \$3 per share can still be called, giving an additional \$255,000, should it become necessary. It is proposed to purchase two additional churn-drills, making three in all, and continue the exploration of the property. It is estimated that the money now on hand will be sufficient to meet the payments on the property, purchase the additional equipment, and operate the three churn-drills for nearly two years, or until January 1, 1914. The officers of the company are: President, George F. Ruez, Ishpeming, Michigan; vice-president, R. T. McKeever, vice-president of the Copper Range Consolidated company; secretary and treasurer, Robert H. Gross, president of the East Butte Copper M. Co. The above with the following make up the board of directors: T. S. Dee, of Paine, Webber & Co., Boston, Mass.; D. T. Kennedy, Boston, Mass.; George J. Maas, Negaunee, Mich.; and H. B. Howland, Duluth, Minn., formerly president of the Live Oak Development Co. and now a director of the Inspiration Consolidated Copper Company.

MARICOPA COUNTY

H. William Stevens, W. J. Martin, and associates, have acquired the Bonanza and Golden Eagle groups of claims. The property has a 40-stamp mill, compressor, and other equipment. A company will be organized for developing the property, says a Phoenix despatch.

SANTA CRUZ COUNTY

The Virginia Con. M. & M. Co., capitalized at \$1,000,000 and with headquarters at Nogales, has been incorporated by C. L. Beatty, E. L. Ish, and R. H. Colvin.

YAVAPAI COUNTY

The American Gold company has acquired the Farley group of claims, near Columbia, and has started development there. The Allen mill, taken over with the property, is being remodeled by R. C. Henson, and a cyanide equipment will be added. George Dillard is general manager for the company.

CALIFORNIA

BUTTE COUNTY

Vuba Consolidated dredge No. 13, at Oroville, has broken the record for low cost in placer mining. The dredge, which cost \$327,000, last month handled 320,000 cu. yd. of gravel, at a cost of 1.85c. per cu. yd., says a report in the *Boston News Bureau*. The property is now yielding an annual profit of \$1,200,000 to Mrs. R. D. Evans, of Boston, it is said. R. D. Evans paid \$600,000 for a controlling interest in the company, which is claimed to be the only California gold-mining company to return to Boston investors the original investment.

INYO COUNTY

It is reported that a lens of ore averaging over \$100 per ton has been discovered on the Whipsaw claim of the Keane Wonder M. Co., near the Nevada line. The first two years of operation of the Keane Wonder mill showed an average yield of \$12 per ton, but lately richer ore has been mined.

MOHOC COUNTY

(Special Correspondence.) While promotion of com-

panies in the High Grade district seems to have attracted more attention than actual mine development, it is true that operations have been handicapped by the inclement weather. It is expected that development will be in full swing in June, or perhaps earlier. While Eastern, as well as Colorado, Spokane, and Los Angeles capitalists have shown some interest in the district, it is said on good authority that no strictly cash deals have been made for any properties since the reported rich discoveries on the Sunshine, Modoc, Mountain View, and other claims. So far all transactions have been in the form of options or bonds. Many reports from the district have been grossly exaggerated, but conditions are favorable for developing mines.

Alturas, February 17.

NEVADA COUNTY

While excavating for the new Elks' hall at Grass Valley, ribbon quartz and a gravel deposit were found which mining men considered indicative of valuable ore in the vicinity. No attempt at an assay has been made.

PLACER COUNTY

C. G. Ward and Steven Rogers, of the Ward Consolidated company, have discovered an 8-inch vein of gold quartz assaying over \$4000 per ton, says a newspaper report from Auburn. At a depth of 50 ft. they intersected a 'kidney' of tungsten ore. The property is in the Ophir district.

SHASTA COUNTY

It is reported that the Victor and Grand Central properties, in the Harrison gulch district, have been consolidated.

The Mount Shasta mine has been sold to A. A. Lindsay and associates, of Portland, Oregon, for \$35,000, by Alden Anderson. Mr. Anderson recently bought the assets of the defunct Bank of Shasta County and established a new bank. The mine was among the assets. Mr. Anderson also sold two claims adjoining the Michigan property to the Pioneer Gold & Silver Co., of New York. The company, it is rumored, is about to buy the Bully Cave mine.

SISKIYOU COUNTY

(Special Correspondence.)—The Blue Ledge Copper Co. has obtained patents on 27 claims in the Blue Ledge district, about four miles south of the California-Oregon line. The company has conducted extensive development during the past eight years, expending about \$700,000 in the work. A main adit and numerous auxiliary drifts and levels have been driven. It is reported that the company plans the building of a railroad from the district of Medford, Oregon, and the possible construction of a smelting plant. The developed ores carry copper and some gold. Robert A. Towne and associates of New York are chiefly interested. The Spring Gulch Tunnel Co. is developing good ore near Yreka and installing machinery for its treatment. About 45 men are working at the Jilson mine, near Montague, and the mill is running steadily. The Siskiyou Electric Power Co. is extending a power-line to the property, and electricity will be employed as soon as the water-supply falls short. The London syndicate is pushing its adit to intersect the main shoot in the Gum Boot mine.

Yreka, February 17.

TRINITY COUNTY

It is said that the Trinity Dredging Co. by June 1 will be operating one of the largest gold-dredges in the state, about five miles from Lewiston, on the Trinity river. The dredge is now under construction, and will have a hull 109 ft. long and 46 ft. wide. The buckets are to be of manganese steel. The dredge will have a capacity of between 100,000 and 110,000 cu. yd. of gravel per month.

TUOLUMNE COUNTY

The shaft of the Tarantula mine of the United Gold M. & M. Co. has attained a depth of 950 ft. below the outcrop. Sinking is still in progress, while explorations to the north of the shaft are being continued without interruption. This company is also drilling large areas of gravel at Yankee Hill, near Columbia, and it is expected

that active mining operations will be commenced during the summer.

YUBA COUNTY

Press rumors are to the effect that a \$20,000 mill and hoist will be erected at the Manzanita mine.

It is rumored that the Dewey mine, near Rackberry, is to be reopened, although the name of the operating company has not been announced.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A streak of ore from 3 to 6 in. wide has been uncovered on the foot-wall of the Silver Stream vein, intersected by the Hamill adit in West Argentine, that shows assay-values of 2000 oz. silver per ton. E. Le Neve Foster, of Denver, is manager. A shipment of two carloads of zinc ore was made this week from the Gambetta mine. Returns of 52% zinc and 36 oz. silver per ton were received. B. J. O'Connell is manager. Parachini & Co., lessees of the Seven-Thirty mine, shipped 22 tons of lead ore this week that milled 59 oz. silver and 40% lead. Stopping is under way on a streak that is 14 in. wide. The Diamond mill will be brought into commission next week. Dump matter will be treated exclusively. H. C. Reno is manager of the plant.

Georgetown, February 17.

TELLER COUNTY (CRIPPLE CREEK)

The report of the Doctor-Jack Pot M. Co. for the last quarter of 1911 shows that the company last year produced 4980 tons of ore, of an average assay-value of \$15.26. The treasurer's report shows an increase for the quarter of \$463, a smaller increase than for the preceding quarter owing to expenditures for taxes and the subscription to the drainage adit, and to the \$1500 charged against depreciation. The Mary McKinney has announced the intersection of the vein at a point 100 ft. below the old water-level. No decision has been handed down by the United States Appellate Court in the Work M. & M. Co. suit. The El Paso Con. G. M. Co. has declared a dividend of 1c. per share, payable February 29 to stockholders of record February 17. The dividend will mean the disbursement of \$24,500.

IDAHO

IDAHO COUNTY

Rumors from Golden are to the effect that unusually rich ore has been discovered in the lower cross-cut adit of the Wonder property. The Center Star is to resume operation, under the direction of Charles Tiedeman.

SHOSHONE COUNTY

The earnings of the Federal M. & S. Co. for December, after all charges, totaled \$79,800, or about \$10,000 in excess of the preferred dividend requirements, says the *Wallace Miner*. The earnings for the four months of the company's 1911-1912 fiscal year which have been reported total \$277,600, or only \$2076 short of the preferred dividend requirements. At the end of the first quarter the earnings showed \$11,957 less than the preferred dividends for the quarter.

MONTANA

LINCOLN COUNTY

(Special Correspondence.)—Showing 11 ft. of rich ore with the hanging wall not yet in sight, the vein at the Snowshoe mine has just been tapped on the 500-ft. level. Sinking the shaft to this level was completed only recently, and it is the deepest by far of those in the Libby district. The Snowshoe was purchased by E. H. Wilson about a year ago, and since last spring has been operated steadily. The ore carries silver, lead, and gold.

Libby, February 17.

SILVERBOW COUNTY

(Special Correspondence.)—The Laurium-Montana M. Co. held its annual meeting here. The main adit of the mine is now in 300 ft. The directors elected officers for the year. The financial condition of the company is suffi-

ciently strong to carry on all development planned. J. Bruce Kremer, who is a director and also counsel for the Butte & Superior company, and J. M. Hyde, who installed the flotation plant for the company at the Basin works, have left for New York, where, it is stated, a movement is on foot to acquire other property in the vicinity of the company's plant. The reports of the president and treasurer show that the company is in good condition. The new concentrator, which was originally intended to have a capacity of 500 tons per day, will have a capacity of 750 tons per day. The Colorado mine of the Davis-Daly company is making ore shipments averaging 50 tons per day, divided between the Washoe and East Butte smelters. The shipments are more than sufficient to pay all obligations. The ore is coming from the 1700-ft. level. W. F. Fisher, the new manager for the company, said that it had been decided to sink the shaft another 200 ft. It is expected that at that depth a larger and richer body of ore will be found.

Butte, February 17.

(Special Correspondence.)—Bruce McKelvey, of Hayden, Stone & Co., is expected here in a few days with some of the directors of the Butte & Superior company, to make an inspection of the company's property and to see what progress is being made in the construction of the concentrator. The building will be closed in by the last of the month and some of the machinery in place. A. B. Wolvin, president of the company, says that unless something unforeseen occurs, the concentrator will be ready to go into commission by the middle of May, which will be at least two weeks ahead of the contract time, June 1. As the lease on the Basin works does not expire until June 30, this will give the company six weeks to remove whatever machinery is required from Basin and have the mill in operation by at least the middle of June, or possibly earlier. Mr. Wolvin says that the company has been earning \$30,000 per month from the ore treated at the Basin works; but, with improved methods, some new machinery, and the saving in railroad haulage of the ore backward and forward, the company will be in a position to increase its net earnings to \$50,000 per month. When asked about a report that there might be a dividend in the near future, he declined to commit himself, but did say that he would not be surprised if the stockholders received something on their investment about the close of the year.

Butte, February 13.

The Barnes-King company expects to be in a position in the course of three weeks to take over a promising property in the hope that some day the stockholders will get some return on the money they have had tied up for several years.

The new surface plant of the Tuolumne company has been completed and steam turned in, but it will be about the first of the month before it is put into commission. As soon as everything is working smoothly, the production will be increased to about 400 tons per day, and the work of sinking the shaft from the 1800-ft. level to a depth of 2000 ft. will be commenced.

NEVADA

CLARK COUNTY

Ore similar to that of the Florence and Mohawk is said to have been discovered on the property of the South Nevada G. M. Co., seven miles east of Las Vegas. The ore is said to assay as high as \$40 per ton. Paul Watelet is general manager for the company.

HUMBOLDT COUNTY

The Seven Troughs Coalition company in January produced in bullion and concentrate \$40,074, according to late reports, exclusive of the clean-up of the cyanide plant, not yet made, which would amount to about \$4000. The run for the past two months has totaled more than \$85,000. In January the recovery was 98.79%, according to the official report.

NYE COUNTY

(Special Correspondence.)—The 10-stamp mill of the

MacNamara is in steady operation and is doing excellent work. The stamps are 1500 lb. each and 5 tons per stamp are now being crushed, though it is expected to increase this to 7½ tons as soon as all the machinery has been in operation long enough to get 'warmed up.' The pulp is ground in a tube-mill and then agitated in an agitator of the Trent type, but devised by Herbert Haas, the metallurgist for the company. Filtering is done in a leaf filter and a novel device is employed to secure economy of water used in discharging the washed cake, as the cost of water is 75c. per 1000 gal. and any excess water used in discharging is a corresponding loss. The filter-leaves discharge into a pointed box provided with a screw conveyor at the bottom. Between the blades of the screw are radial arms which thoroughly triturate the cake and produce a fluid pulp with a minimum of water. As the country is rather flat and dumping room at a corresponding premium, this adds greatly to economy of operation.

Tonopah, February 21.

It is announced that the Tonopah M. Co. has secured an option on a seven-tenths interest in the Tecopa Con. M. Co. The financing of the company will depend on the report on the property to be made by J. E. Spurr, second vice-president of and consulting engineer to the Tonopah

BELMONT SHAFT.

company. It is rumored that the capital stock of the Tecopa company may be increased from \$3,000,000 to \$10,000,000.

The Tonopah Belmont Development Co. in January produced 3729 oz. gold and 366,319 oz. silver. During the month 7698 tons of ore was milled, and 2665 tons shipped to the smelter, making a total production of 10,363 tons of ore. The profit for the month was \$151,487. The Tonopah M. Co. of Nevada in January milled 14,943 tons of ore, averaging \$18.60 per ton. During the month 269,635 oz. gold and silver bullion, valued at \$214,070, and 112 tons concentrate, valued at \$39,530, were shipped. The profit for the month was \$143,340.

The production of the Tonopah district during the week ended February 17 amounted to 8832 tons of ore, as follows: Tonopah Mining, 3400 tons; Belmont, 2400 tons; Montana-Tonopah, 952 tons; Tonopah Extension, 960 tons; West End, 770 tons; and the MacNamara, 350 tons of ore.

STOREY COUNTY

Owing to the construction of a bulkhead and some re-timbering, the Ophir company last week produced only 236 tons of ore, which had a gross assay-value of about \$5660. Much development activity marked the week at the Consolidated Virginia, although only 29 cars of ore, assaying about \$19 per ton, was saved. The Crown Point, from the 1400-ft. level and stope No. 3, produced 636 cars of ore, valued at \$4723. The Yellow Jacket mill is still running at full capacity. With what is being mined each week and what is stored ready for treatment, the mill will be running for the rest of the month. The Mexican mill was shut down for two days on account of changes made in the classifying and thickening system, but despite the 65% running time, 323 tons of ore was crushed. The changes were completed February 15.

WHITE PINE COUNTY

The Lead King M. & M. Co. has discovered on its property a vein of steel galena ore, assaying about 80% lead and 6% silver per ton, says a report from Ely. The property is known as the Morning Star claim, and is situated east of the McGill smelter.

NEW MEXICO

SOCORRO COUNTY

The Juanita mine, at Kelly, has been reopened by local merchants. Lee Terry is manager of the property, which contains zinc carbonate ore.

(Special Correspondence.)—During January 4800 tons of ore was milled at the Socorro Mines, yielding 7 tons of concentrate and 28,000 oz. of gold and silver bullion. On account of a shortage of wood at the old power-plant, the mill closed on January 30, but will start as soon as the new power-plant is in commission, probably in the present week. Fuel oil will be used.

About 45 ft. of development work was done at the Deadwood Mines property the past week. The mill handled 200 tons of ore. The Ernestine M. Co.'s bullion clean-up for the first ten-day period in February is being smelted. The past week's tonnage was 694, with 64 sacks of concentrate. The ore-shoot recently discovered is one of the largest and richest in the Mogollons. At the Oaks Company's property the head-frame, hoist, and equipment at the South shaft of the Pacific mine will be placed in commission this week. The shaft will then be sunk as rapidly as possible, with two shifts. During January, 162 tons of ore was treated in the Deadwood mill. Work continues in the main drainage and transportation adit. At the Deep Down property the lessees will soon have the old workings in shape for production, when ore will be sent to the Deadwood mill for treatment. A gasoline hoist has been ordered for the mine.

Mogollon, February 16.

OREGON

JACKSON COUNTY

H. L. Herzinger, of Grants Pass, was elected president of the Southern Oregon and North California Mining Congress at the session recently held at Medford, Yreka, California, was chosen for the next meeting, to be held June 18. A resolution was passed condemning what is considered arbitrary interference with miners on the public domain in regard to the use of timber, and delay in granting patents. A resolution of thanks to W. B. Heyburn, United States Senator from Idaho, was passed, thanking him for his attitude toward recent bills affecting the mining industry.

UTAH

JUAB COUNTY (TINTIC DISTRICT)

The Tintic M. & D. Co. has resumed operation at its property, which has been idle for several years. The company, which is a close corporation, owns a group of claims adjoining the Mammoth and Gold Chain properties. Since sinking was resumed, a little over a month ago, at the Eagle & Blue Bell mine, the shaft has been put down about 170 ft. William Owens, superintendent for the company, believes his men can maintain a total of 130 ft. per month. The Tintic Central has resumed development, with Thomas Holdaway as superintendent. The company recently levied an assessment of $\frac{1}{2}$ c. per share. The assessment will be delinquent March 9, and the sale day is set for March 27.

SALT LAKE COUNTY

The annual report of the Utah Metal M. Co., operating in the Bingham Canyon district, states that the 11,000-ft. tunnel is to be completed within six months. To date \$242,606 has been expended, on machinery, labor, and supplies. On January 27, says the report, the tunnel was in 548 ft. from the Bingham side of the mountain, and it is believed that a rate of about 10 ft. per day can be maintained. The tunnel is in 6796 ft. from the Tooele side, and is being driven at a rate of about 70 ft. per week.

All of the work from the Tooele side is by hydro-electric power generated at sites owned by the company. E. P. Jennings, consulting engineer, reported that the Bingham end of the tunnel has penetrated a hard porphyry rock, filled with pyrite and with some copper stains in the seams. It is believed that orebodies may be intersected in the near future.

The Utah Copper Co., according to a recent report, will have all 13 units of the Arthur mill in operation by August 1. This will give the plant a capacity of 9000 tons of ore per day, which, added to the 12,000 tons capacity of the Magna mill, will make a total for the company of 21,000 tons per day, against the 17,000 tons capacity the company has at present. The eighth unit of the Arthur is to be put in operation about March 1, and every month thereafter one new rebuilt unit will be started, if the present plans are carried out. It is said that the Utah Copper Co. has ore reserves of 100,000,000 tons of fairly well assured, in addition to the 200,000,000 tons of proved ore reserves. The development to date has resulted in the extraction of about 16,500,000 tons.

SUMMIT COUNTY

While lack of water is hindering operation at the mill, the Daly-Judge mine is maintaining its usual production of ore. The cement work for the bad stretch in the Snake creek adit, in charge of Oscar Friendly, will be completed about March 1, when work will be resumed in the face of the bore. Shipments from Park City during January amounted to 7346 tons of ore. Lack of water is handicapping also the Daly West mill. The company's affairs are in good condition, recently stated H. G. McMillian, general manager for the company, and operation will be resumed later.

WASHINGTON

STEVENS COUNTY

Fred Dodge, lessee at the Providence mine, near Turk, has shipped a carload of lead-silver ore to the smelter. The Deertrail company has shut down, owing to the deep snow, but will resume early in the spring. The Germania mine will be out of the receiver's hands and will resume operation in the spring, according to a recent rumor. The mine has 400 ft. of development work, and it is reported that a large tungsten orebody has been intersected. A. H. Stiles, manager for the Cedar Canyon S. & R. Co., for several months has been building roads, as well as erecting an ore-house and making other improvements. Sinking on the vein has been resumed. A car of medium-grade ore will be ready for shipment soon.

CANADA

BRITISH COLUMBIA

In the No. 1 or lower adit of the Cascade Falls M. Co.'s property, at a distance 130 ft. from the portal, the orebody which also is being developed in the No. 2 adit, has been intersected. F. B. Hume is superintendent for the company.

The British Columbia Copper Co. in the year ended November 30, 1911, produced 9,944,987 lb. of copper, against 7,143,456 lb. in the preceding year. Owing to the low price of copper and unfavorable operating conditions, the profit for the year was only \$133,929, against \$256,561 for the year before, and \$204,973 for the year ended November 30, 1909. The cost, it is believed, was about 11c. per pound, against 9c. for the preceding year. The earnings fell short of the dividends paid, by \$14,000. It is rumored that the company's assets, including copper on hand, are scarcely in excess of its current liabilities, but it is not believed that the obstacles hindering last year's operation will appear again.

YUKON

Gravel running 40 to 50c. for the 7-pan bucket is reported by F. H. Back on No. 5 on the left fork of Nansen creek. Twenty-five men are wintering on Nansen creek. Nansen creek is on the main Dawson-Whitehorse road, and is 40 miles west of the Yukon river. Carmack's is the nearest Yukon river port.

MEXICO**CHIHUAHUA**

Banks in Parral are reported to be secreting their funds, and families are leaving the town on every train through fear of the revolutionists. Recent advices state that the principal mines throughout the state are still operating, as a general rule, and it is asserted that they will continue to do so unless the situation becomes more threatening. The Guadalupe mine, of which Vicente Visconti is manager, in the Parral district, has closed down, and will not resume until the political situation is quieter. The principal mines in the Santa Eulalia district are reported to have a full complement of laborers.

COAHUILA

The Coahuila M. & S. Co. is to resume operation at the Media Luna property, near La Mancha, according to a recent report. The Reyes M. & S. Co. also is planning to resume development of its property west of La Mancha, which is a station on the National Railways system.

HIDALGO

Much activity is expected at the San Rafael y Anexas property as the result of the arrangements for the quotation of the company's shares on the Paris Bourse. Stockholders have been given an opportunity to exchange the old shares for the new issue, at the National Bank, in Mexico City, at the rate of ten new shares for one of the old free shares, five for one of the *aviadas* of San Rafael, nine for one of the *aviadas* of La Sorpresa, and six for one of the *aviadas* of La Soledad.

SINALOA

(Special Correspondence.)—On the west coast of Mexico there have been no signs of the revolution in Chihuahua. Mining development is quiet, but land enterprises seem to command a great deal of attention. There has been much small-pox, of the black variety, around Mazatlan, Guaymas, and Chinipas.

Mazatlan, February 17.

Among the Copper Mines

THE HANCOCK SHAFT, in the Lake district, is expected to intersect the Pewabic lode in the near future. A mill test of ore from the No. 3 vein showed a yield of about 18 lb. per ton.

THE MIAMI COPPER CO. is said to be maintaining costs at between 8 and 8½¢, per lb. It is producing about 2,500,000 lb. of copper per month, with five units of the concentrator in commission. With the starting of the sixth unit in the not far distant future, it is said a rate of production will be maintained of 3,000,000 lb. per month, or about 36,000,000 lb. per year.

ON THE EAST DRIFT of the 1800-ft. level of the Tuolumne, an orebody about 25 ft. wide and carrying about 8 ft. of copper glance and bornite, has been opened. Since intersected by the cross-cut, the drift has been in ore running about 6% copper, but the development work of the past few days has brought out ore much richer than any yet found in other portions of the mine.

ACCORDING TO CURRENT GOSSIP, says the latest Hayden Stone & Co. letter, the second stamp of the Winona mill, the only inland mill in the Michigan district, is to commence doing duty within a brief period. The first stamp was placed in commission last March, and for the seven months following the yield per ton was reported at slightly under 13 lb., which probably spelled an operating deficit. Mill adjustments are credited in part for the subsequent somewhat improved recovery, the figures for recent period being about 14 lb. per ton.

F. AUGUSTUS HEINZE is said to be endeavoring to secure some claims near the Hidden Lake property, just outside of Anaconda. The commencement of work on the extension of the railroad to the Georgetown district is attract-

ing people from all over the country, as there is no doubt the district has some valuable properties which can be worked to advantage when a railway will bring the ore to the smelter for treatment. The Hidden Lake is shipping ore regularly to the Washoe smelter. After a conference between a Heinze representative and some of the owners of the Hidden Lake mine both parties acknowledged that a deal was under consideration, but declined to make any statement.

THE ACTIVE DEMAND for both standard and refined copper during the months of November and December, says the current James Lewis & Son's report, has been followed during January by dull markets, consumers buying sparingly while speculators have sold to secure their profits. The further material improvement in the statistical position has consequently had no effect, being neutralized by the weakness of the New York Stock Exchange and fall in the shares of copper producing companies. Opening at £62 13s. 9d. for cash, Standard copper advanced to £64 on January 3, fell to £62 18s. 9d. next day, and again advanced to £64 5s. on the 8th. From this point it declined to £61 15s. on the 16th, but recovered to £63 5s. on the 17th, falling to £60 17s. 6d. on the 29th. This price induced active buying, and up to £62 7s. 6d. was paid for cash and £63 3s. 9d. for three months on the 31st. February 1 cash fell to £61 10s., but closing prices are £61 16s. 3d. cash and £62 12s. 6d. three months. Sales total about 45,000 tons. American refiners having previously sold large quantities of electrolytic for prompt and forward delivery, raised their price to 14½¢, per pound, and maintained it at this until a few days ago, when more desire was shown to make further sales by one large producer who offered at £65 5s. per ton c.i.f., and this price has been accepted for a fair quantity of wire bars for February and March delivery. American shipments for January from the northern ports are advised as 30,967 tons. European stocks have decreased 1988 tons and a very large reduction in American refiners' stocks is expected. Imports are 3004 tons and deliveries 1545 tons less than during the same period last year. The total arrivals in England and France for the month have been 22,139 tons, and the deliveries 23,827 tons. Stocks have decreased 1688 tons, and the visible supply 1713 tons. The arrivals in England from Chile during the month have been 1628 and the deliveries 1359 tons, and from other countries 12,412 and 14,603 tons, respectively. The arrivals in Liverpool and in Swansea from the United States have been 2595 tons bars and 1763 tons plates; in London 732 and in France 7740 tons. The Chile charters for the month are advised as 3600 tons, including 1375 tons for the United States.

THE LEXINGTON MINE, owned by the La France company, in the Butte district, is to be operated again after having been closed for several years, and the ore is to be treated at the Basin Reduction Works, it is reported. A few months ago, when the works was taken from the State Savings Bank by New York interests, it was supposed that the persons furnishing the money were acting for W. A. Clark, as experts had made an inspection of the property for him; but it now transpires that the finances came from the La France people, or rather interests acting for that company. The Lexington was originally a silver property and had to be closed down on account of the low price of that metal. For several years it has been known that the mine has been rich in zinc, but after several tests had been made under different processes, none were found equal to treating the ore at a profit. However, some recent tests have clearly demonstrated that the ore can be handled at a good advantage, and, while no official information has yet reached this city, men who are very close to Heinze say that the Lexington is again to be operated, this time as a zinc proposition, and that tests made under a new process show that the ore can be treated at a profit of at least a dollar per ton. The La France company had this information a few months ago, when it was decided to redeem the Basin Reduction Works, and the mystery which surrounded the redemption is now explained.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

E. W. PARKER is in San Francisco.
ALBERT BURCH is in southern California.
HOWARD D. SMITH is expected from London.
H. W. TURNER is in San Francisco temporarily.
H. FOSTER BAIN has returned to San Francisco.
CHARLES JANIN has returned from Santa Barbara.
JAMES G. BERRYHILL was in San Francisco recently.
A. C. NEATCH was here recently and has gone to the southern oilfields.

WEBB SMITH was in San Francisco recently and has returned to Martell.

WALTER J. RADFORD has returned from South America and will make his headquarters at Denver.

A. D. MILES has opened an office as consulting engineer in the Traders' Bank building, Toronto, Canada.

TAKESHI KAWAMURA was in San Francisco and has gone to Arizona and Colorado to visit mines and mills.

W. M. KNOX sailed on the *Korea* on February 20 for Vladivostok, expecting to reach Nicolaievsk by April 1.

R. C. TROEGER is in charge of extensions of the Dellaphene adit for the Estella Mining Co., Keeler, California.

E. M. MCGARY is general superintendent for the Chosen Mining Co., operating in the Yeng Byen district of northern Korea.

T. C. CRAWFORD, president of the United Gold Mining & Milling Co., sailed from London for New York on February 17.

J. D. HUBBARD is designing a 600-ton cyanide plant for the Chosen Mining Co., of Korea; he is expected in California early in March.

R. VAN A. MILLS, recently professor of mining at the Pei-Yang University, Tientsin, has returned from China, and is now at Washington, D. C.

J. H. BATCHELLER has resigned from the employ of the Britannia Beach Mining & Smelting Co. and is now metallurgist for the Tomboy at Telluride.

JOHN T. REID has returned to Nevada after a short business trip to New York concerning the Nevada United Mining Co. and the Mines Development Co. of Nevada.

CHESTER B. ALLEN, manager for the United Gold Mining & Milling Co., has gone to New York. He expects to return to San Francisco about the middle of March.

WARREN D. SMITH, chief of the Philippine Bureau of Science, will spend several months in the United States, visiting Washington, Pittsburg, and the California oilfields. His address is care of C. F. Smith, 1715 Kendall avenue, Madison, Wisconsin.

SAMUEL S. ARENTZ, superintendent for the Nevada Douglas Copper Co. for the past four years, has been appointed general superintendent for the company and of the Nevada Copper Belt railroad, with headquarters at Ludwig, Nevada. ARCHIE J. OREM becomes superintendent for the Nevada Douglas Copper Company.

W. R. BASSICK, for seven years with the Bucyrus Co., during five of which he was Pacific Coast manager, resigned from that company the latter part of 1911, and since January 1, 1912, has been in charge of the commercial department of the Yuba Construction Co., 311 California street, as manager of sales.

Obituary

BENJAMIN F. PEARSON, of Halifax, N. S., died of kidney disease on January 31. Mr. Pearson, who was 56 years old, had been prominent in Nova Scotian politics, but is better known as a successful financier and promoter of industrial enterprises, including the Dominion Coal Co. and the Dominion Iron & Steel Co., his achievements extending to Mexico and South America as well.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

ASSESSMENT WORK ON MINING CLAIMS HELD IN COMMON— CONTIGUOUS CLAIMS

The annual assessment work, where several claims are held in common, may be done on one of the claims for all, or it may be done on adjacent patented land or even on public land, if the claims are contiguous and the work is for the benefit of all of them and tends to develop them all and facilitate the extraction of ore from them. But mining claims which touch each other only at a common corner are not contiguous within the rule authorizing the performance of assessment work for several contiguous claims on any one of them.

Annville Hydraulic & Draining Co. v. Code, 182 Federal, 205.

PATENT TO MINERAL LAND

When the right to a patent under the soldier's additional homestead law depends upon whether the land is agricultural or mineral, that question must be determined according to the conditions existing at the time when the applicant complies with all the requirements of the statute. If at such time the land is not known to be chiefly valuable for coal, the applicant acquires a right to a patent which will not be disturbed by any subsequent change in the conditions; but if upon such compliance, it is discovered that the land is valuable for coal, nothing that he subsequently may do will give him a right to a patent, because such land known to be of that character is not subject to acquisition under such law, but only under the coal-land law.

Leonard v. Lennox, 181 Federal, 760.

AUTHORITY OF PIT-BOSS—NOTICE OF DANGER AND PROMISE TO REPAIR

Where a pit-boss employed the miners and other operatives in a mine and had authority to discharge them, and had immediate charge of the actual underground operations, and where it was his duty either to remedy any defects and dangerous conditions, or to report it to the proper office or department within whose scope such work properly belonged, where any such defect or dangerous condition was called to his attention, notice to him of the dangerous condition of a cage is equivalent to notice to the company, and a miner giving him such notice has the right to rely on the promise of such pit-boss that he would fix it as soon as possible.

Poli v. Numa Block Coal Co., (Iowa) 127 Northwest-ern, 1105. October 1910.

OWNER OF MINERAL RIGHT BOUND TO PROTECT SURFACE

Where surface land is owned by one person, and the mineral below, with the right of extracting the same, is owned by another, the owner of the mineral right is bound to protect the surface, unless the right of destroying the surface has been expressly reserved in terms so plain as to admit of no doubt. This rule was applied where co-owners of a mining claim conveyed the surface by separate conveyances at different times, each deed reserving the mineral and the right of extracting the same, with a covenant not to excavate nearer to the surface than 20 ft. One deed contained a covenant on the part of the grantor to conduct the mining operations so as not to injure the surface rights conveyed, and so as to protect the surface for a depth of 20 ft. thereunder. The other deed contained a covenant that the grantor should leave 20 ft. below the surface of the ground for support, but expressly provided that the grantor did not obligate himself to support or maintain the surface by timber or otherwise. Neither deed absolved the grantors from the obligation, implied in the grant of the surface, so to conduct their mining operations that the surface should at all times be sustained.

Cartoon v. South Butte Mining Co., 181 Federal, 941.

Company Reports

NEW YORK & HONDURAS ROSARIO MINING COMPANY

This company, operating mines at San Juancito, Honduras, during the year ended September 30, 1911, made a net production of \$1,022,453, and the bullion sold amounted to \$972,319. Operating expense for the year was \$468,064, leaving a profit for the period covered by the report of \$554,389. The mill treated 35,813 tons of ore, producing a total of \$887,170. The ore yielded 1,395,136 oz. silver and 8103 oz. gold, against a production the previous year of 1,289,174 oz. silver and 10,621 oz. gold. The actual extraction was 84.93%. Despite unavoidable shut-downs, a daily average of 47.2 stamps dropping was maintained at the mill. Total labor and supply cost for the year amounted to ₡9.16 per ton, against ₡9.10 for the previous year. Higher labor cost, which was offset by savings in supplies and chemicals, was caused partly by increased repair work for the old mill. About 38,716 wet tons of ore was transported to the mill by the aerial tramway at a cost of ₡1.09 per ton, against a cost the previous year of ₡1.50 per ton. The maintenance of the surface department for the year cost ₡35,518, or a rate of ₡1.12 per ton of ore produced. The San Juancito power-plant was officially put in commission in January. It cost ₡220,476, of which ₡143,896 was spent during the year covered by the report. The figures include the cost of an additional water-supply known as the Aguacatal flume-line, which amounted to ₡19,896. Excavation for the new Rosario mill was started, and during the year ₡343,590 was spent for labor and supplies, not including machinery. The completion of the mill, about March 1912, will give the company, it is claimed, the distinction of dropping the heaviest batteries on the continent, 1800-lb. stamps. B. D. Davis is superintendent of construction. A topographical map of the property of the company has been made along lines of the United States Geological Survey by J. H. Sinclair. The ore reserves include 121,088 tons of ore blocked out averaging \$26.16 per ton, against 107,575 tons averaging \$25.30 for the previous year, and 340,000 tons of ore averaging \$15.50 per ton, which will be available when the new mill is started. The dividends paid during the year amounted to \$90,000, making a total to date of \$3,060,000. The capitalization of the company is \$1,500,000, and the surplus amounts to \$1,639,534, the assets of the company being valued at \$3,488,367.

MINERALS SEPARATION, LIMITED

The report of this company for 1910 shows that it has reached the profit-earning stage. The income during the year from royalties and treatment operations was £82,691. For depreciation of plant, and experimental expenses, the directors have written off £54,100, so that the company could proceed, from the beginning of 1911, without encumbrance. Litigation expense, amounting to £17,078, has been charged against the share premium reserve. The company has secured a contract with a large mine in South Africa, according to a statement by John Ballot, chairman of the annual meeting, and the subsidiary corporation in America has in prospect a number of profitable contracts. Mr. Ballot referred at length in his report to the action of James M. Hyde, who since his retirement from the Minerals Separation in February 1911 has used its process independently in Montana. Suit for infringement of patent has been filed against Mr. Hyde. Mr. Ballot also explained in detail the results of the Minerals Separation process as used by the Zinc Corporation at Broken Hill, and asserted that the latter company had substituted it for the Elmore vacuum process because it was cheaper and more effective in the treatment of the low-grade material and slime. A noteworthy feature of the report is the statement that all debentures have been retired. The Minerals Separation, Ltd., owns the Sulman-Picard-Ballot and other patents for concentration by flotation.

THE RATE OF BURNING OF FUSE AS INFLUENCED BY TEMPERATURE AND PRESSURE. By Walter O. Snelling and Willard C. Cope. Technical Paper 6, Bureau of Mines. 28 pp. Washington, D. C., 1912.

WESTERN PORTION OF TORBROOK IRON ORE DEPOSITS, ANNAPOLIS COUNTY, NOVA SCOTIA. By Howells Fréchet. Bull. No. 7, Canada Department of Mines. 20 pp., ill., map, insert. Ottawa, 1912.

TOLERANCE OF EUCALYPTUS FOR ALKALI, with partial reprint from Bulletin 196. By R. H. Longbridge. Bull. No. 225, College of Agriculture, University of California, Berkeley, California. 70 pp., ill. Sacramento, 1911.

THIRTY-SECOND ANNUAL REPORT of the Director of the United States Geological Survey to the Secretary of the Interior, for the fiscal year ended June 30, 1911. 151 pp., index, maps, inserts. Washington, D. C., 1911.

REPORT ON THE GEOLOGY AND MINERAL RESOURCES OF THE CHIBOUGAMAU REGION, QUEBEC. By E. R. Faribault, J. C. Gwillim, Alfred E. Barlow. 215 pp., ill., index, insert. Province of Quebec, Department of Colonization, Mines, and Fisheries. Quebec, Canada, 1911.

PETROLEUM AND NATURAL GAS. PART II. MINERAL FUELS. By M. J. Munn, C. H. Wegemann, E. G. Woodruff, and Robert Anderson. Bull. 471-A, U. S. Geol. Surv. Advance chapter from 'Contributions to Economic Geology, 1910'. 132 pp., maps, inserts. Washington, D. C., 1912.

INVESTIGATIONS OF EXPLOSIVES USED IN COAL MINES. By Clarence Hall, W. O. Snelling, and S. P. Howell, with a chapter on the natural gas used at Pittsburg, by G. A. Burrell, and an introduction by Charles E. Munroe. Bull. 15, Bureau of Mines. 197 pp., ill., index. Washington, D. C., 1912.

HISTORY AND STATUS OF MINING IN YAVAPAI COUNTY, ARIZONA. 23 pp., ill. Published by the Immigration Commissioner of Yavapai County, under the Supervision of the Committee on Mines and Mining of the Prescott Chamber of Commerce, Prescott, Arizona, December 1911. This pamphlet is the forerunner of other similar publications to be issued by Immigration Commissioners and civic bodies in other counties of the new state.

The Excelsior Airometer

The sale of compressed air for commercial use has attained enormous proportions in the past ten years. Especially is this true in the mining districts of Australia, Africa, and America. Yet there has never existed until now a satisfactory, practical, and reliable means of measuring the air thus sold. The general practice in selling compressed air to mines is to calculate the amount of air consumed from the number and size of the drills, hoists, and other machines operated. This method is inequitable, rarely correct, and productive of much dissatisfaction.

The Excelsior airometer is a simple, reliable, and accurate air meter, that has been developed to meet the growing need for such a device in connection with the increasing use of compressed air for mining and commercial purposes. It measures in cubic feet the amount of free air used in the cylinder consumption of compressed air. Simplicity, durability, and accuracy are the dominant features of the Excelsior airometer, it being guaranteed not to vary more than 3% from its original standard in five years. It is the only meter that automatically compensates for variations in pressure, that shows on its dial the exact amount of air that has passed through it, irrespective of pressures, and that does not require careful attention to keep in condition.

The airometer is built upon the principle that in the cylinder consumption of compressed air, the speed of the air passage is dependent upon the pressure, and that the number of cubic feet of free air used is in direct proportion to the speed the air body assumes when filling the cylinder. It consists of a series of turbines and deflecting discs, arranged alternately within a casing. The shaft upon which the turbines are mounted extends throughout the length of the meter, and is connected by worm gears with a series of decimated gears, which are connected to a series of decimal dials, from which the meter reading is taken.

The deflecting discs are stationary in the casing, and around the outer edge are bored a series of holes, which have their axial line at an angle of 45° across the axial line of the meter. Between the discs are compartments, where the turbines are mounted on the shaft. The vanes of these turbines are set so that they face the axial line of the orifices at right angles. The air is admitted to the meter, and passing through the orifices, impinges in turn on the vanes of all the turbines before passing out. A simple gear shift is attached to the dial of counter to be thrown in and out of engagement with the meter gear. This allows the operator to take an accurate record of the air passing through the meter in a minute, simply by throwing the dial into engagement for one minute and then throwing it out. The dial is kept in mesh with the meter gear by a spring in the front wall of the dial box. It is thrown out of engagement and locked by pushing in and turning the knurled button projecting from the rear of the dial box. The Excelsior airometer will measure the air passing through a supply pipe in exactly the same fashion that water, gas, or electricity is measured. Every cubic foot of air that is delivered to the purchaser must pass through the meter, is measured, and must be paid for, whether it is used to run hoists, operate drills, blow smoke, or is allowed to leak through faulty joints and connections. On the other hand, the purchaser has the assurance that he is getting a fair return for his money, and it behooves him to watch the air consumption in his mine and avoid wastes.

The airometer is attached and attended in the same fashion as a water meter, only requiring an occasional oiling. The meter reading is taken from a series of decimal dials, as on a gas meter. This reading can be taken weekly, monthly, or at any convenient period. When the dials have completed a full register, they automatically reset themselves and start over again. The capacities of the dials range from 10,000,000 cu. ft. on the smallest size to 1,000,000,000 cu. ft. on the largest size. A meter will pay for itself in a very short time, and thereafter will prove to be a safe, faithful, and economical guardian of the interests of both seller and buyer of compressed air.

TAXATION of ore reserves is proposed in a bill now before the legislature of Idaho. This might well be called, 'A Bill for an Act to Discourage Stability and Economy in Mining.'

WORK on the Panama canal is in steady progress, as is evidenced by the notable records in steam-shovel excavation that are now being made there. During January the excavation amounted to 2,441,441 cubic yards, or an average daily output of 101,594 cubic yards.

IMPORTS of copper into the United States have grown from 1,000,000 pounds in 1900 to 266,000,000 in 1911, while exports have grown from 338,000,000 to 787,000,000 pounds in the same period. The large imports into a country so preëminently an exporter are largely due to our superior facilities for smelting and refining.

A NOT UNCOMMON phenomenon in mines is the finding of no ore where it was confidently expected, to the discomfiture of the management and the decrease of profit. A pleasing example of the contrary is the Camp Bird mine, which, having altogether yielded \$22,785,000, of which approximately \$11,500,000 was profit, was thought to be near exhaustion in 1910. During that year new ore was discovered which yielded a profit of \$110,000 and in 1911 ore worth \$300,000 more was found. New finds during the past month have further extended the productive life of the mine, so that in a small way it bids fair to resemble the widow's curse. We hope it may.

WATER has long been a problem at Cripple Creek and, now that deep-level drainage is effectively secured, seems about to exhibit, to use an expressive phrase, 'reverse English.' Recent metallurgical development has led to the multiplication of mills in the district, and with their increase in number comes an increased demand for water, of which the supply is limited. Many suggestions have been made, among them that mills should be constructed underground. The objections to this are obvious, but the proposal cannot be instantly dismissed, for the plan offers advantages. Cripple Creek operators have handled their metallurgical problems admirably so far, and may be expected to continue to do so.

ELECTION of Mr. James F. Kemp as president and Mr. Waldemar Lindgren vice-president of the American Institute of Mining Engineers, marks not only the selection of eminently qualified men for distinguished posts, but is a deserved compliment to geologists as a class. It is striking that despite the large contributions to the work of the Institute made by the geologists, Mr. Kemp is the first to be elected president. In Canada, the engineers have not been so slow to divide honors with their professional brethren. Mr. Frank D. Adams, now president of the Canadian Mining Institute, is known mainly for his research in pure science. He succeeded Mr. W. G. Miller, the well known pioneer of Cobalt and the distinguished Provincial geologist of Ontario.

LITIGATION regarding filter patents entered another stage this week when the United States District Court decided, in the suit brought by the Moore Filter Company against the Tonopah-Belmont Development Company, that the Butters filter is not an infringement of the Moore, but that the stationary type of filters is distinctive from the movable type. An appeal is, however, to be taken, and since the Moore Filter Company controls the Cassel patents covering stationary types of filters, more litigation is sure to follow. It is one of the gravest defects of American patent law that there is no sure and simple method of quickly determining the relative rights of rival inventors. Metallurgical and other industries are, therefore, saddled with almost endless trouble and expense, and it often costs as much as it is worth to establish a patent right. The system is radically wrong, and a patent should mean more than "the right to go into court."

ECONOMY and efficiency are watch-words of modern practice, and in the use of fuels they are especially applicable. The work of Mr. W. A. Bone on combustion has attracted so much attention through his public lectures in this country that we are glad to present this week a brief summary of his conclusions. His methods and the results are none the less interesting for having been totally anticipated in this country by the work of Mr. C. E. Lucke, about ten years ago. It is a striking commentary upon the complexity of present-day life and the enormous volume of literature which must be scanned by advanced workers in science that not only Mr. Bone seems to have been unaware of the work of Mr. Lucke, which was published in the proceedings of the American Society of Mechanical Engineers and is discussed in Hutton's 'The Gas Engine,' but editors of American journals devoted to mechanical engineering seem to have been equally uninformed. The proposed methods are suggestive, and when their mechanical drawbacks are eliminated by sufficient experiment, are likely to prove valuable.

OUR special correspondent who attended the recent meeting of the American Institute of Mining Engineers in New York City writes in frank criticism of certain features of the past management of the Institute and of the dinner arranged by the local committee. It has seemed worth while to print this criticism even though it is abundantly clear, as stated in his letter, that a new management is in control. Such trouble as now encompasses the Institute has come mainly from failure to make publicly criticism common enough in private. The best thing that could happen to the Institute would be to have its great membership more alive to the duties as well as privileges of being included in its ranks. There are many different programs that may be followed in the conduct of such an organization, and critics of all classes will concede that brilliant success in certain directions has resulted from the faithful work of those who have been in control. Our understanding is that, with full appreciation of the good in the past, the members have decided that a change of program is in order. We have a profound belief in the continued usefulness of the Institute, and we feel that it is but following the order of development in other lines of contemporary American life for 'Staidpatters' to give way to 'Progressives' and for representative government to be replaced by the more democratic form that relies on the initiative, referendum, and recall.

RICH gold-quartz mines are not commonly thought of as characteristic of Alaska. The unusual success achieved in working the great low-grade orebodies near Juneau has drawn attention away from the possibility of

finding smaller and richer veins. But rich quartz is well known at Nome, Fairbanks, Valdez, and at various widely scattered points in the interior and in southeastern Alaska. At the Cliff mine, when it was visited last July, the ore going to the mill was averaging \$87 per ton in gold, and at the Klag bay properties, described in this issue by Mr. Adolph Knopf of the United States Geological Survey, specimen ore taken from the surface and transported to Sitka in canoes, paid for opening the mines. How many additional deposits of this sort await discovery, no man can say. The region is one where prospecting is particularly laborious, and attention has so far been mainly centred on other things. Supplementing Mr. Knopf's description of the DeGross mine, it is interesting to note that a considerable share in this property was one of the principal items in the estate of the late D. H. Jarvis, that brilliant and likeable captain whose untimely suicide last summer startled all who had followed his interesting career. The Golden Gate mine, we understand, has now passed into possession of the Chichagof Gold Mining Company, owner of the neighboring DeGross mine. The prospect for a fairly large as well as rich mine seems excellent, and success here should stimulate the search for more mines in the great replica of the California goldfields in which the channels and passages of the Inland sea have been cut.

San Francisco and the Mint

Proposals to so reduce the appropriation as practically, if not nominally, to close the mint at San Francisco, have aroused a not unnatural storm of protest throughout the West. The San Francisco mint was established in 1854 and has coined \$1,672,000,000 in gold, and \$185,000,000 in silver. In addition \$74,000,000 has been coined for circulation in the Philippine Islands and considerable amounts of silver and gold for Central American and other countries. The mint has been the centre of the trade in gold and silver on the coast, and the money in the vaults proved the salvation of San Francisco in the time of its greatest distress in 1906. Sentiment clings strongly to the old stone building on Mission street and any plan for converting it into a mere assay office arouses deep-seated feelings. The proposal is made, nominally, in the interest of economy, and certainly that is a proper plea. It is no sufficient excuse for maintaining a government institution, be it navy yard, branch pension office, or mint, that it leads to spending money in a particular city or district. Public convenience and real service should be the basis of maintenance as well as establishment of government works. Legislation enacted at the last session of Congress and permitting the stamping of gold bars with weight and fineness in place of minting money for export, has reduced the demands upon the Bureau of the Mint and permits reduction of its force, as was expected. This is right and proper and in the interest of economy. The critical point is, where the reduction should be made. To this we believe there can be but one answer. The Director of the Mint should be director in fact as well as name. If the full value of his services is to be obtained, he should be permitted to conduct the service as seems to him best. If he proves wrong, remove him and get a better man, but do not hamper him in the exercise of his duties. Believing in this as a general principle, and knowing, further, that in Mr. George Roberts the Bureau has a most capable director, we urge that his recommendations be accepted. Meddling with technical matters by committees from Congress is all wrong. Congressmen are subjected to political pressure from every side and determinations made by them in matters relating to the internal organization of a bureau, or the conduct of its work, are necessarily based upon compromise rather than upon principles of

efficiency in operation. It is said, for example, that in this case the proposal to close the San Francisco mint is in retaliation for the closing of that at New Orleans and the decision to hold the exposition of 1915 in San Francisco. Whether true or not, there should be no question as to such determination of the matter. It is generally believed that the mint at Denver was established less because of real need than to secure the spending of money in that city by the United States Government. The day when that sort of thing could go unchallenged has passed, we hope permanently, from America. Let technical matters be decided on the basis of real economy and efficiency, and not with a view to 'solidifying the party.'

The mint service is peculiar in that it is one of the branches of the Government that turns into the Treasury more than it receives in appropriations. In part, this is due to the profit in refining and melting bullion, and in part to the seigniorage on silver. In the West people generally prefer metallic money. Gold and silver coins are the common media of exchange, and so long as metallic money circulates it must be coined and re-coined. It would seem proper that the people who demand actual coinage of money should enjoy whatever of advantage may flow from the maintenance of a mint in their midst. Such arguments should not, however, determine the question. It is a business matter and should be settled on a business basis, and one of the best rules for the conduct of any business is, follow the lead of the responsible head of the enterprise.

Research and the Government

Much confusion of thought has been made evident by the discussion of various bills now before Congress in which it is proposed that the Government shall undertake researches connected with metallurgy. There are a number of bills similar to those of Mr. J. E. Raker of California and Mr. J. A. Martin of Colorado in which is proposed the establishment of local stations for ore testing. Others provide for establishment of additional mine-rescue stations. Still others propose appropriations in aid of state schools of mines on substantially the same basis as the Congressional aid now given to agricultural colleges. There is furthermore the Foster bill, now on the Union calendar, defining and extending the duties of the Bureau of Mines.

It can hardly be said that there is no public sentiment in favor of some such extension of governmental activity, and it seems inevitable that now or later steps in this direction will be taken. As conditions change and the need of help becomes greater, people everywhere demand more from their governments, and whether it be liked or not, government not only in the United States but in Canada, England, Germany, indeed throughout the world, is becoming increasingly paternal. Crowding people together results in more points of contact, and, human nature being what it is, more regulation of human relations must result. Government regulations to accomplish good must be informed, and of the harm done by uninformed action numerous instances might be readily cited. It is not only right and proper, but it is necessary, that the Government should itself have every facility for keeping in touch with the latest advances in technology as in other lines of human activity and on the basis of economy. United States laboratories and experiment stations are better than duplicate state plants. The states should have every facility, as is proposed in the Foster bill, for using the Government plant in determining such matters as the type of explosives that may be permitted in coal mines and the quality of those offered for use. The United States Government, too, should have the full benefit in all its branches of the best technical advice regarding the fuel that it buys, the cement it must use, and similar

matters. So far we believe there is no disagreement, and details of legislation necessary to give these principles effect may safely be left to Congress. Another phase of the matter, however, invites discussion.

Research may be conducted with a view to: (1) elucidating fundamental principles and promoting development of technology with a view to improvements in practice; (2) testing individual specimens or lots of ore to determine which among standard methods of treatment are applicable in each case. While there is a certain border zone between the two, in the main we think the distinction is sharp and easily maintained. Recognizing that there is room for differences of opinion, we believe the first to be a proper field for the United States Bureau of Mines and the second to be one best filled by private agencies. The time may come when, in order to curb the deplorable recklessness and dishonesty of certain types of so-called assayers and metallurgists, the state will have to set standards and exercise some control over the business, but we are not prepared at present for that step. In the main, assayers and chemists are honorable men and their charges are reasonable, and any one having ore or minerals of probable value can readily learn through the use of existing agencies whether the material can be treated at a profit by any of the common methods.

All processes necessarily involve waste, and at best it can only be hoped by successive improvements to reduce this to a minimum. The large Government holdings of mineral land, to say nothing of the general welfare, warrant a reasonable expenditure of official funds in the effort to decrease waste and increase efficiency in production. There are furthermore many problems relating to the health and safety of mine workers that demand investigation. The United States Bureau of Mines should be given sufficient authority and funds to carry on a reasonable amount of experimentation along all these lines. This is in the interest of economy and efficiency, and in line with the work of the more enlightened governments elsewhere, and of our own experience in other lines. The Dominion of Canada has appropriated money for investigation of zinc smelting problems, and much of the work has been carried on by Mr. W. R. Ingalls of New York. We see no reason why such work should not be equally proper and profitable in the United States, though in this as other matters duplication should be avoided. It is also advisable to avoid waste of funds by fixed requirements in the form of local stations. Give the Bureau of Mines general authority and such money as can be spared, and let the officers of that organization work along whatever lines seem most likely to produce results. We particularly deprecate the effort to establish more mine-rescue stations at Federal expense. Not that more such stations are not needed, but that experience has shown that the mine-rescue cars are more economical and serviceable in the particular part of this work that the Federal Government should take up; namely, the demonstration of the work, and the proving of methods. The cars will be available for any emergency, but the routine work of actual protection should rest on the states, districts, or mines actually benefited. Where so much is to be done it is a pity to have time and energy wasted in controversy over methods and limits. The Geological Survey and the Bureau of Standards have prospered and have given excellent service because they were not hampered by petty restrictions in their organic acts, but could turn attention at once to problems as they arose, as fast as Congress was able to supply the funds. The Reclamation Service has also been singularly free from such restrictions, and has made substantial returns for its freedom. Efficiency is needed in the Government service, and freedom from 'red tape' is only possible under broad laws dealing with principles rather than details.

Gold Deposits of the Sitka, Alaska, District

By ADOLPH KNOPP

*Klag bay is on the west coast of Chichagof island and is part of an extensive archipelago of which Khaz bay forms the entrance from the Pacific Ocean. The coast north of Khaz bay is flanked for several miles seaward by rocks, reefs, and low wooded islets. Khaz bay lies 16 miles northwest of Salisbury sound, and the voyage from the mines to Sitka necessitates a coastwise run of 8 to 12 miles in the open ocean. The total distance to Sitka is 50 miles, and the operating mines maintain their own gasoline boats. Freighters plying between Seattle and the southeastern Alaska bring in occasionally heavy machinery and supplies, and take out shipments of accumulated concentrate. During the winter the upper three miles of Klag bay is frozen over.

The two productive gold mines in the Sitka mining district are at the head of Klag bay. The high grade of the ore, which yields, as milled, from \$15 to \$90 per ton in gold, greatly exceeds that of the average value of the gold ore of southeastern Alaska, which in 1909 was \$2.78 per ton. This has naturally attracted considerable attention to the region, and has stimulated prospecting of the shores of the neighboring bays, inlets, and passages.

Gold was found at Klag bay by chance in the summer of 1905 by an Indian engaged in salmon fishing, who went ashore to obtain water from a small stream near the head of the bay. While stooping to drink he noticed gold in one of the numerous fragments of quartz in the bed of the stream. On further examination he found that the ore contained considerably more free gold, and soon thereafter the find was reported at Sitka. The aid of white men was enlisted and the cropping from which the quartz float was derived was quickly discovered. Claims were thereupon located in accordance with the mining laws, the original discoverer retaining one-fourth interest. A small stampede from Sitka ensued soon after, and a large number of claims were staked on both flanks of Doolth mountain in September 1905. Two properties, known as the Chichagof and Golden Gate mines, have been brought to the producing stage.

The general geology of the region at the head of Klag bay is exceedingly simple. The rocks consist essentially of thick, massive beds of graywacke interstratified with clay slates. The only igneous rocks are a few narrow dikes of diorite aplite. To the northeast these rocks are succeeded by a wide belt of greenstones (altered amygdaloidal basalts in part), calcareous schists, limestones, and lightly contorted black phyllites and amphibolitic schists. This belt of metamorphic rocks is succeeded inland by diorite, which appears at the coast 15 miles northwest of Klag bay and is exposed northward to Lisianski strait. The graywackes and slates are well exposed along the shores of the bay. As a rule they are not intimately interstratified, as is common among the graywacke-slate formations of the Juneau region, Prince William sound, and Kenai peninsula, but form alternating belts several hundred feet thick. The graywacke is by far the dominant rock and forms massive exposures that are hundreds of feet thick and are without discernible stratification. Some strata, as shown by absolutely continuous exposures along the shore-line, attain a thickness of 1400 ft., and thicknesses in excess of 3200 ft., in which perhaps a few narrow belts of slate are included, have been measured at the head of Klag bay. The strike of the rocks ranges from N.40°W. to N.50°W. and the dip is 70°S. Whether the massive beds of graywackes maintain their great thickness for considerable distances along the strike was not determined, but it is believed that they will be found to dovetail with lenses of slate. The basis of this surmise

is the fact that near the head of Ogden passage a marked lenticular interstratification of graywacke and slate was observed. The lenses of graywacke range from a few inches to several feet in thickness and swell and pinch abruptly. The rocks show a cleavage or fissility which is best displayed in the argillaceous members and is but poorly developed or absent in the graywackes. It coincides in direction with the stratification. Locally the slates show considerable plication, with tearing and kneading of thin intercalated strata, but no evidence was procured that folding on a more extensive scale has taken place.

The orebodies at the head of Klag bay consist of quartz veins occupying shear zones in graywacke. They coincide in strike and dip with the stratification and schistosity of the enclosing country rock. On account of the thick-bedded character of the graywacke, only the roughly schistose structure and not the stratification of the wall-rocks is, as a rule, determinable near the veins. The orebodies range in thickness from a few inches to 18 ft. or more; in the producing properties the average thickness is perhaps 5 or 6 ft.; in the prospects it is a few inches or at most a few feet. The gold is localized in short shoots. In some lodes the fissuring is continuous for considerable lengths, but the fissured zone is barren of quartz and consists of sheared triturated graywacke; in other veins the quartz is continuous, but the gold content absent. In the vicinity of the veins the graywacke has been reduced to a black, highly polished, and irregularly schistose or slaty condition. In the midst of the sheared rock there remain numerous lenses and horses of massive graywacke. In places the shear zone may be 30 ft. or more in width and correspondingly leanly mineralized.

The veins show a well-marked ribbon structure, which is emphasized by the fact that the individual ribbons of quartz are separated by thin slabs of black schistose graywacke. These partings range from mere filaments to slabs several inches thick. As the quartz breaks free and clean from them, they often deceptively appear to form the walls of the orebody, but when they are broken through, more ore is commonly found behind them. Slabs of the lode slack off across the orebody up to such apparent walls, but however regular and well defined these walls may appear to be, not much reliance can be placed on the presumption that they mark the limits of profitable ore. Where the partings of schistose graywacke become thick and numerous the orebody becomes a typical stringer lode, and a corresponding decrease in the grade of the ore takes place. In the ore-shoots, however, the veins consist practically of solid quartz.

The foregoing structural features of the orebodies suggest that from a principal level driven along the general trend of the shear zone numerous cross-cuts should be made into both the hanging wall and the foot-wall. Not only do the apparent walls prove unreliable guides concerning the orebodies, but it is conceivable that where large horses of graywacke occur in the shear zone, the vein may split and curve around the massive rock, and on resuming its general trend may follow a parallel course at a distance of some feet in either the foot-wall or the hanging wall of the original course.

The mineralogy of the ore is simple. The gangue is a milk-white quartz of drusy texture, with which a small amount of carbonate is associated. This weathers red on the dumps and is therefore plainly evident. In addition, the microscope shows that some albite occurs with the carbonate. The quartz carries a considerable number of fragments of slaty graywacke, which are found microscopically to be completely sericitized.

Pyrite is the most abundant metallic mineral; galena and free gold are the only other metallic minerals. The presence of galena with the pyrite indicates everywhere high

*Abstract from *Bull.* 504, U. S. Geol. Surv., "The Sitka Mining District."

gold content. The pyrite occurs not only in massive form, but as deeply striated cubes in the vein quartz and also as minute cubes in the neighboring wall-rock. Galena is relatively rare and is as a rule intergrown with pyrite; it does not occur in the wall-rocks. The gold is found both as isolated particles embedded in the quartz and as particles intergrown with the sulphides. The ores are fresh and show little evidence of oxidation, the unaltered sulphides extending practically to the surface—a fact undoubtedly due to the glacial abrasion that the region has undergone in the recent geologic past.

The Chichagof mine, usually known as the DeGroff mine, is now the property of the Chichagof Gold Mining Co. It is situated at tidewater at the head of Klag bay (see Fig. 1). The milling plant in operation during 1910 consisted of two batteries of two 850-lb. stamps, dropping 104 times per minute in triple-discharge mortars. The ore was crushed to $\frac{1}{4}$ -in. mesh, and the pulp passed to a 10-ft. Chilean mill. The concentrating equipment includes a classifier, two Wilfley tables, and one Wilfley slime-table. The capacity of the mill was 20 tons per day. At present the tailing, which averages nearly \$10 per ton, is impounded for future cyanidation. Electric power is employed, which is transmitted $4\frac{1}{2}$ miles from the generating station on Sister lake. The hydro-electric plant and transmission line are under the control of a company jointly owned by the Chichagof Gold Mining Co. and the Golden Gate Mining Co., both of which it supplies with power. The plant is rated at 150 hp. and is driven by a turbine under 44 lb. pressure. In summer enough water is available to develop several times this power, but the capacity of the plant is fixed by the minimum winter flow. In the summer of 1910, because of increased development of the mine and the inefficiency of the Chilean mill, it was decided to erect a new mill of standard design equipped with 10 stamps of heavier pattern.

The orebody was found in 1905, as already related, by tracing to its source the quartz float so abundantly strewn in the bed of the small stream. The vein did not outcrop along the shore, but was found in place one-quarter of a mile inland, at an elevation of 275 ft. At the outcrop the vein ranged from 2 to 4 ft. in width. The float ore was carefully gathered and shipped to the smelter at Tacoma. This ore was rich enough to yield between \$15,000 and \$20,000. The proceeds were applied to development work, and the mine has paid its own way from the start. An adit 220 ft. long was driven on the vein and two ore-shoots were found, the second of which was 18 ft. wide at a maximum and averaged \$63 per ton across this width. Later a second adit was driven 162 ft. vertically beneath the upper adit, starting behind the mill, which is situated at the beach. Ore was found at 800 ft. from the portal, apparently belonging to the bottom of the first ore-shoot. A raise was put through to the upper level, and the ore thus developed is now being stoped. Unexpectedly it was found that the ore-shoot had a considerably greater strike length in the intermediate levels than was indicated on either the upper or lower adit levels. In addition to this encouraging feature, the ore-shoot maintained its width and remarkably high average value. Meanwhile development was vigorously continued on the lower adit in order to undercut the second ore-shoot.

The geologic features at the mine are simple. The bed-rock at the discovery outcrop is glaciated and covered with several feet of glacial drift containing striated blocks and cobbles of graywacke and some of diorite. The country rock inclosing the orebody is a nearly massive graywacke of dark blue-gray color and dense texture. It proves to be exceedingly hard and tough under the drill. In the main adit some thin beds of slaty argillite were found 200 ft. from the portal and show that the stratification trends N.55°W. and dips 70°SW., conforming to the general strike of the rocks at Klag bay.

Near the vein the graywacke has been powerfully sheared and has been transformed to a black, brilliantly lustrous, schistose rock resembling a polished and slickensided slate. The strike of the shear zone along which the ore makes

is approximately N.45°W., and its dip is 70°SW. Rich ore is limited to short shoots, but on account of the youth of the mine the shape of the shoots is not well known. It is a fair inference from the data at hand, however, that they are lenticular in both strike and dip. The vein shows in places a pronounced ribbon structure and is traversed by numerous false walls. Some of these walls are remarkably well developed, and it might often be thought unlikely that ore would be found behind them.

On the main adit-level a spur vein was found making out into the foot-wall country rock at an angle of 30° to the main orebody. It was about 8 ft. thick, but pinched out at the end of 75 ft. The rock included in the angle between the main vein and the spur is more or less shattered and penetrated by quartz stringers and impregnated with pyrite. The metallic minerals in the ore are pyrite,

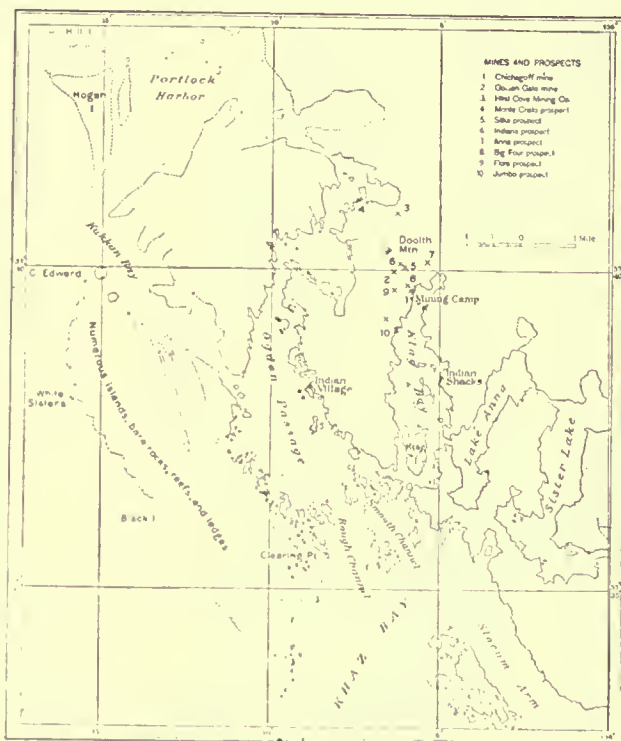

FIG. 1. PROSPECTS AT KLAG BAY.

which is by far the most abundant, galena, and free gold. According to the mill returns, the sulphides constitute from 2 to 3% of the ore.

The Golden Gate property, which is often referred to as the Mills property, one of the principal owners being W. P. Mills, of Sitka, is situated on what is undoubtedly the northwest extension of the Chichagof vein. The main haulage adit is situated at an altitude of 1000 ft. and is connected by an aerial tramway with the stamp-mill on the beach. The mill is of 10-stamp capacity, but only five stamps were installed at the time the mill was started in 1910.

The original discovery was made in September 1905 on an outcrop exposed at an altitude of 1520 ft. Great slabs of the vein lie scattered on the mountain side, many over a hundred feet from their position in place. Some of these slabs are 10 to 15 ft. long, 5 ft. or more wide, and several feet thick. The vein is 10 ft. thick at the discovery cropping, where a spur vein making a narrow angle with the main vein extends 300 ft. into the hanging-wall country rock. A shoot of richer ore was later discovered lower on the mountain, and the development work has so far been directed toward exploring this ore. An adit at an altitude of 1080 ft. was driven on the vein and undercuts the ore-shoot at a maximum depth of 127 ft. Subsequently a new adit, 80 ft. below the older, was driven, and forms the main haulage-way of the mine.

Surveys indicate that the Golden Gate and Chichagof mines are situated on the same vein, but actual continuity cannot be traced on the surface, either because glacial drift

and vegetation cover the apex of the vein or because the shear zone is barren of quartz mineralization along the intervening stretch. Either condition is equally probable. The geologic and mineralogic features of the orebody are similar to those of the Chichagof. The average width of the explored portion of the orebody is somewhat smaller, and the grade of ore is lower, although it was reported late in June 1910 that a shoot of a richness comparable to that of the older property had been found.

On the surface 150 ft. in the foot-wall of the vein is a dike, which is 100 ft. wide at its widest point. It trends parallel with the formation and can be traced a few hundred feet only. On the hanging-wall side the dike consists of a white coarsely granitoid rock, which the microscope shows is composed essentially of quartz and albite in hypidiomorphic arrangement, but much crushed. Toward the foot-wall the dike changes, apparently by gradation, into a rock resembling a greenstone. The microscope shows that this green rock formerly consisted of a coarsely granular assemblage of plagioclase, probably albite, hornblende, and biotite, but that it now consists of brecciated fragments embedded in a fine-grained matrix of attrition products composed of hornblende, chlorite, and feldspar.

The Hirst Cove property is situated on the northwest side of Doolth mountain. An adit 800 ft. long is driven on the vein at 400 ft. altitude, at a point one-half mile inland from Mine cove. The vein averages 3 ft. in thickness, and the ore resembles that of the Chichagof and Golden Gate mines, though metallic minerals are materially less abundant and are usually concentrated in the slaty material inclosed in the vein quartz. Some pay-streaks remarkably rich in free gold have been found. The vein is sometimes considered the northwestern extension of the Chichagof vein on the southeast side of Doolth mountain, but it lies too far to the northeast—that is, in the foot-wall of the Chichagof vein—to be the extension of that orebody.

A considerable number of prospects, such as the Monte Cristo, Flora, Jumbo, Big Four, and others, have been located in the region around Klag bay. The amount of development is generally small, and as the geologic features are entirely similar to the orebodies already described, individual descriptions are hardly necessary. The presence of these prospects indicates that mineralization is widespread throughout the region. The showing at the various prospects is commonly not impressive, but it must be confessed that if only the barren portion of the shear zone of the most productive mine of Klag bay were known, it would hardly present a more encouraging appearance than that shown by the poorest prospect in the region.

The Princess Pinder prospect is not on the peninsula between Klag bay and Ogden passage, as are the others previously described, but is near the entrance of a bay locally known as Piinta bay, six or eight miles northwest of Mine cove. Ore was discovered here in June 1910 outcropping in the cliffs at the water's edge along a shoreline that had been more or less thoroughly examined by various prospectors. This fact is of some interest and leads to the belief that the shore-lines have not been so carefully examined but that other prospects will be discovered. The orebody shows a face of 7 ft. of coarse white quartz carrying some scattered bunches of pyrrhotite admixed with chalcopyrite. The trend of the deposit is probably $S.40^{\circ}E.$ (true), and the dip is $80^{\circ}SW.$ The foot-wall is a blue-black slaty rock and the hanging wall is a greenstone breccia. Assays of samples taken across the entire width of the vein show an average value of \$10 per ton in gold.

The rocks in the vicinity of Sitka are mainly graywackes and slates striking $N.70^{\circ}W.$ and dipping steeply to the south. Some fine-grained quartzites, in places so extremely fine grained as to resemble light greenish cherts, are associated with them at various localities. Igneous rocks are rare. A few dikes of diorite aplite cut the graywackes and slates. One of these dikes has been found to be mineralized and to carry free gold. A crushed dike of dark gabbro, somewhat impregnated with pyrite and pyrrhotite,

is exposed on the northeast side of Bear bay, an indentation of Silver bay. The rock consists essentially of plagioclase feldspar, near bytownite in composition, and hornblende, probably secondary. At Bear lake, east of the bay of the same name, quartz diorite occurs. It is a medium-grained granitic rock composed of plagioclase, quartz, hornblende, and biotite, and is of uniform grain, color, and appearance. The diorite is somewhat gneissic and banded near its contact with the sedimentary rocks, which appear to have been considerably altered as a result of the intrusion.

The orebodies occupy shear zones in graywacke and strike parallel to the stratification of the country rock. The dips are steep—nearly vertical. The lodes form massive outcrops of white quartz up to 15 ft. or more in thickness which are apt to show a short lenticular structure along the strike and to split up into stringer veins. They are irregular in shape, bellying out and constricting abruptly. Near the veins the country rock is much sheared and is penetrated by numerous transverse stringers, as well as by veins parallel to the shear planes. A characteristic feature

FIG. 2. PROSPECTS NEAR SILVER BAY.

of the orebodies is the insignificant amount of metallic sulphides—in many veins an almost negligible quantity—contained in the vein quartz. Pyrite, pyrrhotite, and arsenopyrite are the principal sulphides; galena and sphalerite have been observed, but are extremely rare. The sulphides are at many places concentrated in and around fragments of slate or sheared graywacke included in the veins, even though the quartz itself is barren. Orebodies of a type different from the auriferous quartz veins already described have attracted some attention. These consist of beds of shattered quartzite, which is flintlike in texture, recemented by quartz veinlets, carrying in places, though rarely, pyrrhotite and arsenopyrite. Some quartzite strata weather so that the surface exposures somewhat resemble vein quartz, but the mineralization is so feeble that it is difficult to understand why they should have been located as orebodies.

The Cache mine, located in October 1872, and originally known as the Stewart mine, is situated $1\frac{1}{4}$ miles east of the head of Silver bay, at an elevation of 720 ft. above sea-level (see Fig. 2). A 10-stamp mill was built in 1879, but has long ago fallen into ruins, and the tramways leading to it are thicketed with new growth of alders. The mine has been in litigation for many years. The orebody, which is nearly vertical, is opened on three levels by adits aggregating 300 ft. in length. The lowest adit is 160 ft. long and trends $S.70^{\circ}E.$; at the month the orebody is 4

ft. thick and increases to a maximum of 13 ft. solid quartz, its average thickness being about 10 ft. The walls of the orebody are extremely curved, dipping in reverse directions from place to place. Practically no metallic sulphides are visible in the quartz, except a streak on the south wall, which is fairly mineralized with pyrite. The other two tunnels, the upper being about 80 ft. above the lower, show essentially the same features, but not so much quartz.

The Bauer mine lies 2 miles southwest of the head of Silver bay. The main development consists of an adit at an altitude of 1250 ft. This adit, which is 900 ft. long and intersects the main orebody at a depth of 400 ft., traverses thick massive beds of graywacke, which are gritty or conglomeratic at the portal, and crosses several smaller veins striking parallel with the formation. At the end a drift 150 ft. long is turned off on the orebody and trends S.45°E. The hanging wall is slate and the foot-wall is graywacke. The orebody consists of cryptocrystalline quartzite traversed by narrow quartz veinlets and leanly mineralized with pyrrhotite.

The Cascade claim is on the east fork of Indian river, 3 miles from Sitka, and is the only one discovered in the vicinity of Sitka or Silver bay in recent years. The country rock at this locality consists of cherty quartzite and slate striking N.55°W. and dipping approximately vertical. The quartzite, which is flintlike in texture, weathers milk white, so that it resembles a quartz lode. The orebody consists of shattered quartzite cemented by quartz veinlets and is in places mineralized with pyrrhotite and arsenopyrite. Chalcopyrite is present as an extremely rare constituent. A 5-ft. bed of slate appears to form the wall-rock on the southwest side of the orebody, but toward the northeast the boundary is indefinite. The orebody is exposed by open-cutting and is 300 ft. long. Its width apparently ranges from 4 to 20 ft., but these dimensions will doubtless be dependent upon assay returns.

The Lucky Chance mine is situated in a precipitous mountain range, 2000 ft. above sea-level and 4 miles as the crow flies, or 7 by wagon-road, from the head of Silver bay. The quartz vein has a maximum width of 8 ft. where it outcrops, but in the adit it is not constant in width and appears to merge into a series of narrow stringers penetrating the mineralized slate hanging wall. The foot-wall, of graywacke, is locally known as diorite because of its compact, massive structure. A 600-ft. adit follows the vein and connects through a raise with a surface pit. The surface improvements comprise a 10-stamp mill, a sawmill, and a water-power plant. High assays are reported from parts of this vein and many specimens of free gold have been obtained.

Many other prospects, partly developed, notably the Lower Ledge, Bullion, Free Gold, Liberty Lode, Silver Bay group, and the Boston, are still held in this area, some of which have very favorable surface showings, but lack of capital and inefficient management have caused a suspension of explorations for the last few years.

The Caisson Disease

By WALTER PEET

Compressed-air illness or caisson disease, has been recognized for many years, but it remained for Paul Bert, a French physiologist, to discover the exact cause. He worked the whole matter out theoretically, and then proved it practically by experiments on animals. Normally we live under a pressure of atmosphere of approximately 15 lb. to the square inch, and at this pressure a certain amount of gas goes into solution in the fluids of the body (and the human organism is three-quarters liquid), as it would dissolve in any other fluid. The air is not a chemical compound but a mechanical mixture. Leaving out of consideration about 0.4 to 0.5% of other gases, it consists of about 24 parts of oxygen and 79 parts of nitrogen by volume. When a man or animal goes into compressed air the blood takes into solution an increased quantity of oxygen and nitrogen from this compressed atmosphere, the

quantity of these gases absorbed being in direct proportion to the increase in the pressure. These gases taken up by the blood at the lungs are gradually distributed throughout the body. When a man suddenly comes up into the normal atmosphere, as he usually does after work, the abnormal pressure is taken off and he undergoes rapid 'de-compression.' When the pressure is released, the nitrogen gas, which had been held in solution by the pressure, forms in little bubbles in the blood. This is the cause of the whole trouble. These bubbles act as emboli (obstructions) and block up the capillaries (little blood vessels) in one or another part of the body, and, by thus cutting off the blood supply or by direct mechanical violence, cause the various symptoms of compressed-air illness. The harmful results, which take place only after the patient goes into normal air, where the extra pressure is taken off the nitrogen, may be prevented by making the change from the highly compressed atmosphere slow enough to allow the absorbed nitrogen to escape by the lungs.—Harper's Weekly.

Surface Combustion

By RAYMOND C. BENNER

The fundamental principle underlying surface combustion, which has been extensively studied by W. A. Bone, is that all hot surfaces accelerate chemical changes in gaseous systems. In the case of electrolytic gas enclosed in smooth glass walls, say at 450°C ., a negligible amount of steam may be formed. Certainly, this may be said to be the tendency there. By placing in this vessel some porous substance, so that a much larger surface is exposed to the gas, chemical union is caused to take place at a measurable rate at the surface, not rapidly enough, however, to cause an explosion. It is therefore necessary to distinguish between two possible conditions under which gaseous combustion may occur: (1) Homogeneously—that is to say, equally throughout the system as a whole, at temperatures below the ignition point, slowly and without flame, and at temperatures above the ignition point rapidly and with flame; (2) heterogeneously, or only in layers immediately in contact with an incandescent surface. The latter is surface combustion and the process is much more rapid than is the normal combustion in ordinary flames.

The fact that metals of the platinum group aid in the chemical union of gases has long been known, but that hot surfaces in general have this acceleratory influence on gaseous combustion has, in all probability, escaped recognition of technologists because of the idea possessed by Siemens, that combustion was retarded by hot surfaces. Before Siemens' time this subject seems to have received the attention of a number of men such as Döbereiner, Davy, and others, but with no explanation of the phenomena or practical results other than Döbereiner's lamp.

The fact that all surfaces, depending on their chemical and physical properties, accelerate combustion at temperatures below the ignition point, is not the only point to be considered. Treatment in various manners can change the rate greatly. For example, if a surface consisting of a non-oxidizable metal or non-reducible oxide be exposed to H or CO before use, its action in bringing about their union with O is greatly stimulated. If previously exposed to O the rate of combustion is decreased. The relative affinities of different substances for O in ordinary combustion may be changed in the presence of hot surfaces; under ordinary conditions O has a greater affinity for CH_4 than for H or CO. This is reversed in the presence of a hot surface. H_2O is probably essential to the burning of CO under ordinary conditions, but it has been shown to greatly retard surface combustion.

Mr. Bone's experimental work leads him to believe that the accelerating power of surfaces increases with temperature; and the difference which different bodies show in the rates of acceleration tends to disappear with increase of temperature. When explosive mixtures of gases are forced through incandescent porous substances, the rate of combustion is so greatly hastened that combustion takes place within the pores at a rapid rate. Therefore the surface of the porous diaphragm is kept in a state of incandescence without flame. The two chief points here emphasized are, that the term 'pore' is not used in the gross sense, but in that of molecular dimensions, and that the incandescent surface plays a truly important part in inciting chemical action.

The advantages claimed for surface combustion are: (1) Great concentration of heat in a small space, because of the greatly increased rapidity of combustion; (2) combustion takes place without excess of air, thus doing away with one great loss of heat essential to ordinary combustion operations; (3) temperatures, due to the foregoing reasons, are higher than otherwise possible without regenerative devices; (4) the large amount of radiant energy developed makes the transference of heat much more rapid. The heating diaphragm, shown in Fig. 1, is made of granules of fire brick bound together with a suitable material. This diaphragm, the structure of which is readily seen in the

figure, is quite porous, so much so that $\frac{1}{8}$ -in. water pressure readily forces air through it. The air and gas are supplied to the mixing chamber 'A' either by means of a Y-tube and low pressure (2 to 3 in. water) gas and air or by means of an injector, by the use of which gas can be supplied at two pounds pressure.

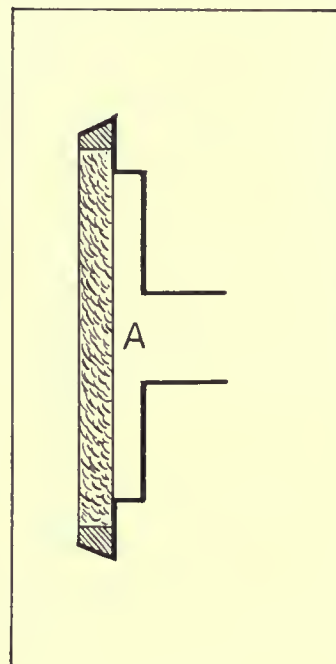

FIG. 1.

In starting, the gas is admitted alone and ignited, after which the air is turned on gradually. The flame becomes non-luminous and smaller in size until the correct percentage of air and gas is being used, when it disappears and only an intensely hot surface without flame remains. But a thin surface layer of the diaphragm becomes hot ($\frac{1}{8}$ to $\frac{1}{4}$ in.), while the back of the apparatus remains cool enough to touch with the hand. Unburned gases do not escape from the surface and the temperature rises immediately upon increasing the supply of gas.

Temperatures up to 850°C . are easily maintained on a freely radiating surface. The diaphragm can be used equally well in any position and with any of the ordinary forms of fuel gases, the amount of heat generated depending, of course, upon the kind of gas used. The gas surrounding the incandescent surface has no effect whatsoever upon the combustion; in an atmosphere of CO_2 the diaphragm acts as well as in air.

An interesting experiment, showing one of many applications to which this method of heating can be applied, is the evaporation of sodium silicate solution by placing the diaphragm above the dish containing the solution, so that the upper layers of the solution are heated by radiant heat. As evaporation takes place the dry silicate can be skimmed off. This method is much easier and more satisfactory than trying to evaporate a solution of this nature by heating from below.

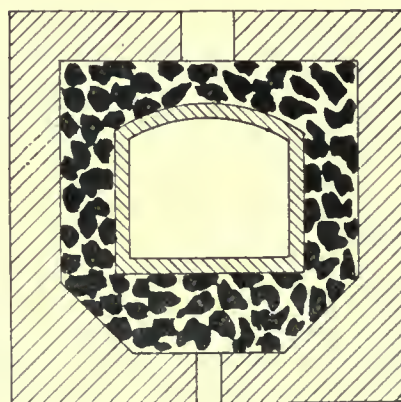

FIG. 2.

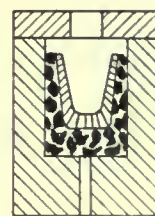

FIG. 3.

The second application of the process can be used equally well for gases and vapors. Fig. 2 and 3 make the explanation simple. The explosive mixture of air and gas is forced through an orifice in the base of either a muffle or a crucible furnace at a rate more rapid than that of back firing. The combustion takes place in the bed of granular refractory material, no flame coming out of the top of the furnace. The intensity of the temperature obtainable may almost be said to be limited only by the fusibility of the refractories. These furnaces are started in the same way as the dia-

phragm, but at the expense of more time. The following table shows the great efficiency of this arrangement, when it is remembered that in order to maintain a muffle of similar size and shape at 1055°C., 105 cu. ft. of gas per hour is required, when the muffle is heated by the ordinary method employed in gas furnaces.

RESULTS OF TEST ON A MUFFLE FURNACE					
(Dimensions of muffle, 9½ by 5¼ by ¾ in.)					
Temp. middle of muffle:		Gas consumption to maintain temp. constant, cu. ft. per hr. at 15°C.	Temp. of products:		
°C.	°F.		°C.	°F.	
815	1409	21.0	540	1004	
1004	1840	35.3	645	1195	
1205	2201	58.0	870	1598	
1424	2596	79.0	1085	1985	

Mean net cal. val. of gas, 540 b.t.u. per cu. ft., at 15°C.

The application of the principles of surface combustion to steam-boilers becomes of great interest, remembering that the average thermal efficiency of gas-fired boilers is not far from 65% and that nearly 95% efficiency has been obtained by the new method. The arrangement used with a small boiler of cylindrical section three feet in length traversed by tubes three inches in diameter is simple. The whole length of the tubes is packed with granular refractory material of the proper size, the front end fitted with a clay plug, containing an opening of such size that the speed of entering explosive mixture will be greater than that of back firing, each tube communicating with a mixing chamber of especial design. The products of combustion leave the boiler at not more than 70°C. above the temperature of the water in the boiler and pass through a feed-water heater, which they leave with a temperature of less than 100°C. The details of the experiment with a 10-tube boiler bring out the advantages possessed by this system:

- Pressure of gas and air, 17.3 in. (water gauge).
 - Steam pressure, 100 lb.
 - Products of combustion leaving boiler, 230°C.
 - Products of combustion leaving feed-water heater, 95°C.
 - Water entering feed-water heater, 5.5°C.
 - Water entering boiler, 58°C.
 - 996 cu. ft. of gas of 562 b.t.u. per cubic foot.
 - 559,800 total b.t.u. of gas.
 - 527,800 b.t.u. used in heating water.
 - 94.3% of total heat generated used in evaporating water.
- The advantages of this system of combustion when applied to boilers may be briefly summarized as follows:

- (1) Little if any excess of air is necessary to obtain perfect combustion; (2) with 0.5% oxygen in the products of combustion, combustion was complete; (3) steep heat gradient; (4) 70% of the evaporation occurs in the first third of the tube, 22% over the second third, and only 8% over the last third; (5) the mean evaporation is very high, over 20 lb. of water per square foot of heating surface; (6) while evaporating 20 lb. of water with an efficiency of nearly 95%, the equipment can be forced 50% higher with but little loss in efficiency.

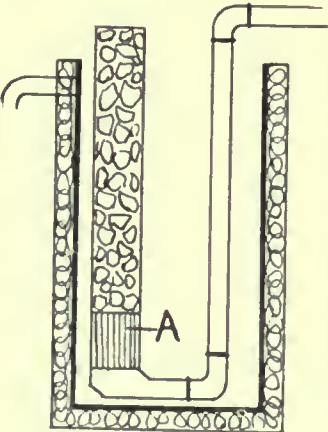

Fig. 4.

fractory material. There the combustion takes place in a

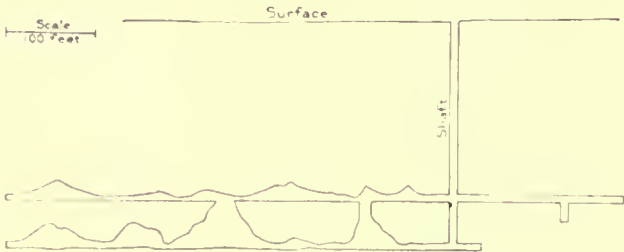

manner entirely similar to that described for the crucible and muffle furnaces. The following table gives a good idea of the efficiency of this process when applied in this way:

LEAD-MELTING TEST			°C.	°F.
Temperature of metal charged			15	60
Temperature of metal tapped			372	682
Temperature of gases leaving apparatus			500	932
Lead melted per hour, 1176 lb.				
Heat required per hour to raise metal from 15°C. to 372° (1176 by 32.57), 38,420 b.t.u.				
Gas burned per hour, 100 cu. ft. at normal temperature and pressure.				
Net cal. val. of gas, 559 b.t.u. per cu. ft. at normal temperature and pressure.				
Ratio, 38.42:55.90 = 0.686.				

Ore Not In Sight

By H. FOSTER BAIN

Measuring ore reserves is a work that calls for much common sense as well as experience. Many mistakes have been made by assuming ground to be ore-bearing that afterward proved to be barren. The safest and most generally accepted plan is to regard as 'positive' ore only that which has been exposed on four sides. Even this rule, however, fails in places. In the figure below is sketched a case in

point observed some years since in a small zinc mine at Dubuque, Iowa. The stopes indicated were all in zinc ore of good grade, as was also the bottom of the lower drift and the sides and ends of the drifts on which stoping had been done. Old shallow pits were known at the surface along the vein. A Western engineer examining such a property might easily be led to assume an ore-shoot about 450 ft. long, and a considerable amount of ore as actually 'in sight.' As a matter of fact, neither assumption is correct. The Dubuque orebodies at upper levels are developed where vertical crevices cross favorable flat-lying beds of dolomite. Along these horizontal intersections the ores have been formed as crusts on the walls of what are known as 'openings.' Little work, usually, is necessary to convert an opening into a level and where minor quartering crevices cross the main fracture vertical shoots or chimneys connect one such level with another. It is easy under such circumstances to get a mine in such shape as to readily deceive a stranger, though to the credit of the local mining men it is fair to say that I never knew of it being purposely done. Several Western 'practical' men have at various times insisted on deceiving themselves in this manner, and I remember yet the comical half-convinced look on the face of one such when I explained the true situation to him and reduced his ore reserve by a few hundred thousand tons. Mining in the Upper Mississippi Valley is now almost entirely in lower lying beds where the mode of occurrence is different from the one sketched above. It is sufficiently peculiar itself, but not quite so deceptive. Even in these lower beds, however, serious mistakes have been made and absurd estimates published. The characteristic occurrence is a series of outward dipping fracture planes known as 'pitches' and surrounding a 'core' of rock. Part of this interior core is usually mineralized and much of it is now worked. It is easy to convert optimism into figures and determine a large tonnage as 'in sight.' It is sometimes much harder, however, to find the ore called for by these estimates. It all enforces the necessity of knowing the local geology when making an examination.

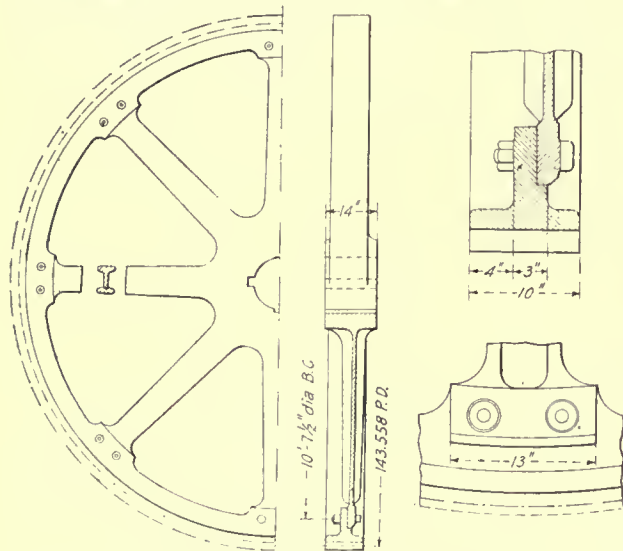

Mechanical Features of the California Gold-Dredge—II

By ROBERT E. CRANSTON

***BUCKET DRIVE.**—The buckets are driven by a chain of gears mounted on the main gantry. The use of a chain or shaft drive from the lower deck has now been entirely abandoned in California practice. Some dredges drive direct from the digging motor to the pulley shaft on the main gantry. Others use a countershaft on the main deck, from which also is driven the ladder hoist. Neither type has any great advantage over the other, and if properly designed either method will give satisfactory results.

The upper tumbler may be driven by a gear at one end of the tumbler shaft, or one at each end, with a double set of intermediate pinions, gears, and pulley-shaft pinions. The single drive is, of course, cheaper and simpler, but experience has shown that after many years of service the single drive is inclined to get out of line, even when very solidly built. I very much favor the double drive and would advise its use.

Bull Wheel.—The bull wheels or tumbler-shaft gears are

BULL-WHEEL, 9-CU. FT. DREDGE.

cast of steel in sections, sometimes with a split and sometimes with a solid hub. The rim is cast in one piece or in halves. Some designers use cut teeth, others rough cast. There can be no doubt but that the cut teeth run more smoothly, but for the rough work in hand I do not believe that the extra cost is warranted, particularly since the teeth are soon worn down and the benefit of the cut teeth disappears. In order to prevent breaking, all sharp angles should be avoided in the design of the spokes. They are subjected to constant shocks and vibration, and the gears will invariably break at a sharp re-entrant angle should such occur at a vulnerable point. In order to make a snug fit and also to keep the rim from becoming elliptical, the spokes should either have a shoulder fitting on a machined inner edge of the rim, or the ends of the spokes should be turned to fit a machined shoulder on the rim. The latter method is preferable, since it does away with sharp corners which, as explained above, are always points of weakness. It has been common practice to use one large bolt to fasten each spoke to the rim. Two smaller bolts are better, since a more even distribution of spoke cross-section can be maintained by this design and it gives a longer spoke end to bear against the machined rim. A good many spokes have been broken near the rim where the cross-section is ample but where a point of weakness exists owing to the re-entrant shoulder above mentioned.

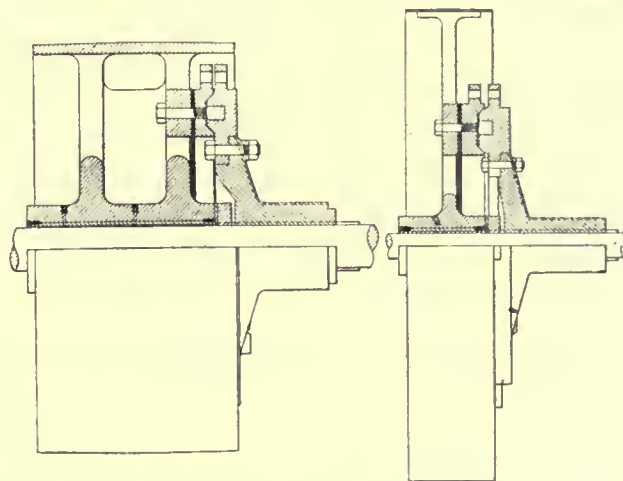

Intermediate Shaft Pinions.—The intermediate shaft pin-

ions are made solid and as small in diameter as is consistent with good design. These pinions wear out quite rapidly and should be so arranged as to be easily replaced.

Intermediate Shaft Gears.—The intermediate shaft gears are designed of a size to give the bucket line the desired speed. They are often made with separate rims, so that they may be replaced when worn without throwing away the rest of the gear.

Pulley-Shaft Pinion.—The pulley-shaft pinions are made similar to the intermediate shaft pinions and as small as good design will allow.

Clutch.—Whether the digging motor is belted direct to the bucket-drive pulley shaft, or to a counter-shaft on the ladder-hoist foundations and from there to the bucket-drive pulley shaft, some form of friction clutch is used to connect and disconnect the bucket drive, and for purposes of safety in case the buckets encounter obstructions beyond their strength. Any of the standard forms of friction clutches may be used, but I prefer the electro-magnet clutch and use it in all designs. It is by far the simplest to

MAGNETIC CLUTCHES FOR BUCKET DRIVE AND MAIN WINCH.

operate, is positive, and will slip at exactly the same pull every time according to the amount of current sent through its coil by the rheostat controlled from the pilot-house. The clutch used is very simple in design. A cast-iron pulley is made so that there is a flat ring or web joining the spokes at about half the distance from hub to face. To this web is bolted a soft east-iron ring. Between this and the pulley are inserted two thin sheets of copper and one of soft iron between the copper plates. These ring-shaped sheets are used in order to keep the lines of force where they are most wanted and to prevent the current making a permanent magnet of the pulley and shaft, which would cause the clutch to drag when released. The pulley has a long hub bushed with bronze and runs free on the shaft. A long cast-iron hub with two feather keyways at 180°, and a web extending out to the same diameter as the ring on the pulley is made to slide along the shaft. To this web is bolted another soft iron ring similar to the one bolted to the pulley. An annular groove of rectangular cross-section is machined in this ring midway between its inner and outer circumference into which fits a coil of magnet wire. By introducing an electric current into this coil through controller rings, magnetic lines of force are induced which will draw the two soft iron rings together, the pressure depending on the amount of current put through and the number of turns in the coil. The edges of the soft iron rings are beveled so as to make a female joint on the pulley and a male joint on the sliding hub. The steeper the slope of these edges the less current will be required to do the

*Abstract from the *Journal* of the American Society of Mechanical Engineers. Continued from *Mining and Scientific Press*, page 303.

requisite work, but if the cones are made too steep it will be difficult to disconnect the clutch; 45° does very well. Good results are given by 440 turns of No. 16 magnet wire, and 4 amperes at 110 volts are put through the coil when working average ground. These figures are for a 200-hp. clutch.

Shafts.—The shafting for the bucket drive should be made of ample dimensions and of good material. I use nickel steel, annealed, and a factor of safety of 10. The gears should be fitted very neatly and securely keyed.

Bearings.—The upper tumbler-shaft bearings are made on an angle so as to have the bearing cap at right angles to the average line of pull of the bucket line. Cast-iron liners are sometimes used, but I prefer a babitted bearing. The bearings should be well fastened so that they cannot slide forward, there being a very heavy pull in this direction. These bearings, like the others of the bucket drive, are made of cast steel. The intermediate and pulley-shaft bearings are made of the ordinary type of babitted base and cap, but are heavier than standard and use very large diameter belts, which should be made of a soft grade of iron or steel, since unless this is done they are likely to crystallize and break.

Brake.—It is customary to have the pulley shaft extended and a brake wheel keyed on. This brake is operated from the pilot-house and is used by the winchman to hold the buckets from going over the upper tumbler when the bucket line breaks, to stop quickly in case of an accident, and to hold the bucket line when making repairs or changing buckets.

Pulley.—Standard medart pulleys are generally used. They give considerable trouble on account of broken spokes. I have recently used with success a wooden bucket-drive pulley similar to that commonly employed in stamp-mills, and on the last boat I designed a medart pulley with spokes made extra heavy near the hub and tapering to a little more than standard cross-section at the rim, since nearly all the trouble arose from spokes breaking near the hub. If a cast-steel hub and spokes could be made, it would be the best pulley for the purpose. Several of the steel foundries say that they would not care to attempt to cast a spider with as small spokes as the standard medart, and that a very heavy spoke would have to be made in order to overcome shrinkage trouble. If spokes could be made of cast steel and of as light or lighter design than the standard medart, it seems as if it would be an ideal pulley for dredge use.

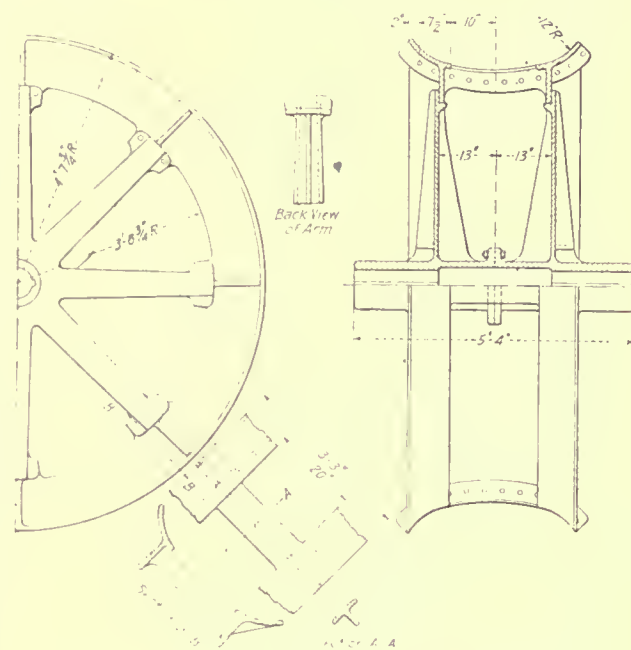

Foundations.—Too much attention cannot be given to making the supports for the bucket drive of strong construction. In the first place, these foundations are 20 to 30 ft. above the main deck and are subjected to constant and racking strains. If any portion of these supports gives, it throws the shafting out of line with obvious results. One form of support now much used and considered very good has the upper cord of the main truss made high enough to take the upper tumbler-bearing supports directly on its top. By this method the main gantry is braced fore and aft in an excellent manner, and it is a much more rigid construction than where the gantry extends above the cord. Large steel castings are used to tie the timbers together and to support the bearings directly. The details vary on different dredges and apparently have all given good service. One point which should be carefully looked into when designing this part of the dredge is so to place all bolts that they may be readily accessible and replaceable.

BUCKET IDLER. Where the depth of gravel to be dug demands a long string of buckets, an idler is used to support the sag. This idler is placed at the throat of the well as low down as convenient. It is made up of a cast-steel hub and a double set of spokes bolted onto a wide rim made to fit the curve of the bucket lip. The shaft is keyed to the hub and revolves in two bronze bushed bearings set on the deck or other convenient place.

CATCH-ALL.—Below the dump hopper an inclined set of grizzly bars is put in. These extend as far forward as the sag of the buckets will allow. The bars are put $\frac{3}{4}$

to 2 in. apart. Below this grizzly is a collecting pan which directs the gravel to the forward end of a sluice with riffles, occupying the space between the gantry posts and sloping toward the after portion of the dredge. This sluice is run back as far as the grade will permit and then dumps its contents into riffled side sluices running forward, one on each side of the well. These discharge into the well 15 or 20 ft. forward of the well throat. Water is furnished from one of the pumps and washes the material dropping through the grizzly bars.

DUMP HOPPER.—The hopper into which the buckets dump diverts the gravel into the screen. It is made either with a steel lining or by having a depression left at its bottom which fills up with rocks and gravel, thus forming its own lining. It is obvious that the last method is much more economical than the steel-lined hopper and that so far as its bottom is concerned it will last indefinitely; the only difficulty is that unless the hopper is left of ample dimensions it is likely to clog up when digging large quantities of material, particularly clay. By using a steel

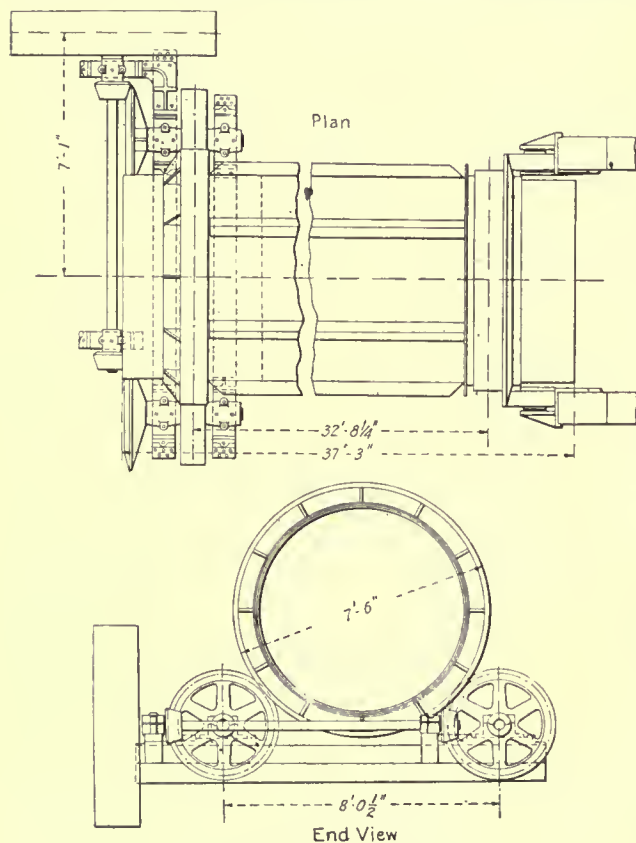

BUCKET IDLER, 9-FT. DREDGE.

lining for the bottom of the hopper a little space may be saved, and if a large quantity of clay is to be handled, the latter method might be preferable, but for ordinary conditions the rock bottom seems to be all that is necessary. The hopper is built up on three sides of the upper tumbler, the top being at about the level of the bucket lips as they go over the tumbler. The forward upward edge is built to such a height as to miss the bucket lips by a few inches when the ladder is in its lowest position, and it is of advantage to put inclined guide plates on each side of the bucket line to divert the slop-over of the buckets into the hopper below. The rear vertical wall of the hopper is subjected to considerable wear by the striking of the rocks and gravel against it when the buckets dump, and it should be lined with an easily replaceable steel plate. A good way is to suspend a $\frac{1}{2}$ -in. plate from the top by means of a few bolts, leaving the bottom entirely free.

SCREEN.—Two types of screen are in common use, the revolving and the shaking. The first dredges used the revolving screen, then the shaking type was introduced at Oroville and for a time most of the dredges were built in this way. On the Yuba it was found that these did not break up the clay in a satisfactory manner, and revolving screens were introduced. This type proved better for this district, and since then many have gone back to the revolving screen even in other districts. The object of a screen is not only to size the material passing through it, but also to disintegrate and wash it. This the revolving screen does more thoroughly than the shaking screen where clay or

cemented gravel is present. The shaking screen gives a more even distribution of the fine, requires less power to operate, and its plates last longer and are more easily replaced. For easily washed material I prefer the shaking screen, but for gravel hard to wash, the revolving type is decidedly preferable.

Revolving Screen.—The design of the revolving screen has been well worked out, and very little trouble is experienced with this part of the dredge. Most of the delays in its operation are caused by the necessary replacement of worn plates. These plates should be put in so as to be readily removable and not too close a fit made; rather leave considerable space between them, since if this is not done they will spread and be hard to take out. Bolts with counter-sunk heads on the inside and split washers under the nuts on the outside are used in preference to rivets. They hold as well and can be removed more readily. The screens are built up in sections, usually with cast-steel ribs at intervals to retard the movement of the gravel. These

REVOLVING SCREEN, 9-CU. FT. DREDGE.

steel ribs also serve as a framework, to which are fastened the perforated plates. The size of perforations depends on the conditions and varies from $\frac{3}{8}$ to $\frac{3}{4}$ in. Around each end of the screen is a steel ring or tire, preferably made in halves so as to be readily removable. Two drive rollers, on which the ring at the upper end of the screen rests, are used on most of the older dredges, but a single drive roller under the centre with two side guide rollers is coming into use on the newer boats. The rollers driving the screen are themselves driven by beveled gears and pinions. Owing to the difficulty of keeping grit out of these gears they are made of manganese steel, with a soft iron core cast in the hub. Rollers are used at the lower end to support the screen, and a pair of manganese-steel thrust-rollers are provided to keep the screen from moving toward the stern. The bevel gears are driven from a countershaft above the screen, the driving motor also being placed there. The countershaft is used in order to reduce the speed properly, so that excessively large gears or pulleys need not be used. At the lower end of the screen is a hopper, which directs the coarse gravel upon a belt-conveyor. In order to prevent clogging at this point the hopper should be placed on a grade of not less than 30° , and should be raised on the side or

which the revolving screen moves upward, the gravel being carried up on this side of the screen.

Shaking Screen.—The shaking screen is built with channel-iron sides. The bottom is formed of angle-iron cross-pieces, to which are bolted the perforated plates. The angles should extend beyond the sides, so that the top of the channels may be braced from their ends. The screens are built in pairs and mounted tandem so as to balance each other, one moving forward when the other moves aft. They are suspended from the timbers above, some using adjustable, others non-adjustable rods. The upper and lower bearings for these rods should be made of ample size, since they wear surprisingly fast, considering the small movement. The lower end of the after screen is constructed so as to direct the coarse material from the short discharge-chute upon the conveyor. This part of the screen is not perforated. The size of screen perforations depends on conditions, and, as in the revolving screen, varies from $\frac{3}{8}$ to $\frac{3}{4}$ in. The shaking screens are driven by means of four connecting-rods, operated either by cranks or eccentrics on a thwart-ship shaft. I am inclined to favor the eccentric drive, owing to its larger wearing surface. If eccentrics are used, they should have long hubs and double keyways, otherwise they are likely to work loose under the constant pounding. The drive shaft may be placed at any convenient point, but a central position between the two screens is perhaps the best. The bearings for this shaft are placed outside the screens, and as near as possible to the cranks or eccentrics, and should be long enough so that they will not beat out under the constant hammering. Buffer springs are sometimes used to take up the strain at the end of each stroke, but this practice is not common. The connecting-rods are usually made adjustable, and any of the standard methods of fastening rod ends may be employed.

Sprays.—The ordinary form of spray for washing the gravel as it passes down the screen is a perforated pipe or pipes. The water from the high-pressure pump is used, and the holes vary from $\frac{1}{4}$ to $\frac{3}{4}$ in. diameter. These holes are so placed as to direct the water where most needed. The spray pipes should have quick-opening valves at their lower ends, so that they may be flushed out when the holes become clogged with roots, grass, and other small particles of matter. Where much clay has to be washed, some of the dredges are using large-sized nozzles, set in groups at each end of the screen. It is thought that the large streams break up the clay in a more satisfactory manner than the greater number of smaller-sized streams furnished by the perforated pipes.

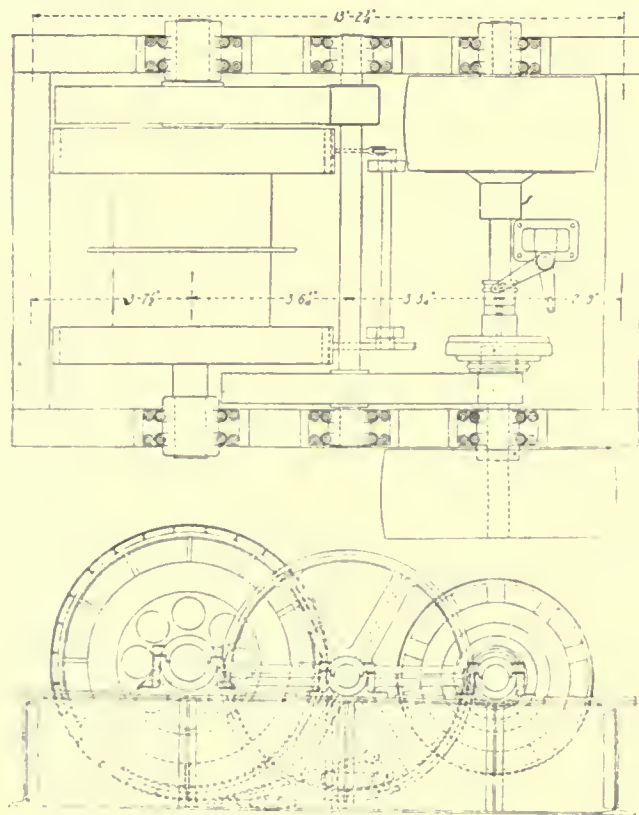

STACKER.—Ladder.—The design of a stacker-ladder is a simple matter, since the loads and conditions are fairly constant. The lattice girder is the most common type, and the strains in each member may be readily ascertained by graphic methods. I use a factor of safety of 8 for this ladder. The lower end is supported near the stern of the boat, and should be so designed as to allow the ladder to move up and down and also to allow the ladder to swing from side to side. The upper portion is supported by a bridle near the end and another near the middle. The ends of a wire rope are made fast to these bridles, its middle portion passing over a sheave which is in turn attached to the stacker-ladder hoisting-blocks. Instead of a single loop arrangement I prefer to fasten one end of the rope to the ladder-hoist block, thence passing it around a sheave at the upper bridle, then over another at the ladder-hoist block, fastening the end to the middle bridle. This puts nearly double the supporting power at the upper end and prevents the buckling upward of the ladder when the dredge is surging badly.

Conveyor Drive.—The common method of driving the belt-conveyor is by means of a motor set on supports above the ladder, 15 ft. or so back from its upper end. The motor is belted to a pulley-shaft mounted near the end of the ladder, to which is keyed a pinion with cut teeth which meshes into a cut gear on the conveyor-belt pulley-shaft. I recommend a large-size drive-pulley, covered with rubber belting. In order to make the belt contact greater, an idler is placed near this pulley, which brings the belt up and in

contact with it for a large portion of its circumference. By mounting the motor inside the ladder near the upper end a direct gear drive may be used, but this method has not been found as satisfactory as the belt drive described above. A silent chain drive is now being used a great deal. It allows the motor to be set nearer the drive, and is said to work very well.

Conveyor-Belt.—Rubber conveyor-belts are used, and should have an extra thickness of rubber on the wearing side. The most important point is to select rubber of the best quality.

DISTRIBUTOR.—Below the screen is a hopper or distributor which is used to distribute the screened material to the gold-saving tables. Here the ingenuity of the engineer may have full sway. The main object is to get the screened gravel evenly distributed on the gold-saving tables, and the way that it is accomplished makes very little difference. The distributor should be designed so that a certain amount of adjustment will be allowed to meet varying conditions.

LADDER HOIST, 9-FT. DREDGE.

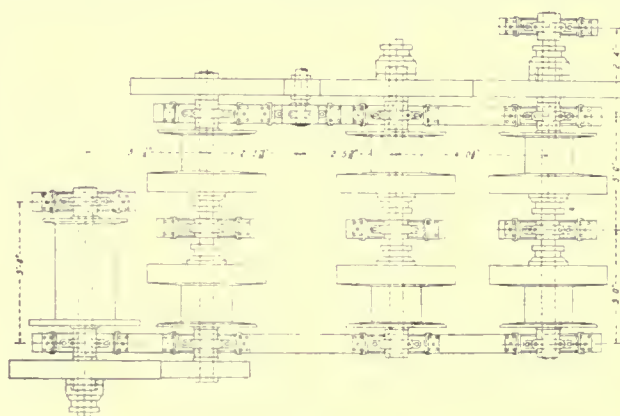

Where a shaking screen is used, the problem is simpler than for a revolving screen.

GOLD-SAVING TABLES.—This part of the dredge belongs more to the province of the mining than the mechanical engineer, so it will not be discussed at any length in this paper. Suffice it to say that the gold-saving tables should be specially designed to meet each different set of conditions. They occupy the greater portion of the dredge back of the main gantry and may be built either of plate steel or wood. I prefer steel. The tables are covered with riffles made of angle iron or strips of wood covered with strap-iron. The fine material is discharged either at the stern or some distance aft, according to conditions.

LADDER HOIST.—The ladder hoist is now usually driven by the digging motor from a counter-shaft on the main deck. In a few cases it is driven from the bucket-drive pulley-shaft on the main gantry. Owing to the load it has to carry, it is made very heavy. A structural or cast-steel base is provided, on which are mounted the bearings. Single gearing is used and ordinarily the teeth are not cut. A friction clutch is provided on the pulley-shaft to connect this part of the dredge machinery. From the standpoint of rope efficiency the drums should be made much larger than is common practice, but excessively large drums are

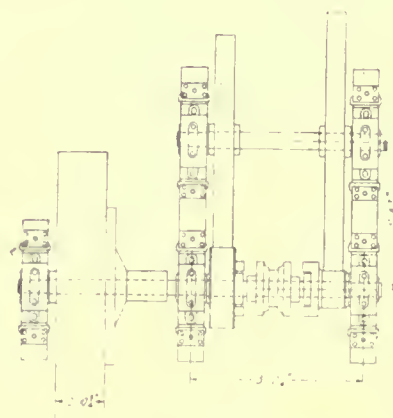

not warranted, unless the sheaves through which the same rope passes are made of corresponding dimensions. This entails increased construction cost, but I am inclined to the opinion that it would reduce operating costs sufficiently to warrant some increase in this direction beyond common practice.

The brakes on the ladder hoist must be adequate in capacity and made so that there may be no possible danger of their giving way. If the brakes on the main winch should give way, little damage is likely to occur, but if they fail on the ladder winch, a broken digging-ladder is the prob-

MAIN WINCH, 9-FT. DREDGE.

able result, if nothing worse. The following arrangement has been found very satisfactory. Two band-brakes are used, one being operated by hand from the pilot-house, the fixed end of which, instead of being fastened to the deck, is attached to a lever arm, which through a cross-shaft operates the other brake, thus giving almost unlimited power with very little effort. On most ladder hoists the drum-shaft gear is keyed to the drum shaft, and it is nearly always placed very close to the drum. It is a much better plan to design the side of the drum in such a way that

MAGNETIC CLUTCH AND DRIVE FOR MAIN WINCH.

the gear rim can be bolted to it, thus doing away with the gear spokes, making a much stronger job and taking all driving strain off the drum shaft.

MAIN WINCH.—The main winch operates the swinging lines, both bow and stern, raises the spuds, and is usually fitted with one or two head-line drums for wrecking and repair work and to step up with when one spud has been broken. The winch is driven by a variable-speed motor, which, together with the levers actuating the clutches, is operated from the pilot-house. Some form of friction-clutch is commonly used on each drum. I have for some time been using an electro-magnetic clutch on the pulley-shaft of the winch, similar to the one described for the bucket-drive, and jaw clutches for each drum. The jaw clutches are extremely simple and require no attention, whereas a friction-clutch is likely to get out of adjustment. Also, each winchman wants his clutch set differently, and unless great vigilance is exercised they will be constantly adjusting these clutches, which means lost time. The fric-

tion-clutches on each drum are easier to operate, but with a little practice the jaw clutches give perfect satisfaction. A good many dredges have a separate drum mounted on the after part of the dredge, driven from the counter-shaft of the screen drive and used to raise and lower the stack ladder. The drum is driven by a worm gear of such pitch that it will not run backward from the weight of the ladder. Other dredges have an extra drum mounted with the main winch for this purpose. It is kept from reversing by a pawl and ratchet. Considering the little use this drum gets, its position and design seem to be of very little moment, but a worm-drive and separate drum mounted aft are preferable.

Swinging-Lines.—On deep ground and for the larger dredges, the bow swinging-lines pass from the drum to a sheave, or combination of sheaves, placed near the bow, then to a sheave on the shore, and from there to the lower end of the ladder. By this method of rigging, very little side strain is put on the digging ladder or well hole. The disadvantage of this method is the necessity of a shore sheave and the consequent wear and time lost in moving and handling it. Where the ground is not too deep, a single line, which is simple to operate, but which puts a large side-bending strain on the ladder and well hole, is used. If the ladder and hull are built strong enough, this is not an objection. For the 13 and 16-ft. dredges, a single line would have to be very large and would hardly be advisable.

Brakes.—All winch drums are provided with band brakes operated from the pilot-house. The connection between brakes and clutches and pilot-house are made through bell-cranks, rods, etc. Flexible wire rope running over sheaves is used in several instances for the brakes.

Foundations.—Cast iron, cast steel, structural steel, and wood are used for foundations. I have been using wood in my recent designs on account of its producing less noise and vibration than metal foundations.

(To be Continued)

ASPHALT is being exported from Trinidad in increasing quantities. The output in 1910 was 159,000 tons, but the 1911 statistics will show increased sales. The natural supply of gold seems good for at least a thousand years. Large amounts of both local and foreign capital have been invested in exploring for oil during the past year. Modern machinery and supplies have been imported from the United States and Great Britain to be used in drilling wells and establishing necessary camps for laborers, while expert drillers have been engaged to ascertain the value of the deposits. Some wells have been opened with a large flow for a few

hours and then failed to repeat the performance. Drillers have found great difficulty, owing to the liability of the wells to get sanded and choked on reaching a depth of a few hundred feet, where apparently there is a sand stratum of unknown thickness permeated with oil. Although there are large deposits of iron ore in Trinidad and comparatively easy of reach, foreign capital has not been sufficiently interested to develop the mines, and local capital unemployed is not sufficient to warrant exploitation to any great extent.

THE NEW ZEALAND mining amendment act of 1910 provides that in addition to the duty payable on the exportation of gold under the gold duty act of 1908, there shall be payable a duty of 3d. per ounce of weight of gold of the fineness of 20 carats and upward, and in proportion for gold weighing a fractional part of an ounce, or of a lower degree of quality. Under the act of 1908 an export duty of 2s. per ounce troy of gold is levied on gold produced in the North Island only. The act of 1910 is applicable to all gold, whether produced in the North Island or the South Island.

Portland Cement Production in 1911

Complete statistics for the year 1911 were received by the United States Geological Survey during the month of January from about 70% of the portland cement manufacturers in the United States. Based on these returns, an estimate has been made by Ernest F. Burchard of the U. S. Geological Survey for the entire output for the year. It is believed that this estimate is within 2% of the exact quantity of portland cement manufactured in 1911. There was apparently a slight increase in the production of 1911 over that of 1910, amounting to about 1,300,000 bbl., approximately 77,877,236 having been made in 1911, as compared with 76,549,951 in 1910. This represents an increase of only 1.7%, as compared with the increase of 17.7 that occurred in 1910 over the previous year. The figures for 1910 and 1911 are so close that when complete returns are received possibly a slight decrease in production may be shown. The average factory price per barrel, not including packages, was 86.7c. in 1911, as compared with 89.1c. in 1910, a decrease of 2.4c. per barrel, or 2.68 per cent.

An attempt has been made to estimate the shipments of cement by districts for 1910 and 1911, but with regard to such statistics there are fewer data and the figures are not regarded as quite so accurate as those of production. The first year in which inquiries were made by the Survey with regard to stocks on hand was 1911.

Treatment of Matte From Mill Clean-Up

By M. W. VON BERNEWITZ

Matte is a by-product from the smelting of gold precipitate from cyanide plants, and the subsequent refining of the bullion by sulphur. Its formation cannot be prevented; it carries high gold content, is difficult to treat, and is generally a nuisance.

There are many methods of treating matte; among others being the roasting and smelting, acid treatment, and the cyanide reduction. On the whole, results have not been too satisfactory. I recently made an attack on an accumulation of matte at the Associated Northern Bloeks. This material was produced from the cyanide bullion by refining with sulphur. It is high in Cu, and contains Fe, Zn, and Pb. It is melted in a No. 50 crucible, and lumps of sulphur are kept under the surface by means of a small inverted clay pot held by tongs. The contents are poured into a conical mold, the matte broken off the bullion as clean as possible, and the latter finally remelted. It may be mentioned here that the matte sticks to the bullion, and has almost to be chopped off.

In reducing the matte, I used the cyanide method, as described by A. E. Drucker, in the *Mining and Scientific Press* of May 18, 1907. Briefly, this consists of crushing the ingredients to pass a 4 by 4 screen, and putting layers of borax, matte, and cyanide in a No. 60 crucible, and so on until the parcel is through. The matte and cyanide was crushed by pestle and mortar. Some 50% by weight of cyanide and borax was used, less flux and reducer give low results.

The crucible when hot, was charged with layers of each material. This did not take long to run down, and a thick seam or dross filled the pot. This was skimmed off by means of a half-round skimmer, about 6 by 2 in. at the widest part. More matte and flux was added during a three days' campaign of some 6 hours each. During the melting, a good deal of fume was given off, and it was necessary to be careful. At the end of each melt the crucible was poured into a conical mold, and a most noticeable point was that some unreduced matte did not stick to the bullion at all, this being due to the cyanide flux. I would therefore recommend the addition of a little cyanide before pouring any melt that contained matte, preferably mixing it a trifle. Following are some details of the treatment:

	Pounds.
Weight of matte.....	145
Weight of cyanide used.....	72
Weight of borax used.....	72
	144
Bullion recovered	30.5
	Au per ton,
	ounces.
The first matte assayed.....	4640
The second matte assayed.....	500
The slag, dross, or residue.....	54

This shows a high concentration and extraction. The second matte and dross was bulky and difficult to treat; it was therefore fed into the ball-mills during the next two days, and treated along with sulphide ore. The gold in this stuff must be in an extremely fine state, as it could not be detected in any samples. There was only about 40 lb. of the second matte. Sulphur did not act readily on the final bullion from the matte, so it was poured and assayed. The fineness was 540 in gold and 220 in silver, base being 240. The cost of the above treatment was as under:

	£	s.	d.	
Wages	2	0	0	= \$9.70
Fuel	1	0	0	= 4.85
Cyanide	3	2	6	= 15.15
Borax	1	11	0	= 7.49
Sundry	0	6	6	= 1.56
	8	0	0	= \$38.75

Not wishing to make more rich matte by further sulphur refining, and not liking to use nitre, we decided to try bessemerizing the bullion. A temporary pipe-line from the air-compressor to the furnace was made out of 3/8-in. pipe and 1/2-in. rubber hose. It was necessary to take the air from this point, as it was warm, averaging 91° F. at the furnace. For conducting the air into the molten bullion, we used the long clay 'Churchwarden' pipe stem, the rubber hose being bound on with asbestos twine. The stems were gently heated, and lowered into the bullion after air at 90-lb. pressure was turned on. It takes very little air indeed to keep 400 oz. of bullion well agitated. A little borax flux was used, and this picked up the base as it rose to the surface. Fairly dense zinc fume went off for some time; the air did not in any way cool the bullion; but quite the reverse, the whole mass seemed to be very hot and active. After an hour's air treatment the pipe stems got too short to be easily handled, so the bullion was skimmed with sand, and poured. The final bar was 590 fine in gold, 210 in silver, and 200 in base, showing that, with a prolonged bessemerizing of, say, 3 hours, with decent apparatus, bullion 900 or more fine could be produced. So, along with the matte treatment described, I would recommend bessemerizing low-grade bullion, as it is a cheap and easily worked method. Although not really conclusive, the bessemerizing shows that the bullion can be refined in this way, as described by Rose. Further experiments with proper apparatus will be tried.

The Tin Market

According to Vogelstein & Co., Straights shipments for the first half of February are cabled as having been 3060 tons, and for the entire month are estimated at 4700 tons. As this is not a Banca sale month, the total supplies will approximate only about 5700 tons, including 'standard' tin in the United States, but not elsewhere. Statistics will hereafter be made inclusive of 'standard' tin (99% or better), and it will be necessary to bear this in mind in making comparisons with previous months or years, just as it is necessary to bear in mind that the London Metal Exchange quotations are now for standard tin and not Straits or Australian as heretofore. The quantity of tin available for trading on the London Metal Exchange is increased by the new contract, but the quantity of tin available to consumers of the metal is not affected by the change. Granting supplies as above mentioned, and assuming usual deliveries, the visible supply will decrease by the end of February somewhere between 2000 and 3000 tons. March is a Banca sale month, but the outlook being for continued good deliveries and small supplies, statistics will probably break even in that month, just as they did in January, while in April there will be a further large shrinkage in the visible. In 1911 and 1910 stocks decreased, end of January to end of April, 4000 to 5000 tons, respectively. Should a like decrease occur this year—and there is every prospect of it—stocks at the end of April will be the lowest since 1907. Cargoes afloat will be required for consumption as fast as available, and in addition stocks must be drawn on as above indicated. The heavy syndicate sales in January consisted wholly of contracts. The stock is still entirely in their hands. Under these circumstances lower prices can scarcely be expected.

SOUTHERN RHODESIAN ORES do not, as a whole, provide such metallurgical plain sailing as do the auriferous conglomerates of the Witwatersrand. A company has recently been formed which is called the Rhodesian Refractory Minerals Process, Ltd. The company expects to have completed, at an early date, an experimental plant for the treatment of all grades of ore. A plant is now being erected by the company, adjacent to the New Found Out Mine Gadzema. This plant, besides having the necessary machinery for the Martin process for refractory ores, is equipped with a complete concentrating unit consisting of Buss coarse and fine concentrators, Lohrig vanner, and convex slime-table.

New York Meeting, American Institute of Mining Engineers

By OUR SPECIAL CORRESPONDENT

The 102nd annual and business meeting of the American Institute of Mining Engineers was begun on the evening of February 18, 1912, by the calling to order of the assemblage in the hall of the Institute, 29 West Thirty-ninth street, New York, by Benjamin B. Lawrence, chairman of the executive committee of the New York section of the Institute. After a few amusing and cordial welcoming remarks, Mr. Lawrence introduced the president of the Institute, Charles Kirchhoff. Mr. Kirchhoff reviewed the work of the Institute during the past year, and referred in his characteristic, tactful, and graceful manner to the difficulties with which the management had to contend, and its hopes and aspirations for the future in broadening the work of the organization. In this connection it is but proper to pay tribute to the unselfish devotion of Mr. Kirchhoff to the interests of the Institute during the past year. No president within my recollection ever strove harder and more unselfishly for its welfare. All honor to Mr. Kirchhoff for his devoted and ceaseless efforts in behalf of this organization. Mr. Kirchhoff ended his remarks by introducing James F. Kemp, the expected president-elect. Mr. Kemp entertained the audience by a delightful account of his amusing and fanciful experiences while on a prospecting trip in British Columbia, and followed, as an encore, with an amusing description of how ore veins are formed in Mexico and of their subsequent development by American capital. The meeting then adjourned to the ninth or office floor of the building, where an informal smoker and what the English call a 'conversazione' followed. Punch, lemonade, and cigars were served. On the whole, the evening was a delightful one, for there was a turning out of old members such as has not occurred at business meetings within the past fifteen or twenty years.

The business session of the Institute was called to order the following morning, February 20, at 10:15 o'clock, with Dr. James Douglas, vice-president of the Board of Directors, in the chair. After the reading of the minutes of the previous meeting, the regular order of business was changed. The chairman announced that, inasmuch as it was intended that a committee should be appointed to investigate the affairs of the Institute, he would call upon J. Parke Channing to introduce the motion. Mr. Channing thereupon offered the following resolution:

"Resolved that Messrs. James F. Kemp, Christopher R. Corning, George C. Stone, W. H. Nichols, Jr., and A. R. Ledoux be and are hereby appointed a committee of five to investigate all of the affairs and the operations of the Institute, to see whether an increase in dues cannot be avoided, and to report to the Board of Directors by May 1, 1912, making such suggestions as they may deem best for the welfare of the Institute, and that said Board of Directors shall cause such report to be printed and distributed at once by mail to each member, so that it may be considered and acted on at an adjournment of this meeting to be reconvened June 3, 1912.

"Resolved also, that this committee be directed and empowered to engage, at the expense of the Institute, independent clerical and auditing assistants."

As there was no opposition to the resolution, it was unanimously adopted. The matter had previously been thoroughly discussed and the program prepared by the signatories to the circular of February 3, 1912; in fact, it appeared that the investigation was welcomed by all, especially as Mr. Channing's motion provided that any action on the proposed amendments to the constitution be postponed pending the report of this committee.

The election of directors followed. F. Lynwood Garrison nominated for the three vacancies on the Board of Directors, Messrs. Edmund B. Kirby, George C. Stone, and Charles F. Rand. This nomination was seconded by F. F.

Sharpless. E. G. Spilsbury then renominated the retiring directors, Messrs. Theodore Dwight, Arthur L. Walker, and Joseph Struthers. The nominations being seconded, a contest was on. Tellers were appointed by the chair, and after the lapse of sufficient time to count the votes and proxies, the following result was announced: Kirby, 1057; Stone, 926; Rand, 926; Dwight, 340; Walker, 336; Struthers, 328. Messrs. Kirby, Stone, and Rand were therefore declared elected.

Following this election came the balloting for officers and members of Council, according to the ticket previously mailed to members. During the interim between these two elections, the chair had been taken by A. R. Ledoux. Various motions to have the secretary cast the ballot and avoid the appointment of tellers, etc., were made, but objections to this procedure were offered, and a regular election insisted upon. The tellers reported the following results: President, James F. Kemp, 1262; vice-president, Benjamin B. Thayer, 1263. Karl Eilers, 1263, Waldemar Lindgren, 1263; members of Council, Jos. W. Richards, 1263, John H. Janeway, Jr., 1263, Sidney J. Jennings, 1263; secretary, Joseph Struthers, 377.

It should be explained that the signatories of the circular issued February 3, 1912, held about 900 proxies, and voted them for all the candidates save Mr. Struthers. This was done for the reason that many, if not most, of these proxies were sent to the signatories with the understanding that they should not be voted for him. It is to be regretted that this invidious distinction had to be made, but those having possession of the proxies had no option in the matter. They either could not vote them at all for any of the candidates, or could vote them in the way they did. Not to have voted them for Mr. Kemp and his associates would have been contrary to the wishes of those giving the proxies. In view of this vote, it is impossible not to feel that Mr. Struthers is the victim of circumstances and a bad system inherited by him. The office he fills is a difficult one at any time, and especially during the critical reconstruction now at hand. The relation of the secretary to the membership has in the past been obscured, and the fact that the Institute belongs to its members, and the secretary is the servant of the organization, has never been clearly observed.

With the announcement of this vote it was evident that a new régime had come into the management of the Institute. The Board of Directors is the all-powerful body in the peculiar make-up of the Institute's management. It has been the custom for years, at the annual meeting, which was usually attended by a mere handful, to renominate and elect the retiring directors and thus perpetuate the old Board year after year. Obviously this was an objectionable practice. Now new blood comes into the Board, as well as into the Council. While at this meeting there was some suppressed feeling, it fortunately did not manifest itself in any unpleasant incidents. After the election was over, expressions of satisfaction were heard from all sides, from the defeated as well as the successful, and all seemed anxious that the Institute should prosper and continue its career of usefulness.

A luncheon followed the morning session, which was attended by many of the old members, thus affording opportunities for renewing old acquaintances and making new friends. A notable feature of all the sessions of this meeting was the absence of guests and ladies; in fact, it was a serious affair, and those people who belong to the Institute merely for 'a good time' had no interest in the gatherings. It is hoped that in the future there will be more such meetings.

The afternoon session on Tuesday was devoted to the reading and discussion of a number of interesting papers. And the discussions were not the least valuable and important part of the proceedings. Reading papers 'by title' is evidently, and it is hoped for all time, a thing of the past in the Institute. A man who takes the trouble to write a paper should be given an opportunity to read it and his friends to discuss it. This was one of the original objects of the founders of the Institute, but, like many

other of its primary functions, had fallen into desuetude. Among these papers were the following: 'The Sintering of Fine Ore,' by B. G. Klugh; 'Agglomeration of Fine Materials,' by W. S. Landis; 'The Gröndal Briquetting Process,' by N. V. Haskell; 'Sintering and Briquetting of Fine-Dust,' by Felix A. Vogel; 'The Shumacher Briquetting Process,' by Joseph W. Richards.

The banquet of the Institute was held in that gilded hostelry for the *nouveau riche* known as the Hotel Plaza, on the evening of the same day. It was 7:30 before the members—some hundred odd, with a score of ladies—sat down to the small round tables in the 'Palm Room.' The dinner was poor, but could the expensive decorations and indifferent music have been turned into food, one might have ended with a square meal. As it was, the diners got little for their five dollars each.

Mr. Kirehloff admirably presided as toastmaster; his tactfulness and graceful remarks were characteristic of the man, a delight to his friends, and were appreciated by all. Some of the other speeches were extremely tiresome. One of the appropriate after-dinner speeches of the evening was an amusing recitation by A. M. Hay, of Toronto. He made everybody laugh, which was refreshing, and a relief to the dull monotony of this dreary affair. The meeting of Wednesday, February 21, was devoted to the discussion of papers; in other words, was a technical session.

On the whole, it is probable the future historian of the Institute will record that the business meeting held in New York on February 20, 1912, was one of the most, if not the most important event, in the history of the organization since its foundation. For truly the very existence of the Institute as a technical or semi-technical organization trembled in the balance. Those in charge of its management could not or would not see wherein and how it could be improved and developed from an invertebrate to an organization having character and vitality, as well as backbone and stability. Had this been realized years ago, there would have been no need for a Mining Congress, a Mining & Metallurgical Society, and the number of smaller mining and allied organizations which have sprung up throughout the country within recent years. The Institute could have done all this work; the men who have vitalized and made the little Mining & Metallurgical Society a thing of importance and of weight as a national organization would have been only too glad to lend their brains and strength to the work of the Institute, developing its character, broadening its scope of work, and making it a national organization in fact as well as in name. The American Institute of Mining Engineers should claim and have the interest and sympathy of every earnest and honest man connected with the mining industry. There is no need or call to change its name, for with all its faults, which were chiefly those of omission, it has done nothing to dishonor that which it has proudly borne for forty-one years. The essential thing to remember is that its strength will be governed by the character of membership, and above all, that it, as an organization, belongs to all its members and not to any few who happen to be elected its officers.

AN extensive deposit of naturally concentrated monazite sand has been discovered near Quilon, Travancore, India. This sand contains 4% of thorium, and consists of from 46 to 50% of monazite, with ilmenite and zircon as the other chief constituents, together with some rutile and traces of spinel, garnet, quartz, and hornblende. A specimen of pure monazite separated from the sand contained 8.5% thorium. The monazite can be concentrated by an electro-magnet. A specially prepared concentrate contained 8.87% thorium, and pure monazite separated from this contained 10.08% thorium. The commercial concentrate contains 5 to 6% thorium, as compared with less than 4% in the Brazilian sand, and the pure monazite from the Travancore deposit is richer than that from the Brazilian and Carolina deposits, resembling the monazite from Ceylon. Monazite is chiefly used as a source of the rare metal oxides which are so extensively used at present in the manufacture of mantles for incandescent burners.

Goldfield Consolidated Report

During the month of January the total production of the Goldfield Consolidated Mines Co., according to the report of J. F. Thorn, general superintendent, was 28,870 tons, containing \$733,344, or an average of \$25.40 per ton, the whole being milled with an average extraction of \$24.14 per ton, or 95.02%. The total net realization was \$471,140, or \$16.32 per ton.

During the month 3302 ft. of development work was performed. The total cost of mining, development, milling, office and general expense was \$7.92 per ton, distributed as follows:

Mining:	
Development	\$1.00
Stoping	3.14
	— \$4.14
Transportation	0.07
Milling	1.98
Marketing	0.50
General expenses	0.50
Bullion tax	0.21
Construction	0.52
	—
Total cost of operation.....	\$7.92
Miscellaneous earnings	0.10
	—
Net cost per ton.....	\$7.82

The 413-sill of the Clermont was again extended, and produced 722 tons of ore averaging \$24.18. The new 428-sill, now being cut from the 466-ft. intermediate between the 600 and 750-ft. levels, produced 500 tons of ore averaging \$41.34. The 604-H raise from the 1000-ft. level, going up toward the 534 on the south end of the 900-ft. level, produced 381 tons of ore averaging \$72.06.

The 3-E sill in the Mohawk, on the 150-ft. level, near the old Sheets-Ish workings, was again extended, and produced 503 tons of ore averaging \$56.43. The sill in the 111-K was extended and produced 571 tons of ore averaging \$57.46. The 111-M sill produced 218 tons of ore averaging \$18.19. The 415-X cross-cut from the 491-ft. intermediate, between the 450 and 600-ft. levels, produced 174 tons of ore averaging \$38.44. The 305-DX stope in the Red Top was extended above the second level, and the resulting sill produced 70 tons of ore averaging \$22.73. The 403-CX stope on the fourth level, at the 442-ft. cross-cut, produced 70 tons of ore averaging \$22.53. The 403 sill was extended and produced 18 tons of \$28.52 ore. The third level has been connected with the Laguna shaft, and station and pocket completed at this point, and during the present month the Red Top surface plant will be dismantled. In the Combination, the 295-X on the fourth level, south and west of the Hampton stope, produced 45 tons of ore averaging \$41.34. The roasting plant has been completed, and both furnaces are now in successful operation. The results from the new plant have fully justified all expectations.

Mexican Mineral Production

According to the statistics of the Department of Finance, Mexico produced in the fiscal year 1910-11 gold to the value of P\$49,615,289.25, and silver to the value of P\$80,913,799.32. This was an increase of over P\$1,000,000 in gold, and more than P\$4,000,000 in silver, compared with the preceding fiscal year. The statistics are based on exportation, gold and silver coin being eliminated. Any gold and silver bullion that was being held in the republic probably was exported during the year under review, due to disturbed conditions. The production of copper is placed at P\$26,300,228; lead, P\$6,539,098, and zinc, P\$899,925. Compared with the fiscal year 1909-10, there was a slight increase in the production of copper, and decrease in the production of lead and zinc. This is a good record, considering the disturbed political conditions.

The Reno Co-operative Potash Laboratory

There has been established at the Mackay School of Mines, Reno, Nevada, a laboratory for the examination of natural material suspected of containing potash. It is under a co-operative agreement between the Mackay School of Mines, the Bureau of Soils of the United States Department of Agriculture, and the United States Geological Survey. It is in charge of George J. Young, of the Mackay School of Mines, with A. R. Merz, of the Bureau of Soils, as chemist. Facilities have been provided for the examination and assay of potash-bearing materials, and of saline waters and minerals. It will be possible, also, to examine a limited number of samples for contained nitrates. Samples of suspected potash or nitrate bearing materials will be examined free of charge for prospectors and others, so far as limitations of time and equipment of the laboratory will permit, but all samples must be accompanied by: (1) the name and post-office address of the owner, locator, or discoverer of the deposit; (2) the exact place from which the sample was obtained; (3) a description of the material and its surroundings, and of the manner of taking the sample.

This information, or any part of it, will be kept confidential if so requested. However, it should be noted that the laboratory does not agree to make complete analyses or to make quantitative assays, except as rendered desirable by the result of qualitative tests.

Potash occurs in nature in two classes of compounds, those soluble in water and those insoluble. Insoluble compounds, such as alunite, leucite, certain feldspars, and various other minerals, may prove of value as a source of potash, but as yet no process has been developed for the successful commercial extraction of potash from these materials, excepting possibly in the case of alunite, which is used in Italy as a source of potash alum. The co-operative laboratory does not agree to examine such insoluble materials. The soluble potash compounds, which are the only ones of present commercial value, include potassium nitrate or nitre, potassium sulphate, potassium chloride, and various double salts of potassium with other elements, notably kainite, a compound of potassium chloride and magnesium sulphate; and 'manure salts,' a variable mixture of chlorides and sulphates of potassium, sodium, magnesium, etc., containing from 15 to 40% of potash. The supply of all these materials is now obtained from Germany, excepting potassium nitrate, which comes mainly from India, and the present prices on the Atlantic seaboard are approximately as follows, all being expressed in dollars per ton of 2000 lb.: potassium nitrate or nitre, about \$65; potassium sulphate, about \$45; potassium chloride, about \$35; kainite, about \$8; manure salts, about \$13.

The value of any natural material containing soluble potash salts will depend upon the percentage of potash and upon the other materials, especially the other soluble salts which are present and from which the potash must be separated. Materials which do not contain too large proportions of these other salts, and in which the potash occurs as salts other than nitrate, will be worth from 50c. to \$1 per unit of potash per ton. Similar materials containing potassium nitrate will be worth 75 to 100% more. The decision as to whether any particular material can be profitably worked will depend upon so many special and local conditions that no general statement can be made.

Among the possible places of occurrence of soluble potash salts within the United States are the inclosed basins of the Western deserts. Ordinary surface waters usually carry small quantities of potash, and, since these basins have no outlet to the sea, any potash salts which have been carried into them by streams must still be there. It is conceivable that in some of these basins workable deposits of soluble potash salts may have accumulated either on the present surface or in the beds which underlie it. The latter possibility is being tested in one of the basins by the well now being drilled by the United States Geological Survey near Fallon, Nevada, as described by H. S. Gale in Bulletin

530-A of the Geological Survey. In addition to this, the surface conditions in other basins are being examined by agents of the Bureau of Soils and the Geological Survey, and the indications for or against the occurrence of potash are being studied. A preliminary report of the fertilizer resources of the United States containing a discussion of available surveys of potash salts will be found in Document No. 190, United States Senate, Sixty-Second Congress, second session. If potash occurs on the surface of any of these undrained basins it is doubtless associated with the saline materials of various kinds usually found on and underneath the central sink or *playa*. Its presence therein will probably be detectable by examination of the salts of this *playa* or of saline springs in and about it. Such springs may also furnish information as to possible potash deposits in the deeply buried beds.

The identification of potash in the field is by no means easy, since the other salts with which it is associated usually mask its peculiarities. The best general field test is conducted as follows: A fragment of the suspected material is moistened with potash-free water, placed on a platinum wire or strip, and inserted in the flame of an alcohol lamp or other lamp the flame of which is colorless, the flame being at the same time observed through a piece of blue glass of a special kind, known as cobalt glass. If any considerable quantity of potash is present it will give to the flame thus viewed a peculiar violet color, which is quite characteristic and easily recognized after once being seen. The platinum wire, alcohol lamp, and cobalt glass employed in this test can be secured from any dealer in chemical supplies. By the use of the spectroscope the delicacy and accuracy of this test can be somewhat increased, but the spectroscope is both expensive and difficult to operate, and it cannot be recommended to persons inexperienced in its use. Potash salts of high purity can be recognized by taste, but those occurring in nature are usually so impure that the taste ceases to be characteristic. Interested prospectors are advised to procure the materials for the flame test and become proficient in its use, and to retain for chemical analysis any samples which give the potash color.

The Rise in Silver

The recent quotation of 59 $\frac{3}{4}$ c. per ounce for silver represents approximately 5c. rise since the first of the year. This advance means much to the silver-producing properties, as each 1c. per ounce over and above the cost of production represents additional income. Thompson, Towle & Co. gives the following list of the largest silver producers in the United States, Canada, and Mexico, with their annual production in ounces, and the increased yearly income which these companies should make, due to this 5c. rise in the metal.

Property.	Annual Prod. (Ounces.)	Increased Income Annually.
Anaconda	10,000,000	\$500,000
United States S. & R. Co..	10,000,000	500,000
American S. & R. Co.....	7,000,000	350,000
Nipissing	5,500,000	275,000
Tonopah Mining	4,700,000	235,000
Tonopah Belmont	4,000,000	200,000
La Rose	3,700,000	185,000
Wetlanfer	925,000	46,000

A PAIR of 300-hp. gas-engines to be served by a wood-burning producer have been built in England for shipment to Brazil, where the plant is to be installed in a cotton-mill extension. Two single-cylinder, double-acting, two-eye engines drive on a countershaft so arranged that the stoppage of one engine need not interfere with the working of the other set. About 300 hp. is taken from the countershaft by the shafting of the mill extension and the other 300 hp. by an electric alternator which supplies current for the motor-driven machinery of the dye house. The wood-burning plant is adapted for ready conversion to coal consumption.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Making Mine Ladders

The Editor:

Sir—Some time since it was necessary to equip our 2000-ft. shaft at Nueva Luz with ladders, and for a shaft of this depth it was important to design a ladder of long life, easily constructed, lending itself to prompt repair, and with all risky elements eliminated.

The spacing of the plats being 15-ft. centres, it was decided to make all ladders of a uniform length of 18 ft., constructed of clear lumber of 2 by 4-in. sides, each ladder having 17 rungs, which involved the purchase or manufacture of 2200 rungs.

A native wood known as *pala dulce* (a species of hick-

MAKING LADDER RUNGS.

ory) is renowned for its strength and longevity, especially in wet places, and the employment of this was decided upon, but the question of having these turned true, straight, and uniform, without a lathe, next arose. However, having a circular saw, and 'necessity being the mother of invention,' by the ingenuity and resourcefulness of our master mechanic and superintendent, J. M. Lovret, a simple attachment was evolved for the saw bench, with which it has been possible to shape rungs of excellent form, true

holes. One man can easily turn out ten finished ladders, including dipping in carbolineum, to which treatment all timber is subjected before being sent into the mine, in a day of ten hours. The illustration shows a rung just finished, by a native boy who prepares 320 rungs easily in a ten-hour day. The details of the attachment are shown in the drawings, and while the apparatus may be worthy of patent, I prefer to offer it for what it is worth to other brothers in the profession who may want to get themselves and men out of a hole, in more ways than one.

Is 'Cheap' Labor Economical?

The Editor:

Sir—I have read with interest your recent articles on China and Chinese labor, and the following table, based on my experience out here in various places, may interest your readers somewhat. The rate of pay is in gold dollars (or cents) per day, and the efficiency is figured on the basis of an American miner taken as 100 per cent.

	Efficiency, %	Rate of pay.
Russians	100	75c. to \$1
Koreans	90	20 to 30c.
Northern Chinese	70	10 to 20c.
Southern Chinese	60	10 to 20c.
Japanese	60	40 to 80c.
Javanese	40	12 to 30c.
Filipinos	40	50 to 75c.

These figures are based on trained men in their own countries under average conditions.

In the Federated Malay States the southern Chinese working for whites get from 25 to 40c. (gold) per day, and in Sumatra the southern Chinese get the same as the Javanese. Much depends on the personality of the white foreman, in any case; and the advantage of the white laborer is that he uses his head, while, with the exception of the Korean, the others do not, except in some cases when they are contracting. This applies to underground work. There are good men among all of them, and if you have the time and patience, a good crew can be beaten out of most any material, but it is certainly wearing on the nerves of the white man, and not many of them can do it successfully. A good, sober, husky bunch of Russians can do as much as any other kind if they are well handled, but the same lot with indifferent handling can do as little as possible just as well. It all comes down to the personal equation and the methods employed. The Filipino is the worst I have yet found, but if you take enough trouble and have enough material to work with, a fairly good crew can be had. But for the prevailing wages they are the most expensive of any Asiatic labor I have seen.

Survey Reports and 'Boosters'

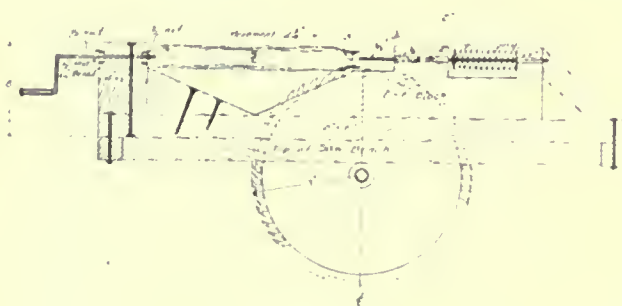

The Editor:

Sir—The conclusions expressed in certain reports of the U. S. Geological Survey dealing with mining districts in Colorado have been so often misquoted or misconstrued in the daily press as to call for some general protest, which may best be made by reference to two recent examples.

In a review of mining published in a Denver paper of recent date, in reference to Lindgren's work at Cripple Creek (Professional Paper No. 54, U. S. Geol. Surv.) it is stated that:

"While the people of Cripple Creek, or some of them, questioned the accuracy of his report on that district, where-in it was in substance intimated that the endurance of rich shoots to points far below 1200 to 1500 ft. was quite doubtful, no hard feeling resulted."

The foregoing words, with some other phrases not quoted, give the impression that the Federal geologists (Messrs.

DETAILS OF SAW ATTACHMENT.

to a centre line at each end, with a slightly increasing shoulder which gives the desired rigidity when the bolts are tightened. The pipe spreaders are useful in preventing the application of too great a pressure, which might cause splitting of the sides.

The sides are bored, two at a time, in an ordinary horizontal boring machine, equipped with a 1 1/4-in. wood bit, driven by the same motor that runs the saw. It takes an average of four minutes to bore the seventeen pairs of

Waldemar Lindgren and F. L. Ransome, who, it should be noted, were joint authors of the report and equally responsible for its conclusions, although only Mr. Lindgren is mentioned in the article) discouraged development below 1200 to 1500 ft., and that their opinion has since been proved erroneous. The following paragraphs from the Cripple Creek report (pages 231-232), if read with care at all commensurate with the attention bestowed by the authors on their phrasing, will, we believe, show that the implications put upon them in the article cited are unwarranted.

"As has been pointed out in the preceding pages, the largest known orebodies of the district are apparently confined within a zone which extends from the surface to a depth of 1000 ft. In general, explorations below that depth have been much less satisfactory as regards quantity of ore than exploration above. It is certainly true that some large orebodies as yet show no signs of depletion in depth, and that some good pay-shoots have been found at a depth of 1400 to 1500 ft. On the other hand, the number of ore-shoots that have been exhausted with increase in depth is considerable.

"It is probable that the orebodies, known or unknown, occurring below the 1000-ft. zone are neither so large nor so abundant as those nearer the surface. The discovery and exploitation of these deeper orebodies is, moreover, beset with increasing difficulties, chief among which is the problem of dealing with the underground water. For these reasons it is unlikely that the zone between the 1000-ft. and 2000-ft. levels will yield as much as the zone between the surface and the 1000-ft. level, but it is probable that some strong fissures may carry payable ore to far greater depths than those yet attained.

"As regards the zone above the 1000 or 1500-ft. levels, it is well to bear in mind that it still contains much ore, both as parts of known ore-shoots and as yet undiscovered orebodies. It is certain that many of these undeveloped orebodies will be mined in the near future and that this zone will contribute the most important part of the production.

"It is probable that the production of the district, while exhibiting fluctuations, will, on the whole, slowly decline. New orebodies will undoubtedly be discovered from time to time, and individual mines may be as profitable in the future as they have been in the past, or even more so. An increased output may be expected to follow each successful step in deep drainage. But existing conditions indicate that if the maximum production of \$18,000,000, in 1900, is to be surpassed, the increase will be due to the orebodies found in the upper zone."

We maintain that our well-considered statements made in 1906 are correct and are in accord with such facts as have been brought to light by subsequent mining developments.

Similarly, in another Denver paper with reference to the Breckenridge report (Professional Paper No. 75), Ransome is credited with the statement (given as a quotation) that "probably nowhere in the Breckenridge district does profitable lead ore extend below a zone 300 ft. below the surface", and reference also is made to "the Ransome barrier, beyond which barrenness was predicted." Neither the sentence quoted nor the prediction referred to is to be found in the report. The actual expressions in that publication that appear to have suggested them to the press correspondent are as follows: In the outline prefixed to the report appears the statement that "Lead ores of shipping grade probably nowhere in the district extend to a depth of much more than 300 feet." In the body of the report it is said of the Lucky, Minnie, Ella, and Cincinnati mines that "all had some galena or cerussite ore of shipping grade near the surface, but at various depths, not accurately ascertainable, though probably nowhere exceeding 300 ft., this ore gave place to more pyritic material." On the following page appears this paragraph:

"Doubtless if complete records were obtainable of all the idle or abandoned mines, they would largely be a repetition of the same story—partly oxidized lead ores near the surface and sphaleritic or pyritic ores below. Even the imperfect data now available establish without much

question the limitation of the lead ores to a zone ranging from 200 to 300 ft. deep and corresponding roughly to the present strongly accidented topography. There may, of course, be exceptions to this apparent rule; the underground workings are not extensive enough to afford a basis for sweeping assertion. The statement made, moreover, is far from implying that there is no galena below a depth of 300 ft.; but all available evidence indicates that in this district 300 ft., or perhaps more safely 400 ft., is the limiting depth for the occurrence of considerable bodies of essentially galena ore as opposed to sphaleritic or pyritic ores."

This article also credits Ransome with an alleged erroneous statement regarding a fault in the Dunkin vein, whereas there is no reference whatever to this fault in the report.

There appears to be a perhaps unconscious tendency on the part of writers for the daily press to seize upon any generalization in an official report that may be at all unfavorable to a mining district, to exaggerate this and to disregard those careful qualifying statements that are an essential part of the conclusions reached by the geologist. The plain duty of the latter is to base his results squarely and honestly on the evidence obtainable at the time when he does his work, and to state these clearly and impartially. It is equally incumbent upon those who criticize these results to verify impressions and hearsay by direct reference to the original publication and to quote with fairness and fidelity.

F. L. RANSOME,
W. LINDGREN.

Washington, D. C., February 13.

Mineral Production of California

By W. H. STORMS

The State Mining Bureau is rapidly compiling the statistics of mineral production of the state for 1911, and the following figures on some of the minerals produced have been prepared by E. S. Boalich, statistician for the Bureau.

Advance report of mineral production in California in 1911. Amount and value of crude product at the mine, as reported by the producer. Subject to a possible increase in the final bulletin for 1911.

Barytes—	Tons.	Value.
1911.....	309	\$2,207
1910.....	860	5,640

This represents the output from Mariposa and San Bernardino counties. Never produced in the state previous to 1910. The outlook is for an increased and regular production, as the general use of ground barytes in the manufacture of mixed paints, white enamels, and asbestos cement is gradually increasing.

Feldspar—	Tons.	Value.
1911.....	740	\$4,560
1910.....	760	5,720

Output from Monterey and Tulare counties. This is also a new industry, the first product being sold in 1909. Most of the feldspar is used for the manufacture of pottery.

Graphite.—The total graphite production of California amounts to only 106 tons, marketed in 1901 and 1902. Deposits of the mineral are known, and the owners of a graphite mine in Sonoma county are preparing to resume work in 1912.

Infusorial earth—	Tons.	Value.
1911.....	2,194	\$19,670
1910.....	1,843	17,617

This is from Monterey and Santa Barbara counties and is about an average annual production. The demand for infusorial earth is not strong, or other properties would be worked.

Iron—	Tons.	Value.
1911.....	558	\$558
1910.....	579	900

Special Correspondence

TORONTO, CANADA

DECLINE IN PORCUPINE SHARES.—POWER IN PEARL LAKE DISTRICT.—MINES MAKE GOOD PROGRESS.—SETTLEMENT OF NORTH DOME CONTROVERSY.—SALE OF GREEN-MEEHAN.

For some time there has been a continuous depreciation in Poreupine stocks, with occasional short-lived rallies, but on the whole a steady downward tendency and little market activity. The frequent postponement of the date of actual milling operations by the trading companies, and the giving up of options on properties taken over conditionally, but which proved disappointing, have considerably weakened the faith of the public in Poreupine ventures. No doubt the experience of Cobalt, where many of the earlier enterprises gave quick returns, has tendered to make many investors unduly impatient for results and unwilling to make allowance for the necessarily slower and more elaborate and costly processes involved in gold mining.

The mines in the Pearl Lake district have at last secured a supply of electric power from the Sandy Falls on the Mattagami, the installation having been a good deal delayed by the nondelivery of equipment when expected. Connections with the system have now been made by the Vipond, the McIntyre, and the McEneaney (the last operated by the Crown Reserve company), and the Hollinger and Pearl Lake will very shortly be using the power, so that development work in this area will receive a great impetus. The Dome has its stamp batteries and tanks erected, and it is now expected that the mill will be in operation by the middle of March. Good progress is being made in blocking out ore on the 50-ft. level. At the Dome Extension a rich stringer cut at 90 ft. in No. 4 shaft has been found to widen considerably a few feet lower down. Another has been found in an adit on the 100-ft. level from No. 8 shaft.

The purchase of a controlling interest in the North Dome by the directors of the Temiskaming aroused a strong feeling of opposition among the shareholders of the latter company. The American shareholders appointed Ernest C. Whitbeck and Wallace Thayer to represent them and investigate the deal. They have just presented their report exonerating the directors from all blame and pronouncing favorably on the transaction as resulting in obtaining a splendid property at a low price, and likely to perpetuate the dividend-paying power of the company. The annual report of the Crown Reserve is of an optimistic character, showing a production for 1911 of the value of \$1,833,516 and net profits of \$1,279,739, of which \$1,061,288 was paid in dividends. The total surplus on hand was \$764,851, and the estimated value of ore on the dump, \$500,000. The shareholders of the Green-Meehan, at a meeting held on February 12, authorized the sale of the property for \$150,000, in payments spread over a term of six years. The purchasers are a syndicate of American capitalists, who propose to resume development and to erect a mill in the near future. There is reported to be \$75,000 worth of ore on the dump. Kerr Lake has declared a dividend of 5% for the first quarter of the year. The payment of an extra bonus has been abandoned. The production of the Trethewey for 1911 amounted to 716,464 oz. of silver, valued at \$273,486, a figure slightly below that of the previous year, owing to the amount of time devoted to development.

At Larder Lake the Dr. Reddick is doing steady work. The 20-stamp mill is in operation, though not to full capacity all the time, the ore supply not yet being sufficient. A new drill has been added to increase the output, and as soon as the orebody is sufficiently blocked out, a Hardinge mill will be added, which will double the capacity of the stamps. The Harris-Maxwell is erecting a 40-stamp mill, having already 30 stamps in place. Electric power is being developed in the neighborhood, which it is anticipated will be available early in the spring.

GLOBE, ARIZONA

SIX UNITS IN OPERATION AT MIAMI.—DRILLING ON OTHER PROPERTIES.—NEW SUMMIT COMPANY.—NOTES OF DISTRICT.

The Miami Copper Co. is producing at the rate of 2500 to 2600 tons of ore per day, with five of the six units of the concentrator in operation. The three 8-ft. Hardinge pebble-mills for the sixth and last unit have arrived, and the sixth unit is now running also. The type of skip known as the Original Con. Mines Co. skip has been discarded in favor of the old Kimberly type of skip, which is reported to be giving better satisfaction with much less repair cost. Exploration of the company's ground northeast of the present developed orebody continues, by means of churn-drilling. Hole No. 2 of the Southwestern Miami Development Co. is down 780 ft. and is now in iron-stained silicified schist. Two more churn-drills are to be added in the near future. F. W. Hoar, of Globe, is manager. The churn-drill hole in the 300-ft. shaft on the Barney group, under option to the Lewisohns, is 1030 ft. deep and still in the dacite formation. A large flow of water was met at 965 ft. and water is now flowing out of the top of the hole.

At the Live Oak mine, enlargement of No. 2 shaft to three compartments is progressing rapidly under the man-

GLOBE, ARIZONA.

agement of the contractor, Jack Melvor. The boilers are being bricked in and the double-drum hoist is being erected. A small amount of development work is being done from No. 1 shaft. One churn-drill is in operation on the property of the New Keystone company near the shaft. The hole is being drilled through the granite formation that caps the ore in this vicinity. E. B. Tinker is superintendent. There is nothing new on the Inspiration Consolidated. Construction work will not be started until a jury in the district court has awarded a compensation to the property-owners along the proposed right-of-way from the town of Miami to the Inspiration and Live Oak mines. This will not occur for at least thirty days. In the meantime, construction of the dam across Pinal creek, sinking of the well on the Inspiration ranch, and operation of the experimental mill continue. A statement has been issued by the directors to the shareholders of the Summit Copper Co., which recently surrendered its lease and option on the Gibson mine, 16 miles west of Globe. The report shows that \$164,000 was derived from the sale of stock and \$28,000 from the sale of ore; \$141,000 was expended at the mine in its development, and \$46,000 was paid on the property. The report states that in the opinion of the directors a sufficient tonnage had not been developed to warrant further expenditure on the property. The directors have secured an interest in a gold prospect in the Radersburg district, Montana, and offer to holders of Summit Copper Co. stock two shares in the Summit Gold Mining Co. for every five shares in the Summit Copper Company.

The Gibson mine is being worked in a small way by the Gibson Copper Co., to whom the mine reverted. Ten men are at work under the supervision of Tip Henderson, one of the original owners of the mine, and a small amount

of high-grade chalcopyrite ore is being taken out on the fourth level. Ore is now being hauled to Miami, preparatory to making a carload shipment to the El Paso smelter. Another carload of silver-lead ore was shipped from the Copper & Silver Zone group last week. Four parties of lessees are at work on this group two miles east of Globe, and all are now working in ore. The ore is coming from near the surface, there being as yet no deep workings on these claims. The silver occurs as the chloride or horn-silver, and the lead as the carbonate and galena.

JOPLIN, MISSOURI

HYDRAULIC MINING TRIED SUCCESSFULLY IN OPEN-PIT PROPERTY.—STRENGTH OF SPELTER MARKET ENCOURAGES OPERATORS.—OLD LAND IS REOPENED.—ZINC AND LEAD NOTES.

By utilizing high pressure from a centrifugal pump, prospectors in the open pit of the old Wyssbrod mine, at Zincite, west of Joplin, are able to do successful hydraulic mining at a depth of 100 ft. The new company is known as the Two Mikes; this is the first time hydraulic mining has been done in the Joplin district. The prospectors at first shot down the dirt from the sides of the pit, but found this expensive. When it was decided to try hydraulicking, a pipe was run from the pump and a T placed in such a manner that the water is forced at high pressure into a large pipe which may be easily moved. The method is of great assistance in finding the richer ore deposits. Chunks of almost pure zincblende and galena, larger than a man's body, have been washed down. The necessary volume of water is obtained from the pit; the used water flows into a sump, from which it is pumped to the surface and discarded. The ore is milled in a 100-ton plant.

Despite the tariff agitation, which may result in the removal of the protection on zinc, the metal is unusually strong, closing February at \$6.65 to \$6.75, only 7 points beneath the record price of last December, which was the highest metal figure in years. East St. Louis quotations are given. As a result of high spelter, producers of zincblende are getting a reasonably strong price for their output, as high as \$48 per ton, assay basis of 60% metallic zinc, having been paid for many lots. This brought the top price for choice blende to \$51 per ton. Weekly shipments were badly curtailed through February because of heavy snows and freezing weather, which combined to cut down the output from the mines as well as to curtail the removal of much of the concentrate in the bins. The heaviest week's shipment, 6000 tons including calamine, was made about the middle of the month, prior to and after which time the shipments almost invariably fell to 5000 tons or below. Lead, on the other hand, weakened, metal dropping from \$4.40 per 100 lb. to \$3.925, then recovering to \$4 toward the close of the month. Ore as a result dropped in price from \$64 per ton to as low as \$48 per ton, then recovered and went to \$52.

The old I-Know land, in the west part of Joplin, which has not figured in the production columns for years, is coming into notice through numerous good discoveries, both in virgin ground and in old workings, made during the past few weeks. It would seem that there is some truth in the local saying that a Joplin mine can never be worked out. Although this old tract was mined extensively—once being the foremost producer of the district—it has lain dormant for years until recent operations have revealed big deposits of ore. The Old Dominion Mining Co., of which C. M. Sheldon, of New York, is president, has first lease on the land and has sub-leased it to several small prospecting and operating companies. Half a dozen of these sub-leasing companies are at work, and the old mill on the tract has been overhauled and remodeled to be used as a custom plant for those mines producing mill-dirt. Many of the mines, however, are operating in soft ground and the dirt is cleaned on hand-jigs.

Mining land in the new Lawton, Kansas, district, is no longer confined to the 320 acres opened by the Eastern

Lead & Zinc Co., the pioneer concern of that field. On adjoining properties many churn-drill rigs are hammering away, and in half a dozen instances north and northeast of the Eastern property, good drill strikes have been made, at depths ranging from 120 to 150 ft. West of the tract, ore has also been found on one lease. Both zinc and lead are found, but the water is troublesome. Up to this time the single company has been forced to handle all the water, but with new concerns starting, the drainage problem should be greatly simplified. Among the new companies at Lawton are Walter Ragland, C. H. Stoats, and R. L. Milton (two drill-holes into 9% dirt); Gates & Gray (five drill-holes into dirt of varying richness); Walter Koontz & Co. (no finds reported yet); George Playter (12-ft. face of zinc and lead in several drill-holes).

LONDON

OIL FLOTATION PROCESSES.—ELMORE ANNUAL REPORT.—MINERALS SEPARATION STATEMENT.—RESULTS WITH THE MUREX MAGNETIC PROCESS.—THE CORDOBA COPPER MINE.

The various flotation and oil processes of concentration have been prominently before the public in London, owing to the chairmen of the controlling companies having addressed their shareholders at considerable length. The first meeting held was that of the Ore Concentration company, which controls the Elmore patents. The progress reported was not great. The Sulitjelma plant, treating copper tailing in Norway, has been increased from 12 to 18 units; two new plants have been started recently in Canada; and a mine in Mexico has enlarged its plant to three units. The company has not yet arrived at the stage where a profit and loss account can be rendered.

The meeting of the Minerals Separation company was held shortly after, and John Ballot, the chairman, made a long statement containing a great deal of interesting matter. He was able to present a profit and loss account for the first time, and showed an income from royalties and profits from treatment of £82,600. He recommended that all administration and experimental expenses should be written off, and full allowance made for depreciation of plant, so that the company should be able to go forward in the future free from incumbrance and in a first-class financial position. He estimated that the net divisible profit from present contracts would be £30,000 per year, which on a capital of £50,000 is sufficiently good. The company is continuing to treat tailing and old residues at the Sulphide Corporation's Central mine at Broken Hill, and is able to treat low-grade zinc tailing and also slime at a profit. The company prides itself on having been successful in making a better profit on the material owned by the Zinc Corporation than the Elmore plant could do. Over a year ago the Minerals Separation plant was substituted for the Elmore plant, and the controversy between the rivals has been acute ever since. Mr. Ballot's process has given more efficient results, according to the comparative figures given by him. Taking the returns over the period of treatment during the five months, March 1 to July 31, 1911, when the two processes were running side by side, he showed that 66,450 tons of zinc tailing and slime was treated by the Minerals Separation process, producing 27,525 tons of concentrate, and yielding a profit of £35,109, or 10s. 6d. per ton. The Elmore plant treated 61,550 tons, giving 18,897 tons of concentrate and yielding a profit of £13,300, or 4s. 3d. per ton. Mr. Ballot announced that a Minerals Separation plant is to be adopted at a South American copper mine owned in the United States, the name of which I am not allowed to disclose. It has already been announced that James M. Hyde has started a Minerals Separation plant at Butte, on his own account and in defiance of the company's patent rights. The lawsuit for infringement will be heard before long. Mr. Hyde was engaged by the company as engineer, two years or so ago, and while in their employ he learned the details of operation. From the standpoint of professional honor he ought to use his

information only for the benefit of the company, but relying on the fact that oil, bubbles, and flotation were not entirely unknown thirty years ago, he considered that the United States courts would afford him protection against the alien inventor and litigator.

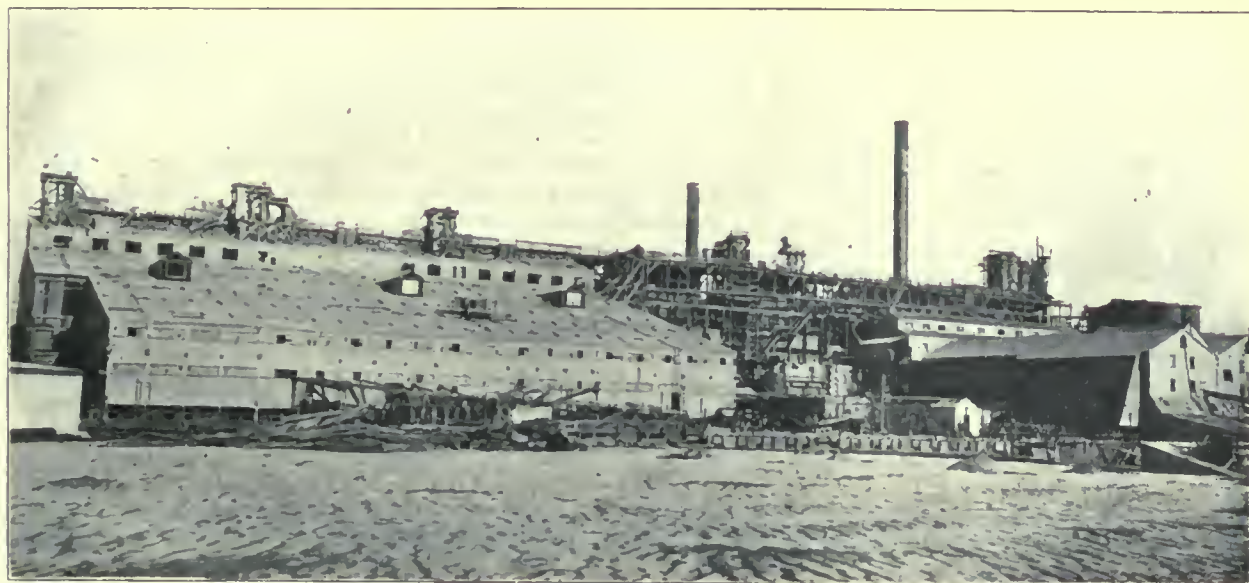

The third company holding its meeting was the Murex Magnetic, which was formed by people connected with the Shell oil interests (whence its name), in April 1909, for the purpose of acquiring a concentration process invented by A. A. Lockwood. The process consists of adding magnetite or other magnetic substance to the ore together with some liquid that will make the particles of magnetite and the sulphide or other mineral in the ore agglomerate and form granules that are susceptible to magnetic influence. It is claimed that the process is effective under many circumstances when the flotation processes fail. Full details were given in the issue of *The Mining Magazine* for October 1909. When the process was first started, arrangements were made to test it at Broken Hill Block 14 mine, where it was supposed that it would be welcome, as the sulphide ore is not being mined. But the mine did not

iron; and another contract in Mexico is pending. The Whim Well copper mine in northern West Australia is being supplied with a plant that is to treat carbonate ore; if the process is as successful at the mine as it was on the bulk sample, the beneficiation of carbonate ores in this way will mark a notable epoch in concentration.

NEW YORK

DULL DAYS IN WALL STREET.—THE COPPER SITUATION.—PRODUCTION IN 1912.—ACTIVITY AT GIROUX.—MIAMI DEVELOPMENT.—ALASKA COPPER MINES.—NIPISSING DIVIDENDS.—THE SAN TOY.

Most of the ordinary topics of discussion in Wall Street have been laid aside for the time being, and wherever men congregate the talk is of the evil days upon which the Street has fallen. It is well within the truth to say that there never was a time when business conditions and political conditions were so generally and universally the chief topic of conversation, and equally true that there has never been

CONCENTRATING MILL OF THE BROKEN HILL PROPRIETARY.

afford proper facilities for demonstration, so the plant has been removed to the Amalgamated Zinc (De Bavay's), where it will be worked and watched by interests that will acquire the Australian patent rights if the results are favorable. Another step in connection with Broken Hill is the financing of the South Extended mine. The reason for this policy is that otherwise there was no opportunity for applying the process in this district, owing to the metallurgical problem having been solved in other ways to the satisfaction of the various boards at all the other mines. The company, with the help of friends, has undertaken to subscribe for a maximum of £55,000 debentures in South Extended, to be paid in installments according to the success of the development: £30,000 is to be spent for that purpose and £25,000 later on plant. The results of development work thus far obtained are reported as satisfactory, and large bodies of ore assaying 24½% zinc, 11½% lead, and 2.8 oz. silver have been proved. As regards the application of the process in other parts of the world, good results are reported from the Cordoba copper mine in Spain. The plant at Malines in France, where zinc-lead sulphide in a barite gangue is to be concentrated, has been delayed, owing to lack of power, but is now running satisfactorily. During the past year several important new contracts have been obtained. One is with the Prussian State in connection with a mine in the Harz mountains, where a finely disseminated lead ore, intimately mixed with silica and barite, is to be treated. A plant is being erected at the Mazapil mine in Mexico to treat a complex ore containing lead, zinc, silver, and

a time when there existed so many divergent opinions, both as to cause and effect. The one thing which is certain is, that Eastern financial centres are facing an increasingly serious situation. It is quite out of the question for Wall Street as an institution to long maintain itself on the present volume of business, and the Street is beginning to recognize the fact that the present depression is not a mere slowing down between waves of speculation, but is in reality a change in the method of investment business by the public at large. It is merely a coincidence that the public has turned away from speculation in Wall Street at a time when the spirit of unrest is worldwide, but the natural business depression in Eastern financial centres is thereby intensified. So far as the drift of affairs concerns mining, it may be confidently said that when the public attempts to once more go into mining enterprises on an adequate scale, the methods of mining promotion will be much improved, many of the just causes of complaint heretofore existing will be removed, and the shareholder who has very often been treated as of no importance beyond the mere furnishing of money, will hereafter be considered a partner in the enterprise. When this result shall have been achieved, some of the real progress now being made will become apparent. It is not to be expected that the coming year will see any important mining enterprises launched. For the time being it is utterly impossible to secure any public support for the development of mines. The uncertain situation in Mexico closes that field until an adequate police power shall have been established by the Mexican Government, whether that of Madero or his successor.

The copper situation is paradoxical. In explanation of the failure of the share market to respond to improved conditions in the metal market, it is now said in some quarters that J. R. Finlay's position is a correct one, and that the prices which have ruled heretofore in copper have been almost uniformly too high. If it is true that the public is accepting and acting upon the principle that all dividends paid by mining properties are in part liquidation of assets, this is, in and of itself, a long step forward. The copper situation was the subject of a very wide, well planned, strong manipulative movement, beginning before the close of last year. There is no way of absolutely determining the fact, but there is a widespread public impression that refinery figures were manipulated by operating pools, to show the largest possible decrease in surplus, the object being threefold: to obtain better prices for the metal; to frighten the domestic consumer into laying in supplies; and, if possible, to work up something of a boom in copper shares. This manipulation was based on, or at least assisted by, the buying of the European Governments for armament and arsenal requirements. Apparently, the price movement did not reach the hoped for levels. The domestic consumers, while interested, very largely stood pat. The share market did not secure enough public support to result in any movement worth chronicling. There was one tangible result achieved, however, and that was a marked stimulus to production. The Amalgamated Copper Co. is to turn out 30,000,000 lb. per year in excess of last year's production. Utah Copper is expected to increase its output by more than 20,000,000 lb. The Alaska properties are unknown quantities, but recent shipments from the Bonanza mine aggregate some 2,500,000 lb., and inasmuch as this is by way of initial output, the rate may be expected to increase rather than otherwise. It is safe to predict a record-breaking production for 1912. The all important question is, whether consumption will continue to absorb the metal in such quantities as to prevent demoralization. There is one strong factor now to be considered which has not previously existed; the controlling interests in the production of copper constitute a much smaller circle than at any preceding time, and a rigid policy of curtailment can be instituted and much more readily enforced in the future than at any time in the past. If this were not true, the threatened over-production of copper would be a real menace instead of a possibility.

The distribution of the cash and the Anaconda shares in the treasury of the Butte Coalition will begin March 12. In addition to the Anaconda stock, shareholders will receive a fraction more than \$4.41 per share. The transfer books close March 1. Boston is taking more interest in the development of new properties than any other financial centre of the East. Two years ago Lake and Indiana were the sensations of the Boston market. At the present time Old Colony and Mayflower are absorbing the attention of speculators and investors. In both properties the drill has shown some surprising cores, and in each case it is expected that an important producer will be developed. H. H. Rogers has been with the majority for some years. It hardly seems appropriate that F. Augustus Heinze should have issued a court summons for important figures in the copper world without including the name of the late Standard Oil Amalgamated master. The United Copper Securities Co., which was organized just after the 1907 panic for the avowed purpose of rehabilitating the various copper properties controlled by Heinze, has recently begun a suit against the Amalgamated Copper Co., the Anaconda, the Butte Coalition, which is just going out of existence, the Lewisohns, and the executors of the estate of the late H. H. Rogers, John D. Ryan and James Stillman. To those who are familiar with the days when Heinze so hopelessly enmeshed the courts of Montana in litigation, the present suit will seem like a page out of history. Upon what charges the present action is based does not as yet appear.

Expected production from the Giroux is the cause for considerable activity for both the Giroux company, which is making every effort to get the Morris shaft into shape, to turn out 900 tons of ore per day, and the Steptoe plant at Ely, which is making preparation to handle the addi-

tional tonnage to be shipped under the recent contract. The water problem at Ely is a serious one. The smelter has not as much water as it needs, while in the Giroux getting rid of the water has been a problem. At the Steptoe plant they are installing additional settling-tanks and re-pumping apparatus.

The Alunee, in the Lake Superior district, was one of the particular bones of contention in the bitter fight over the Calumet & Hecla consolidation. The property is making good the claims which were made for it. The final figures for the year 1911 have not been given out, but it is expected that they will show something less than a 7c. copper cost for 1911, and this, with all construction charges debited against this account. The average recovery during 1911 was 25½ lb. of copper per ton of ore treated.

The development of the Miami Copper Co. has been somewhat overshadowed by its larger neighbor, the Ray Consolidated. However, Miami is now expected to be the first of the developing properties to enter the dividend class. It is announced semi-officially that the first disbursement will be made during the coming spring. Miami is now earning dividends at the rate of \$1,800,000 per year, which is equivalent to \$2.40 per share upon its outstanding stock. The January output of the Miami figured something under 8½c. per pound. During the coming year, copper costs are expected to be reduced to between 7c. and 8c. The Bonanza Copper Co., which is a close corporation, the stock being practically all divided between J. P. Morgan & Co., Kuhn, Loeb & Co., and the Guggenheim interests, has just paid its initial dividend. Shipments were begun in April last with the Copper River railroad completed as far as the Bonanza mines, and the ore that was sent out aggregated something more than 16,000 tons averaging close to 70% copper. It is not within the range of possibility that shipments of this nature will continue indefinitely. A concentrating plant has been nearly completed, and low-grade ores will be shipped in the near future. It is reported that Cappel, Radycliffe & Co., of London, have purchased a copper mine in Glacier Creek, 42 miles east of the Bonanza mine, owned by the Guggenheims, in Alaska, for a sum in excess of \$1,000,000.

The annual report of the Nipissing is in process of compilation, and will be completed about April 1. Figures covering the ore reserves will show an increase of 1,300,000 oz. above the estimated reserves of December 1910. The total ore reserve as of December 1911 is estimated at 7,800,000 oz. The dumps are estimated to contain an additional \$1,000,000 worth of ore. The cost-sheet will not vary materially from that of the preceding year, when Nipissing made its silver for 14.71c. per ounce. Prospecting in 1911 was nearly at a standstill, the company doing not more than one-fourth of its usual amount of exploration work; nevertheless, the property produced bullion to the amount of approximately \$2,500,000, and, so far as ore reserves are concerned, stands with its position unchanged. The maker of old proverbs who first propounded the theory that "there is greater pleasure in anticipation than there is in possession" must have had mining enterprises in mind. From a mining standpoint, Nipissing has been a continual triumph. Its production today shows an enormous profit. It sold up to \$30 and better before it was a regular producer, and at the present time it has not any regular market following at less than one-fourth of its record high price.

The amount of stock to be issued by the International Smelting & Refining Co. for new construction will be \$2,000,000, or 20% of present capitalization of \$10,000,000. It may be late this year or early next year before allotment is made, as the company is in no immediate need of money. One of the objects of the increase will be the enlargement of the Raritan refinery. Since its organization three years ago, the International has constructed a copper refinery at a cost of \$2,000,000 or \$3,000,000, and a lead plant. In addition, the capacity of the Raritan refinery has been greatly enlarged. The company will also build a lead refinery. All this construction work has been done without increasing capital stock from the original \$10,000,000. Net earnings this year are expected to reach 15 per cent.

General Mining News

ALASKA

JUNEAU

The Alaska Treadwell has declared dividend No. 96, of 75c. per share, payable February 28.

The December returns for the Alaska United G. M. Co. show that the Ready Bullion mill (120 stamps) ran 29 days, 10 hr., during the month, and crushed 18,200 tons of ore, containing \$22,193 in free gold, and saved 474 tons of concentrate containing \$18,967. Of this, \$40,756 was recovered at an operating profit of \$11,484, or \$2.20 per ton milled. Construction expenses amounted to \$330. The 700-Ft. Claim mill (120 stamps) ran 29 days, 17 hr., and crushed 19,593 tons, with a total gold content of \$50,121. Operating expenses were \$45,501, leaving a profit of \$4119. This corresponds to a yield of \$2.55 per ton, as the operating expense includes \$15,000 paid in settlement of the Mexican powder explosion. Dividend No. 65, of 20c. per share, payable February 28, has been declared.

The report of the operations of the Alaska Mexican for December shows that the 120-stamp mill ran 29 days, 17 hr., and crushed 18,858 tons of ore of a gross content of \$59,403. Of concentrate, 484 tons, of a content of \$32,456, was saved. The operating profit for the month was \$34,648; the yield per ton milled was \$3.15. Construction expenses amounted to \$3792; development work done during the month was 209 ft.; the stock of broken ore was increased 9661 tons. Dividend No. 65, of 20c., payable on February 28, has been declared.

ARIZONA

GILA COUNTY

P. S. Tate and the Lyle brothers, who are leasing on the 100-ft. level of the Black Warrior mine, are shipping a carload of copper-silicate ore to the smelter at El Paso.

The concreting of the Kingston shaft of the United Globe is progressing satisfactorily under the supervision of Paul Michaelson, contractor, and C. H. Weideman, construction engineer. The first section of 160 ft. has been completed, and the work has been going at the rate of about 12 ft. per day. Work on the second section will begin at once. C. B. Eades is concrete inspector for the United Globe company.

From the Duquesne group, 15 miles west of Globe, there has just been shipped another carload of gold-lead ore. The last shipment of 39 tons, a few weeks ago, netted about \$18 per ton, and this shipment is expected to run even better. The ore is peculiar in that it contains gold and lead, but no silver. John F. Shaw is manager for the company.

It is reported that the Miami Copper Co. has taken an option upon all the unsold ground in lower Miami, but the report is unconfirmed.

MOHAVE COUNTY

Twelve men are at work on the tramway from the Rainbow mine, and it is hoped that it will be transporting ore by the end of this month. It is planned to ship a carload daily to the smelter. The new hoist is in place at the Badger, and the main shaft is being sunk. The adit will also be driven farther in the vein. A good body of ore has already been blocked out.

SANTA CRUZ COUNTY

The Providencia G. M. Co. has been incorporated with O. P. Posey as president; E. Titcomb, vice-president; E. K. Cumming, treasurer, and A. G. Fraser, secretary. Nogales is the headquarters. The Float Gold Amalgamated M. Co. mill is ready to start, and a new hoist has been installed at the mine. Lew Hartman is manager. It is reported that a large body of high-grade ore has been found in the Three R mines, near Patagonia.

YAVAPAI COUNTY

The unwatering of the main shaft of the Arizona Bonanza mine, near McCabe, is progressing well, and when the

water is all out, sinking to the 200-ft. level will be started. J. H. Farrell is general manager.

YUMA COUNTY

J. M. O'Brien, O. W. Picotte, Joseph Nelson, and H. Osburn have bought the Roberts mine for \$25,000, bond and lease, one-fifth payable in six months and the remainder in one year. Twenty men will be employed, and a road will be built and a tramway constructed from the main adit. This mine is the old Aviata property, in the Riverside mountains. J. M. O'Brien will be in charge.

CALIFORNIA

AMADOR COUNTY

In the Fremont mine, in the Drytown district, good ore has been found on the 1950-ft. level and promises to persist. A. Goodall is manager of the property and Wales Palmer is superintendent. At the Pacific mine in Plymouth, supplies are being received daily and additions are being made to the working force of 20 men.

BUTTE COUNTY

Much excitement has been caused at Oroville by the find made by Charles Willet on the Ida McCallum place, about 200 ft. from the county road, at Berry Creek. Willet has been working on the claim for two years and has made a living from what gold he has been able to pan. He asserts

BALAKLALA SMELTER, CORAM.

that very high returns per pan can be gotten from the vein, which is reported to be 2½ ft. wide.

CALAVERAS COUNTY

(Special Correspondence).—The Ingomar Con. G. M. Co., which has just been examined by Alexander Hamilton of San Francisco, is about to resume operations. The mine is in the Campo Seco mining district, near the Penn Chemical Co., and shows a large low-grade orebody which has been developed to the 300-ft. level and is still in the gold-bearing zone. With deeper development a copper deposit in many respects similar to that of the Penn is expected to be found. Mr. Hamilton will be manager for the company.

Campo Seco, February 20.

A local company has been formed at Mokelumne Hill to uncover old sluice-boxes, believed to have been covered by a landslide on the east side of Stockton hill, in 1857. The unusually heavy rains of the winter of that year caused a slide which buried the sluices to a depth of 30 to 40 ft., just before the clean-up. V. M. Weil and George Gilmour are visiting the mine of the Standard Amalgamated Exploration Corporation, at San Domingo. Miners from the Hanby mine are endeavoring to secure payment of their wages.

ELDORADO COUNTY

A. Baring Gould has bought the interest of Phoebe Wilson in the Fortuna, Logan, Brighton, Belle, and Jackson lode claims for \$1250. Hughes & Benny, having a lease on the old Landecker mine, have cleaned up \$225 from 35 cars of ore.

INYO COUNTY

Jack Curtin, L. W. Munzinger, and A. H. Swallow have discovered a strong vein of zinc ore in Wayland canyon, southeast of Bishop. M. C. Hall and Dick Kennedy have a lease upon L. W. Munzinger's claim north of Hamil and expect to ship a good many sacks of ore in the near future.

F. M. Myrick has made a contract with the Southwest Turquoise Co. for the total output of his bloodstone deposits. The report of the Skidoo Mines Co. for the month of January shows that 1615 tons of ore was milled and \$18,316 in bullion produced at a net profit of \$6377. Development cost was \$824 and operating cost \$814.

Al. D. Myers has bought the old Panamint mine, near the foot of Telescope peak. This is an old silver producer which is reported to have yielded \$2,000,000 to \$3,000,000, but was closed down in 1893. Mr. Myers has had the property under bond for the past nine months.

MARIPOSA COUNTY

It is reported that the Honeycomb mine, near Hornitos, is rapidly being put in shape to resume production. Mr. Brace is superintendent. J. W. Barcroft, one of the owners of the No. 1 mine, states that the mine will soon be in operation.

MONO COUNTY

Both the Standard and Hydro-Electric power plants at Bodie are suffering from shortage of water, and the Standard has laid off 27 men for this reason. N. R. Taylor, weather forecaster, says that the Sierra Nevada and Siskiyou mountains are almost bare of snow, while in normal years there is 10 to 12 ft. of packed snow on their summits.

The Golden Gate mine, in Antelope valley, has been bonded to a Philadelphia syndicate for \$250,000, according to Nevada reports. The engineer's report on the property shows \$200,000 worth of ore blocked out. The main vein is 5 ft. wide and averages \$14 per ton, free milling. Six miners are now employed, and two 50-ton Lane mills have been ordered.

NEVADA COUNTY

(Special Correspondence.)—Two shifts are advancing the adit 500 ft. at the Native Son mine, near Blue Tent. The adit is expected to tap the vein at an approximate vertical depth of 80 ft. San Francisco people are principally interested. J. H. Bishop is manager. The adit at the Mark Alling group of claims, near Columbia Hill, is in 370 ft. and will be continued to the 600-ft. point, where a raise will be made hoping to cut the Grizzly Ridge channel. This deposit was worked years ago and yielded rich profits. Pasadena people are interested. A. B. Call is manager. Developments at the Champion group are progressing well and the recently installed pumps in the Champion and Providence shafts are handling the water without difficulty. It is understood the unwatering of the Champion shaft to the bottom level will soon be under way and that vigorous development will follow.

Nevada City, February 24.

J. A. Graves and H. O. Kohler have purchased the interest of Jacob Kohler in a group of mining claims on Poorman's creek. There are several veins on the claims, and all have good surface showings. The new owners will prospect the property.

PLACER COUNTY

The Auburn Chamber of Commerce has passed resolutions endorsing H. R. No. 17033, introduced by John E. Raker, establishing a mining experiment station at Auburn. Samples of magnesite and asbestos have been sent to the State Mining Bureau in San Francisco for exhibition. H. Godds and Luther Eubanks were asphyxiated in the adit of the California & Hawaiian Development Co. at Ralston Divide. The adit is being driven to cut a buried gravel channel, and the men, who were going on shift, were overcome at a point 2000 ft. from the portal. The last round had been fired 2½ hours previously.

SIESTA COUNTY

It is said that the big stack at the Balaklala smelter, 250 ft. high and 24 ft. in diameter at the base, is gradually falling to pieces, a large portion of the top having come away, leaving large cracks extending downward for 10 ft. The structure cost \$30,000. Perry Skillman, who is in charge of the mine, says that the prospects for the resumption of work are encouraging. The plant of the Noble Electric Steel Co. is at present closed for repairs.

SISKIYOU COUNTY

Twenty-nine power companies operating in this county and in southern Oregon have been joined in a \$10,000,000 merger under the name of California-Oregon Power Co. The head office will be in San Francisco. C. L. Proebstal presented a paper at the Mining Congress at Medford, dealing with the mines of Siskiyou county, which have produced \$6,911,425 in gold from 1901 to 1911.

TRINITY COUNTY

The La Grange hydraulic mine is running only two giants, as the water-supply is unusually short for this time of year. Even these two have to be shut down at intervals to let the reservoir fill. There is but little snow in the mountains, and there is therefore little chance that the supply will increase much. J. H. Bennet, a laborer, who had been employed at this mine, committed suicide recently by drowning in one of the lakes above La Grange.

TUOLUMNE COUNTY

An electric pump of 600 gal. per min. capacity has been installed in the Springfield mine. At the Shawmut operations were resumed February 19, and 40 stamps are at work on good ore. Drilling is in progress on the Dondero gravel claim, near Yankee Hill, to determine its value. The hoist at the Confidence mine has been moved to the Cherokee, near Columbus, and exploration to determine the value of the latter will be carried on.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—A. Swanson has secured a lease on a block of ground at the Bellevue-Hudson mine on Columbia mountain. The shaft will be sunk 100 ft. from the 14th level. Ore is showing in the bottom that mills 700 oz. silver and 3.50 oz. gold per ton. Work has been put under way in the driving of an adit on Leavenworth mountain to intersect the Key West vein at a depth of 250 ft. E. J. Butts is manager. The Prudential adit on Republican mountain has cut another vein. Scattered ore is showing, but driving will not be started until the hanging wall is reached. F. A. Maxwell is manager. Heavy shipments are going out from the Linn mill. The concentrate consists of lead, zinc, and iron. Bishop & Gay, of Empire, have taken a lease on the Pittsburg mine on Silver mountain. Work is being carried on through the first level, and stoping is under way on an 8-in. streak of \$24 ore. Shipments will start soon. The Denver adit is being driven steadily forward, having been advanced 1300 ft. A vein will be cut within 50 ft. F. Brady is manager.

Georgetown, February 24.

Smelting charges on zinc ore have been raised \$1.50 per ton by the Western Chemical Co. As the railroads have been allowed by the Interstate Commerce Commission to increase their freight rates from Colorado to Kansas and Oklahoma points by 50c. per ton, some of the zinc mines and mills have closed down. Water rights in all the ditches of District No. 7 have been adjudicated by P. L. Palmer, as referee. The decision affects water rights in seven counties.

LAKE COUNTY (LEADVILLE)

Stewart & Murray are negotiating for the purchase of the Gordon-Tiger mine in the Twin Lakes district. The property has been in litigation for some years, but the title was recently quieted. The price mentioned is \$300,000. The plans for the Helena mill have been approved, and the machinery will be contracted for soon. At the American Zinc Co.'s mill it is planned to put in a small conveyor to facilitate loading cars from the iron dump. The 54-hp. compressor and 37-hp. hoist for the St. Louis adit are in course of erection. Both are electric-driven, and will be used to sink a winze 450 ft. for prospecting. The tramway cable for the Mt. Champion was recently taken to the adit by unwinding it from the reels and making five small reels. The rest of the machinery will be conveyed on a specially constructed sled. The ore-bins and trestle at

the Chip are completed. Leadville operators are concerned over the recent ruling of the Interstate Commerce Commission raising the freight rate on zinc ores to Kansas and Oklahoma 50c. per ton. The recent rise in the price of silver has stimulated interest in the low-grade oxidized orebodies on Fryer and Carbonate hills, and it is possible that if silver remains at its present price, many old properties will resume operation.

OURAY COUNTY

The Camp Bird mine has apparently taken a new lease of life and 100 more men are reported to be put at work, following a good find of ore in winze No. 527, sunk from the fourth level of shaft No. 2, 1200 ft. below the outcrop and 1700 ft. east of the shaft. The ore is 3 to 4 ft. wide and averages \$40 per ton.

SAN JUAN COUNTY

The Silverton section of the American Mining Congress, at a meeting held February 8, drafted a protest against the adoption of the Underwood act reducing the tariff on zinc, lead, and tungsten, and has sent copies to W. H. Taft, Murry Guggenheim, John A. Martin, and Messrs. Rueker and Taylor.

SAN MIGUEL COUNTY

The Smuggler-Union M. Co. is putting into operation in its mill the system of milling devised by the Portland G. M. Co. for its mill at Victor. When the alterations are completed it is expected that the gold recovery will be raised to 90% and the silver to 85 or 90%. The saving now being made is 85% of the gold and 65% of the silver. It is expected that the production of the Smuggler will be almost doubled by the alterations.

TELLER COUNTY

The Jerry Johnson shaft, on Ironclad hill, is being sunk by 3 shifts at the rate of 3½ ft. per day. Fred Johnson is breaking ore 30 ft. wide in the Pride of Cripple Creek. Lessees on the Maud Helena are shipping 2-oz. ore. Oscar Fogleman has taken a 3-year lease on the Old Gold mine, on Beacon hill. J. M. Roach, of Chicago, is backing him. In the Elkton, development is in progress on the 10th level; the main vein is three inches wider on this level than on the 9th. The water-level is receding 5 in. per day, and the shaft is now being sunk farther. The Six Points is producing 8 to 10 cars per month of 5 to 10-oz. ore. Three drills are at work, and a cross-cut is being driven on the 525-ft. level.

IDAHO

C. A. Stewart, professor of geology and mineralogy at the University of Idaho, presented a discussion of the need for a geological survey of Idaho at the Northwest Mining Congress at Spokane, and resolutions of endorsement were passed.

BLAINE COUNTY

Patent has been issued to the Hope Gold M. & M. Co., Ltd., for the Hope, Eclipse, and Eclipse No. 1 Extension lode claims. A. Richardson has located the Violet and the Agnes lode claims, about ¾ mile northeast of the Tiptop claim.

TWIN FALLS COUNTY

The Calidaho Extraction Co. is planning to erect a 10-ton plant at Twin Falls to treat black sand to recover its gold by an electro-chemical extraction process.

MONTANA

BROADWATER COUNTY

There is considerable excitement among those who have properties in the Radersburg district, in consequence of the finding of some unusually good ore in the Barnato, a property in which F. Augustus Heinze became largely interested last summer. The mine adjoins the Keating. The Barnato was located several years ago, but after some work had been done it was abandoned. Mr. Heinze had it examined last year, and on the strength of the report made to him, he secured the property after a personal investigation.

SILVERBOW COUNTY

New auxiliary hoists for the Diamond, West Colusa, Mountain View, Tramway, Pennsylvania, Badger State, Mountain Con., Neversweat, and St. Lawrence mines have been ordered from the Nordberg Mfg. Co. The adit of the Laurium-Montana M. Co., 3 miles south of Butte, has cut the vein at 285 ft. Oscar Karri is manager. The new surface plant of the Tuolumne is now in operation. Three-deck cages are being used, but when skip-pockets are cut on the 1200, 1400, 1600, and 1800-ft. levels automatic skips will be employed. Development on the lower levels is disclosing good ore, and it is expected to make arrangements with the Washoe smelter to ship 500 tons per day.

The Butte-Alex Scott is shipping 150 tons of ore per day to the East Butte smelter and expects to increase this soon to 200 tons. Air is being substituted for steam on the main hoist and is expected to make a considerable saving in operating expenses. The Butte-Ballaklava has applied for a transfer of its suit against the Anaconda from the district court to the United States district court, alleging that it cannot get a fair hearing before a Butte jury. Ore claimed to assay over 14% copper has been found on the 2800-ft. level of the High Ore.

NEVADA

LANDER COUNTY

(Special Correspondence.)—Utah and Nevada people are organizing the Austin Central Mining Co., with 1,000,000 shares of a par value of 10c., to operate the Austin Central. This property is in the Austin district, and the ore assays well in silver and carries some gold. The veins are said to be 10 to 22 in. wide. The King Midas Mining Co., operating in the Clear Creek district, has purchased a Beers roller mill, 40-hp. gasoline engine, air-compressor, and other machinery. They are expected to arrive soon and will be immediately erected. It is officially stated that ore valued at \$100,000 has been developed. Willard E. Hales is manager.

Austin, February 23.

LYON COUNTY

Road building to the McConnell mine has been completed, and shipments to the Wabuska smelter have begun. The Mason Valley mine is shipping 300 tons per day to the smelter, using an 8-ton Jeffrey electric locomotive to haul the cars from the stopes to the belt-conveyor which fills the tramway loading-bins. The tramway is a 2-cable Leschen and cost \$75,000 to construct.

NYE COUNTY

(Special Correspondence.)—The adit of the Mineral Hill Con. company is in about 490 ft. and is progressing rapidly. It will soon be under the Burr-Thomas workings, where a winze is being sunk on a rich shoot 10 in. wide. The Steffner lease on the Manhattan Con. reports finding a vein ranging 20 to 35 ft. wide, said to assay from \$20 to \$25 per ton, to a depth of 200 ft. The station on the 200-ft. level of the new shaft has been completed. The Associated Mining & Milling Co. has contracted to purchase 2000 tons of \$20 ore from this lease, deliveries to be made during April and May. It is stated that a first payment of \$5000 has been made. The Associated people are also said to have contracted for the output of the White Caps lease. A recent estimate placed the ore reserve developed in this lease at 5000 tons, ranging from \$10 to \$20, with a 3-ft. shoot declared to average \$100 per ton. John Kirchen, manager of the Tonopah Extension company, and associates recently acquired control of the White Caps lease. The Lennon mill is treating 46 tons of ore per day, stated to run about \$20 per ton, from the Big Four lease. Treatment costs average \$3. It is said that 92% is recovered by amalgamation. The mill includes 120 stamps, tube-mill, Dorr classifier, an Oliver filter, and precipitation press. It is under lease to the Big Four Leasing Co. On the 300-ft. level of this lease the vein has been stoped for a distance of 110 ft. and shows a width of 46 ft. in places.

Manhattan, February 23.

WHITE PINE COUNTY

Work at the Giroux is concentrated upon getting the Morris-Bunker Hill property in shape to ship by May 1. The Giroux shaft is now completely repaired, but sinking will not be resumed for the present.

In the Zack shaft of the Ely Consolidated Copper Co. a 3½-ft. vein containing 17.7% copper and \$1 in gold and silver has been cut. The company now has ore of workable grade in the 400, 500, and 600-ft. levels, and plans are being made to sink the shaft 200 ft. farther.

The Lead King M. & M. Co., with claims near McGill, has found 80% lead ore. A. P. Spitke is manager. The Ely Gibraltar, north of McGill, is finding galena in its 860-ft. adit.

NEW MEXICO

GRANT COUNTY

The Chloride Flat M. Co. expects to ship another carload of silver ore to the smelter at El Paso. It is rumored that the Phelps-Dodge interests may reopen the Leopold and Tyrone mines.

MCKINLEY COUNTY

H. H. Holbert and John Schauer are opening coal mines in this county, and it is reported that Santa Fé engineers are surveying a branch line through Aztec canyon to the properties.

SOCORRO COUNTY

(Special Correspondence).—February promises to be the record-output month for the Ernestine Mining Co. The clean-up for the first 10 days of the month produced 10,365 oz. of gold and silver bullion and 6 tons of concentrate. The third week's ore treatment was 675 tons. The new oil-engines are reported as a complete success. The Socorro Mines mill is again in full operation, on power from new De La Vergne oil-engines, which were started this week. Approximately 200 tons of ore is now treated daily. At the Deadwood Mines 6½ ft. of good ore has been cut on the 500-ft. level; other developments are equally satisfactory, a total of 40 ft. being driven the past week. The mill treated 225 tons. The semi-monthly clean-up is now in progress. A new find has been made in the Treasure Mining & Reduction Co. mine, specimen samples assaying as high as \$5000 in gold and silver. The mill is treating over 75 tons daily. The lessees on the Deep Down have found 18 in. of ore assaying \$48 per ton. The work is being pushed and arrangements made to begin regular delivery of ore to the Deadwood mill as soon as possible. The new Olds 12-hp. gasoline hoist, set up at the South shaft on the Pacific mine of The Oaks Co., was started last week and is proving entirely satisfactory. Sinking is in progress and a winze has been started in the adit at a point where good ore was discovered. All the ore produced in development is being treated in the Deadwood mill.

Mogollon, February 23.

OREGON

DOUGLAS COUNTY

The Beaver Hill, near Anchor, owned by J. C. Olinghouse and N. G. Chandler, has 100 tons of ore on the dump and shows assays as high as \$60 per ton. The adit cuts the vein at a depth of 400 ft., and another adit has been started.

JACKSON COUNTY

Mrs. Cora Morgan will construct a custom mill near Gold Hill, and 2½ acres of land has already been donated for the purpose. It will be large enough to treat all the ore of the district, and if the project is carried out it will greatly aid the development of the many prospects of the county. T. D. Stoner reports that a 5-ft. seam of coal of good quality has been uncovered two miles north of Moonville.

JOSEPHINE COUNTY

The 5000-lb. display of gold and copper ore from Josephine county won first honors at the Northwest Mining Congress held at Spokane recently. H. G. Siskron recently cleaned up 52 oz. of bullion, worth \$18 per oz., from a

mill-run of 12½ tons of ore at the January First mine on Sucker creek, 4 miles from Holland. The property was located in 1905 and has several hundred feet of development work.

UTAH

EMERY COUNTY

The Utah Coal & Coke Co. has been incorporated to develop 2000 acres of coal lands which it owns in this county. J. R. Sharp is president of the company. While the property is about 50 miles from a railroad, it is hoped that coal from it can reach the market by spring. Shipment will be by way of Price, Carbon county.

JUAB COUNTY

The 400-hp. electric-driven hoisting engine for the Iron Blossom, furnished by the Nordberg Mfg. Co., will be delivered soon and will facilitate production from the lower levels. The Dragon is mining ore of 5 to 10% copper and 20 to 50 oz. silver on its 600-ft. level. The Eagle & Blue Bell shaft was sunk 200 ft. between January 8 and February 20, and will be continued to the 1400-ft. level. The Tintic Min. & Dev. Co. has installed a 50-hp. electric-driven hoist in one of the cross-cuts from its main adit, 200 ft. from the portal. Shipments from the district for the week ended February 22 were, in carloads: Iron Blossom, 52; Centennial Eureka, 46; Chief Con., 13; Colorado, 12; Yankee, 11; Gold Chain, 10; Grand Central, 9; Mammoth, 9; Eagle & Blue Bell, 6; Gemini, 5; Beek Tunnel, 4; May Day, 4; Victoria, 4; Opohongo, 4; Sioux Con., 3; Enreka Hill (lease), 2; Swansea (lease), 1; Dragon Iron, 1; Sioux mill dump (Depue lease), 1; Scranton, 2; a total of 200.

SALT LAKE COUNTY

The Utah Copper Co. has declared a dividend of 75c. per share, payable March 30 to stock of record March 8.

The Ohio mill has handled 2400 tons per day with 16 of the Wall rolls in operation. The ore now being milled averages 1.3% copper.

Three ore-cars ran away just below the ore-bins of the Utah Copper Co., on February 15, and jumped the track just above the business section of Bingham. Two buildings were demolished and four men killed, two of them members of the train crew, and eight persons were injured.

The Montana-Bingham Con. M. Co. has been incorporated and will take over 300,000 shares of Montana-Bingham stock. Agreements have been made with the Bingham Amalgamated, Congor, Fortuna, and Starless. Work in the adit is being pushed, and it will be driven 400 ft. farther. At the Highland Boy back-filling of stopes is being employed to prevent caving. Waste is being employed for the purpose, thus making a saving in its handling.

SUMMIT COUNTY

The new loading station of the Daly West is finished, and when the water and ore-supply are increased the mill will be operated on 3 shifts again. The annual meeting of the company was held at Denver, February 15. The mine is now producing 900 tons of shipping ore per week. The dividend of \$67,500, paid in January, makes the total to date \$6,322,500. The East Ontario meeting was held at Park City, February 20, and the old board of directors, J. H. Dieter, S. B. Sebnlyer, E. M. Curtis, A. Ramel, and J. B. Allen, were elected. Mr. Allen is manager for the company and made an optimistic report. Driving is expected to resume in the Snake Creek drainage adit by March 1, as the concrete work in the bad ground should be finished by that time. Steel rails have been used for reinforcement.

WASHINGTON

SPOKANE COUNTY

At the meeting of the Spokane section of the A. I. M. E., on February 17, R. S. McCaffery, professor of mining at the University of Idaho, presided. Among the papers presented were 'Mining Methods at Nacozari,' by D. C. Livingston; 'Replaceable Lips for Elevator Buckets,' by A. Maguire; 'Surveying Under Difficulties,' by C. H. Loux.

CANADA**BRITISH COLUMBIA**

The British Columbia Copper Co. made a net profit of \$134,000 during 1911, nearly all of it in the last four months of the year. The company is now working properties of the New Dominion Copper Co. which furnish one-third of the ore now being smelted at the Greenwood smelter. The Granby smelter is increasing its output of blister copper; 2,589,000 lb. has been shipped so far this year. The Canadian Consolidated has secured the property on Five-Mile creek, where rich ore was recently found. At the Granite Poorman, recent development work has shown encouraging results. Minneapolis people have taken over the Second Relief mine and mill, near Erie, and they are again in operation.

ONTARIO

The Temiskaming squabble has been settled, but a fight now threatens over the Trethewey. The annual report of that company shows total receipts of \$372,622, as compared with \$427,522 last year, and net revenue of \$160,306, which is \$77,494 less than in 1910 and \$39,500 less than in 1909. The shareholders threaten to reduce the recently increased capital back to \$1,000,000, to employ a consulting engineer, and to make public monthly statements of returns. At the meeting, held February 28, a lively time was expected. The Trethewey recently shipped 1983.48 oz. of bullion, worth \$1155, and the Nipissing 24,385.3 oz., worth \$14,174.

MEXICO**HIDALGO**

The Compania Minera y Beneficiadora de Maravillas y San Francisco, of Pachuca, paid a dividend of \$2 per share on February 25. The new Walker Bros. 250-hp. compressor on the La Blanca y Anexas property has been placed in commission.

OAXACA

L. R. Wilfley, of Mexico City, and associates have purchased from C. A. Hamilton his interest in the San Juan mine, Taviche district. It is reported that the new owners are planning the construction of a large mill. The San Juan property has been operated by the San Juan M. Co., and before the recent sale steps had been taken for the construction of a 200-ton concentrator, to treat the low-grade ore from the mine. Mr. Hamilton has purchased the Santa Gertrudis hacienda, one of the best agricultural properties in the Oaxaca valley.

SONORA

(Special Correspondence.)—W. T. Calderwood, president and general manager of the Mexico Mining, Refining & Exploration Co., which owns several promising properties in Sonora, one of them being the Creston de Cobre, 30 miles west of Hermosillo, and the other, La Cobriza, in the Sahuaripa district, states that the Creston de Cobre has been prospected and developed for a number of years and now has over 2000 ft. of actual development work done on it, and during recent operations a large body of ore was found, the vein being 27 ft. wide at 500 ft. in depth. The average content of this is over \$15. In addition to the equipment which the company already has, it is installing a 90-hp. compressor and two 65-hp. tandem boilers to put on enough air-drills to start producing 100 tons of ore per day. In view of this promising showing on the property, the company will in the near future install its own smelter at the mine.

Hermosillo, February 15.

CHIHUAHUA

(Special Correspondence.)—A committee of local shareholders in the San Toy Mining Co. has sent out printed circulars to all the shareholders, alleging that for the past year and a half a part of the machinery and equipment of the company has been used by private interests without any return to the company. Donald B. Gillies, general manager of the San Toy, and associates have a lease upon the Quince de Mayo, which adjoins the San Toy, and can only be worked profitably through the San Toy ground. Re-

cently it has been stated that \$12,000 to \$15,000 has been paid on account of the lease, and the local shareholders claim that the affairs of the company are not being properly managed and have asked for proxies to oust the present board of directors from control.

Chihuahua, February 10.

Among the Copper Mines

IN THE NORTH BUTTE, on the 200-ft. level of the Snowball, it is reported that the vein is over 8 ft. wide, averaging 15 to 20% copper.

THE COPPER QUEEN, in exploring from its Spray shaft, has found a large body of rich sulphide ore within 18 ft. of the Calumet & Arizona boundary.

THE CHINO, according to its monthly report, is producing copper at a little over 8c. per pound, with only two units out of five in operation. Each of these is handling

CHINO MILL, WHILE UNDER CONSTRUCTION.

nearly 1000 tons per day of ore varying from 2.2 to 3% copper. The plant is making an average extraction of 70%. Good progress is being made in opening the pits, and in two or three months time the mine will be in shape to produce 5000 to 7000 tons per day.

THE UNITED VERDE COPPER Co. has advertised for bids for the construction of 6 miles of broad-gauge railway to the new smelter site from the 1000-ft. adit. The company has purchased a number of farms which might be damaged by the fume from the new plant, and these will be managed by W. A. Jordan. The new plant will have a capacity of 6,000,000 lb. per month and will be a purchaser of silicious ores. Charles W. Clark is manager.

THE NEVADA CONSOLIDATED has four steam-shovels at work on overburden in the Copper Flat pit, and one on ore. In the Liberty pit one shovel is at work on ore and one on overburden. A new 95-ton Bucyrus shovel is being assembled and tested at Ruth. At the Veteran, more than 300 men are at work, and a trainload of ore per day is being sent to the Steptoe mill. The ore from the Liberty pit is said to be higher grade, and with the Veteran ore will materially increase the copper content of the mill feed.

THE ARIZONA COPPER Co. has approximately 175 men at work in its new plant. Of these, 75 are grading and the rest shifting the line of the A. N. & M. railroad 30 ft. to the north. The contract for the steel work has been let to the Kansas City Structural Steel Co., and delivery is promised for May 1. A temporary power-plant has also been contracted for. The stack of the new plant will be 22 ft. diam. at the base and 300 ft. high. The roasters will be of the Herreshoff air-cooled type, and have already been contracted for. The copper production of this company during January was 3,200,000 pounds.

LOCAL METAL PRICES

San Francisco February 29.

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

Antimony	11-11½c	Quicksilver (flask)	46.50
Electrolytic Copper	16-17½c	Tin	47-48½c
Pig Lead	4.25-5.20c	Spelter	8-8½c

Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50

METAL PRICES

(By wire from New York.)

Average daily prices in cents per pound, based on wholesale transactions, standard brands.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Feb. 22	Holiday.	No market.		
" 23	14.28	4.00	6.55	58½
" 24	14.33	4.00	6.55	58½
" 25	Sunday.	No market.		
" 26	14.33	4.00	6.60	58½
" 27	14.33	4.00	6.60	58½
" 28	14.33	4.00	6.60	58½

SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.		1911.	1912.
Jan.	54.33	56.05	July	52.57
Feb.	52.23	59.06	Aug.	52.17
Mch.	52.76	Sept.	52.43
Apr.	52.32	Oct.	53.37
May	53.31	Nov.	55.77
June	53.04	Dec.	51.45

LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.		1911.	1912.
Jan.	4.49	4.43	July	4.50
Feb.	4.44	4.03	Aug.	4.50
Mch.	4.39	Sept.	4.48
Apr.	4.41	Oct.	4.27
May	4.37	Nov.	4.30
June	4.34	Dec.	4.45

ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan.	5.47	6.42	July	5.70
Feb.	5.52	6.50	Aug.	5.95
Mch.	5.56	Sept.	5.86
Apr.	5.10	Oct.	6.10
May	5.35	Nov.	6.38
June	5.50	Dec.	6.30

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations in dollars per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan.	44.60	43.75	July	48.00
Feb.	48.40	46.00	Aug.	50.00
Mch.	52.50	Sept.	47.50
Apr.	50.90	Oct.	46.12
May	46.50	Nov.	45.50
June	46.50	Dec.	44.50

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	41.25	42.53	July	42.40
Feb.	41.61	43.00	Aug.	43.32
Mch.	40.16	Sept.	39.75
Apr.	42.18	Oct.	41.18
May	43.11	Nov.	43.12
June	44.61	Dec.	44.65

COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	12.39	13.92	July	12.47
Feb.	12.59	14.10	Aug.	12.41
Mch.	12.14	Sept.	12.20
Apr.	12.02	Oct.	12.19
May	11.99	Nov.	12.61
June	12.39	Dec.	13.89

COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

	U. S.	Foreign.	World.
January 1909	122,357,266	124,716,480	247,073,746

Firebrick:		
Bauxite, $\frac{1}{2}$ M	175.00	
Magnesite, $\frac{1}{2}$ M	190.00	275.00
Silica, $\frac{1}{2}$ M	42.50	47.50
Flint pebbles for tube-mills, $\frac{1}{2}$ 2240 lb.	16.50	22.50
Fluorspar, $\frac{1}{2}$ ton	10.00	15.00
Fallers earth, according to quality, $\frac{1}{2}$ ton	20.00	30.00
Gilsonite, $\frac{1}{2}$ ton	35.00	40.00
Graphite:		
Amorphous, $\frac{1}{2}$ lb.	0.01 $\frac{1}{2}$	0.02 $\frac{1}{2}$
Crystalline, $\frac{1}{2}$ lb.	0.04	0.13
Gypsum, $\frac{1}{2}$ ton	7.50	10.00
Infusorial earth, $\frac{1}{2}$ ton	10.00	15.00
Magnesite, crude, $\frac{1}{2}$ ton	7.50	10.00
Magnesite, dead calcined, $\frac{1}{2}$ ton	23.50	27.50
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, $\frac{1}{2}$ ton	10.00	25.00
Manganese, prepared, according to quality, $\frac{1}{2}$ ton	30.00	70.00
Mica, according to size and quality, $\frac{1}{2}$ lb.	0.05	0.30
Molybdenite, 95 $\frac{1}{2}$ MoS $_2$, $\frac{1}{2}$ ton	100.00	500.00
Monazite sand (5 $\frac{1}{2}$ thorium), $\frac{1}{2}$ ton	150.00	200.00
Nickel metal, refined, $\frac{1}{2}$ lb.	0.15	0.60
Ochre, extra strength, levigated, $\frac{1}{2}$ 100 lb.	2.25	3.25
Platinum, native, crude, $\frac{1}{2}$ oz.	40.00	45.00
Sulphur, crude, $\frac{1}{2}$ ton	15.00	25.00
Sulphur, powdered, $\frac{1}{2}$ ton	40.00	45.00
Talc, prepared, according to quality, $\frac{1}{2}$ ton	20.00	50.00
Tin ore, 60 $\frac{1}{2}$, $\frac{1}{2}$ ton	450.00	475.00
Tungsten ore, 65 $\frac{1}{2}$, $\frac{1}{2}$ ton	155.00	500.00
Vanadium ore, 15 $\frac{1}{2}$, $\frac{1}{2}$ ton	150.00	180.00
Wolframite (see tungsten ore).		
Zinc ore, 50 $\frac{1}{2}$ up, $\frac{1}{2}$ ton	*15.00	20.00

Company Reports

ATBASAR COPPER FIELDS, LTD.

This company, which is closely affiliated in management with the Spassky Copper Mine, Ltd., and operates mines and smelters in the Khirgiz steppes of Siberia, 230 miles northeast of Djoussalie, on the Orenberg-Tashkent railroad, and 600 miles south of Petropavlovsk, on the Trans-Siberian railroad, was organized in London in 1906 with a capital of £250,000 in £1 shares, and in March 1911 the capital was increased to £500,000. The company is in process of development. R. Gilman Brown has reported upon the property, finding 389,000 tons of ore proved, containing copper of a gross value of £3,000,000. During 1911 W. G. Perkins reported upon the possibility of erecting a smelter, and during 1912 a first unit of 100 tons per day capacity, estimated to cost £50,000, will be erected. H. C. Woolner, general manager for the Spassky company, has been appointed local director of the company, and the Spassky company has an option upon 200,000 of the unissued shares of the Atbasar company.

GIROUX CONSOLIDATED MINES CO.

This company, with properties adjoining those of the Nevada Consolidated, near Ely, Nevada, was organized in 1903, with a capitalization of \$5,000,000, which has since been increased to \$7,500,000, all issued with the exception of \$496,400 retained to retire an issue of 6% convertible first and second debenture bonds. The company owns 249,575 of the 500,000 shares of the Butte & Ely Copper Co. The property is in the development stage, and the report for the year ended December 31 shows that the company has 10,291,000 tons of fully and partly developed ore of a copper content of 2%, and 6,600,000 tons more of an average content of 1.65%. In the Morris-Bunker Hill mine there are 4,010,000 tons of ore averaging 2.14% copper. During the year the Giroux shaft was damaged by fire, but damage has been repaired at a cost, so far, of \$34,521. A contract has been made with the Steptoe Valley Mining & Smelting Co. to ship to the concentrating plant of that company not less than 600 tons, nor more than 1200 tons daily of ore, which will be treated by this company at a rate which it is estimated will correspond to a production cost of 9½¢. per pound of copper. This contract goes into effect May 1, 1912, and is for a period of five years.

COROCORO UNITED COPPER MINES, LTD.

This company, which operates mines in the Corocoro district, south of La Paz, Bolivia, was organized in London in 1909 with a capital of £700,000, of which 279,657 shares of £1 each have been issued. During the year ended June 30, 1911, some 67,000 tons of ore was produced by the Santa Rosa, Guallatire-Grande, Viechani, and Toledo mines. The Toledo mine is now closed. The ore was band-dressed to 47.481 tons of 3.36% ore, in which the copper appears chiefly in the form of the native metal, with very subordinate amounts of chalcocite and domeykite. The mills, of which there are three, one at each mine, produced 2038 tons of concentrate containing 77.38% copper, which is shipped to Europe. The cost of production of the copper is given as £47 12s. 2d. (£37 13s. mining and milling, £1 6s. 9d. export duty, £4 12s. 6d. transport to coast, £2 2s. freight to Europe, £1 18s. selling commission). The district is arid and without timber, and the remote and inaccessible situation of the mines renders working costs high. It is expected to connect the mines by a branch line to the railway to Arica, when the oxidized ore will be treated. The net profit on the year's operations was £9906, making a balance of £14,382, from which it is intended to write off £6260 for depreciation and £7000 for preliminary expenses of formation of the company. These mines have been productive of copper for a great number of years, and are popularly supposed to have been worked by the Incas.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE ECONOMICS OF MINING FINANCE. By M. H. Burnham. Pp. 26; ill. Reprinted from *The Mining Magazine*. For sale by the *Mining and Scientific Press*. Price 50c.

This is a reprint of a series of articles which, under the title of 'The Finance of a Mine', attracted much attention at the time of their publication in *The Mining Magazine* during 1911. The author's discussion of this topic is profound, and indeed is perhaps, in many instances, above the heads of his readers, who are apt to be appalled by such impressive formulæ. And in putting mine finance upon a sound basis, he is also inclined to be too strict, from a business standpoint. These are the criticisms of excellence, however, and Mr. Burnham's able exposition of a subject too frequently shrouded in profound mystery will be of the greatest service and interest both to engineers and investors.

ENGINEERING AS A VOCATION. By Ernest McCullough. Pp. 201. David Williams & Co., New York, 1911. For sale by the *Mining and Scientific Press*. Price \$1.

The author of this interesting volume has written, out of a wide experience, a book which is intended for the high-school student about to choose a vocation, and for his parents. It consists of six chapters upon the engineer, the work of the engineer, the education of the engineer, home-study courses, how to hunt and hold a job, and whether it pays to study engineering. In an appendix to the volume the author admits that the chief reason for the preparation of the book was to secure the publication of the concluding chapter, which had been refused by several civil engineering journals as not sufficiently optimistic in tone. As a matter of fact, the author, while somewhat cynical, is eminently fair and open-minded. A perusal of the book can safely be recommended to all parents and youths, as an antidote to much of the drivel that is published in newspapers and non-technical journals as to the opportunities and rewards of the engineer. To the conclusion that the majority of students should receive a professional training in either engineering, law, or medicine, and then utilize this as the equipment for whatever vocation may open to them, rather than swelling the ranks of those who merely mark time in their profession, many will be inclined to agree.

THE METALLURGY OF IRON AND STEEL. Vol. I and II. By F. W. Harbord and J. W. Hall. Pp. 933; ill. Chas. Griffin & Co., London, 1911. For sale by the *Mining and Scientific Press*. Price \$12.

The first edition of this well known work appeared some years since, and was so well received that the present is the fourth edition. With each revision the work has gained in size until it now appears in two volumes, for convenience in use. This is admirable, for the second volume, on the mechanical treatment of steel, by J. W. Hall, is the best presentation of the topic available in any language, and many will wish to possess it, even though not steel metallurgists. This treatise is too well known to need an extended review, and it will suffice, therefore, to mention those features in which the fourth edition differs from the third. In the first volume new drawings illustrate the late modifications in open-hearth furnaces, charging machines, and gas producers, while basic open-hearth practice and electric smelting are rediscussed in the light of recent developments, and plans of new plants in America and Europe are given. The volume on mechanical treatment has been revised throughout, and new chapters on exhaust steam turbines, the generation of steam by solid fuel and waste gases, the production of power by gas-engines using blast-furnace gas, and the electric driving of mills have been added, so that what was already the best is further improved. It is the most readable of all the larger works on steel.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

MINER'S LIEN—WHO ENTITLED TO

A person employed by a mining company as general manager and superintendent, and who has charge of mining operations which require his personal supervision, and require him to perform personal manual labor, and who actually performs manual labor upon the mining claim, for the benefit, development, and operation of the property, is entitled to a lien under the statute of South Dakota which provides that every miner or other person who at the request of the owner of the mine shall perform labor on such mine shall have a first lien thereon prior to other liens. The fact that such person was a stockholder and director of the mining company does not preclude him from being employed by it and from being entitled to the lien, though he had received other moneys from the mining company as payment for commission on the sale of corporate stock made by him, where he claimed no lien on account of such commissions.

Hahn v. Anaconda Gold Mining Co., (South Dakota)
128 Northwestern, 128. October 1910.

DISCRIMINATION IN FACILITIES FOR SHIPMENT OF COAL—DAMAGES

A common carrier is liable for an illegal discrimination for furnishing transportation facilities for shipment of coal, and in an action for such discrimination the measure of damages is what would be a reasonably fair profit on the fairly probable output of the mine discriminated against, less what was actually shipped from the mine. And the fact that coal belonging to the coal company was left in the ground and might be available for future shipment is immaterial on the question of damages, in the absence of proof of what the coal company would realize for such coal if shipped in the future as much as it would have realized if shipped during the period of the alleged illegal discrimination.

Hillside Coal & Coke Co. v. Pennsylvania R. R. Co.,
(Pennsylvania) 78 Atlantic, 28. July 1910.

OPTION CONTRACT FOR THE PURCHASE OF A VEIN OF COAL—ACCEPTANCE

An option for the sale and purchase of a certain vein of coal and mining right, called for final acceptance by a specified day, and gave the vendee the right thereafter to object arbitrarily to the quality of the coal, the character or location of the surface, or to any title or conveyance, or to the terms of mining rights, and if the vendors were unable or unwilling to remove the same, then either party had the right to rescind the sale. In an action to enforce the contract it was held that after a final acceptance by the vendee, investigation of the coal, coal beds, surface and mining rights, and the final election to take the property agreeably to the terms of the contract, and calling for abstracts of title and deed, the vendee thereby waived the right to interpose such arbitrary objections, and upon tender of abstracts of title and a deed conveying a good title and reasonable and adequate mining rights, the vendors are entitled to specific performance of the contract. And the fact that the vendor was not the actual owner, but was the agent of the owner, and represented the owner as agent, all of which the purchaser well knew, is not such lack of mutuality as will excuse specific performance by the purchaser, where it is shown that the purchaser knew the authority and contract of the vendor had been ratified by the owner.

Armstrong v. Maryland Coal Co., (West Virginia) 69
Southeastern, 195. October 1910.

The Earle Power Co., of Salt Lake, has filed its articles of incorporation, with a capitalization of \$250,000, of which \$75,000 has already been subscribed.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

L. D. HUNTOON is now in Missouri.

F. L. SIZER has gone to Plumas county.

A. C. VEATCH has been in San Francisco.

A. W. PRIOR has returned to Los Angeles.

RALPH ARNOLD was in San Francisco last week.

J. D. HUBBARD is expected in San Francisco next month.

W. S. KEITH has returned to San Francisco from Placer county.

H. W. TURNER was in San Francisco and has returned to London.

T. A. RICKARD is expected in San Francisco at the end of March.

H. W. METCALFE has left England for the Federated Malay States.

R. Y. HANLON expects to return to the United States from Manila shortly.

J. S. WILSON has been elected a director of the Dome Mines Company.

J. W. FINCH is lecturing on economic geology at the University of Chicago.

W. C. DE CAMP is in charge of the Creede Triune Mines Co., of Creede, Colorado.

MALCOLM MACLAREN returned from Cordova to Seattle and has gone to Juneau, Alaska.

E. S. BERRY is on his way to Chile to inspect the properties of the Braden Copper Company.

WILLIAM H. HENDRICKSON is now manager for the Horn Silver Mining Co., at Frisco, Utah.

WALLACE BROAD is on his way to Changsha, Hunan Province, China, by way of Siberia.

W. H. STORMS has returned from Bakerfield, where he has been studying conditions in the oilfields.

B. R. BATES is now with the El Rayo Mining & Developing Co., S. A., at Santa Barbara, Chihuahua.

GEORGE D. JAMES has opened an office as consulting engineer at 1103 Boston building, Salt Lake City.

S. E. BRETHERTON has returned from a professional trip to Winthrop, Shasta county, California.

GEORGE G. VIVIAN is manager of the Pittsmont plant of the East Butte Copper Mining Co., Butte, Montana.

ROSS E. BROWNE is recovering nicely from an operation which he recently underwent at the Adler Sanitarium.

GEORGE J. HOUGH has sold his assay business at Salida, Colorado, and is engaged with a mining company in Zacatecas, Mexico.

H. V. WINCHELL was in San Francisco early in the week and has gone to Toronto to attend the meeting of the Canadian Institute.

H. KENYON BURCH is at Globe, Arizona, on professional business. He has opened offices as mechanical and metallurgical engineer at 503 Union Oil building, Los Angeles, California.

Obituary

WILLIAM ASHLEY WHITLEY, one of the California pioneers, died in San Francisco on February 23 of pneumonia. He was 72 years of age, having come to California from Missouri in 1861. During the years that followed he was prominent in mining on the Comstock and elsewhere in Nevada, California, and Montana. He was a close friend of George Hearst, and was an intrepid explorer and adventurer. During recent years he was engaged in the contracting business in San Francisco, where two sons and two daughters survive him.

Recent Publications

MASSACHUSETTS INSTITUTE OF TECHNOLOGY. CATALOGUE. 500 pp. Boston, 1911.

GEOLOGIE DU CANTON DE FABRE, COMTE DE PONTIAC. By Robert Harvie. Bureau of Mines, Province of Quebec. Pp. 36. Quebec, 1911.

CHINA: SOCIAL AND ECONOMIC CONDITIONS. Annals of the American Academy of Political and Social Science, Vol. XXXIX, No. 128. This volume consists of a series of sixteen articles upon various topics of present interest regarding China, and in view of the widespread attention attracted by recent political changes in that country, is likely to be of much service. The articles are of very unequal value; Arthur H. Smith writes informally of reconstruction in China and contributes the best of what is new, as the articles by Frederick McCormick and B. Lenox-Simpson (Putnam Weale) have previously appeared. Several articles by Chinese students in American universities derive their chief interest from their authorship, while the articles by Hawkes-Pott, Hinekey, Edwards, Cadbury, and Anderson are excellent discussions of special topics. The article on the geography and resources of China is so poor that it seems remarkable that the author of it could not have done better with the aid of the books of reference which he cites.

Catalogues Received

ALLIS-CHALMERS Co., Milwaukee, Wisconsin. Bulletin No. 1801. 'The Isbell Vanner.' 20 pages. Illustrated. 8 by 10 inches.

ALBERGER PUMP Co., 140 Cedar St., New York. Catalogue D. 'Centrifugal Pumps and Steam Turbines.' 72 pages. Illustrated. 6 by 9 inches.

SEAGER ENGINE WORKS, Lansing, Mich. 1912 Catalogue. Describing the Olds gasoline engines for industrial use, traction engines, and mine hoists. 48 pages. Illustrated. 6 by 9 inches.

RUGGLES MACHINE Co., Poultney, Vermont. Catalogue describing this company's aerial carrier. These carriers will run on an inclination of 15% on a fall of 1 ft. in 15 ft. on short cables. The carrier will lift a load from any depth to the cable, when the carrier is automatically and instantly released and sent on its way to the desired spot where the load is automatically dumped, or lowered to the ground according to the manner in which the dumping hooks are arranged by the men in the pit. One engineer can manipulate three of the carriers on as many cables with a three-drum engine. They are also used for stripping and conveying material of all kinds. This catalogue is well prepared and will be sent on request. 30 pages. Illustrated. 7 by 10 inches.

INTERNATIONAL MOTOR Co., Broadway and 57th street, New York. This company is a consolidation of the Mack Motor Co. and the Saurer Motor Truck Co. Very attractive catalogues have been issued covering the Mack truck as well as the Saurer, showing the extensive field for motor-driven vehicles, particularly for delivery purposes and heavy trucking. The Saurer motor truck during 1911 was given an exceedingly severe test, as a 4½-ton truck carrying 7000 lb. traveled from the Atlantic to the Pacific Coast, over 5263 miles, with no mechanical trouble. This trip was over good roads and bad roads, as well as over miles of desert country. The numerous illustrations in the catalogue cover the use of motor trucks in a great many industries as well as for overland travel and through mountainous country. It is claimed by the International Motor Co. that during the past 10 years, Saurer trucks have won 53 first prizes in European government and automobile club contests and that they have won every event and every contest entered. Motor-truck transportation is rapidly displacing the horse; and anyone interested in this subject will find much of value in these attractive catalogues, which will be sent on request.

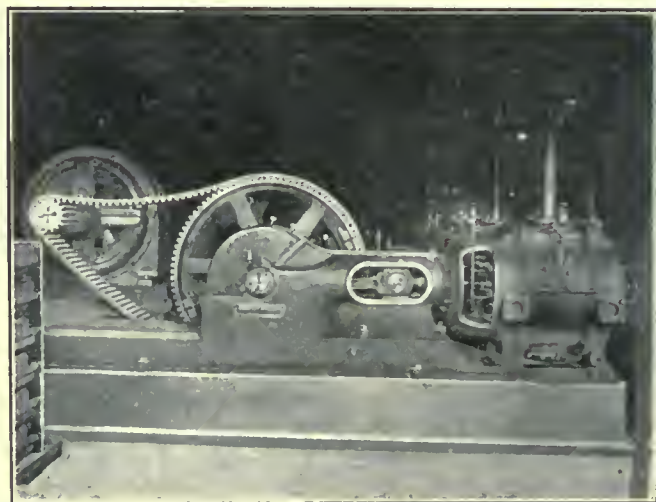

Commercial Paragraphs

The WATT MINING CAR WHEEL Co., Barnesville, Ohio, announces that it is no longer represented by Ira E. Stevens or the Stevens Mine Car Co. of Chicago, Illinois, and that in the future all inquiries and orders will be handled direct from Barnesville.

A. C. VEATCH, having returned from a year's examinations and explorations in the Trinidad and Venezuela oil-fields, and having resigned from the United States Geological Survey, where he was geologist and chairman of the Land Classification Board, announces that he will practise as a consulting geologist, specializing in oil, with an office at 3415 Ashley terrace, Washington, D. C.

T. R. BROOKS, for 15 years with the Risdon Iron Works and of late with the Union Iron Works, has resigned from the latter concern and with W. E. MUSHET has formed a partnership under the name of the W. E. MUSHET Co. This firm will have offices in the Hooker & Lent building, San Francisco, and will act as manufacturers' agents for mining machinery, steam-plant equipment, and similar lines.

The accompanying illustration shows one of three 125-hp. maximum silent chain drives recently furnished the Illinois Pacific Glass Co. by the MEESE & GOTTFRIED Co. of San Francisco. The chains are 9 in. wide, 2-in. pitch, and run

at a speed of 1560 ft. per minute, driving Dow double-acting duplex air-compressors for supplying compressed air to the various departments of the factory. Sprocket wheels on air-compressors are 5 ft. diam., those on the motors being 11 in. diameter.

A deal of considerable interest in machinery circles has recently been made whereby the WISCONSIN ENGINE Co., of Corliss, Wisconsin, has acquired the United States rights for the manufacture and sale of the Grine-Nelles crude oil gas producer, formerly owned by the Gas Power Machinery Co., of Los Angeles, California. The negotiations which have extended over a period of some months were conducted by Fred C. Nelles, president of the Gas Power Machinery Co., and E. T. Adams, president of the Wisconsin Engine Co., and were closed in Chicago about two weeks ago. The apparatus was developed and demonstrated in Los Angeles, where it has been in operation successfully for the past year on the low-grade California oils. A carbonaceous fuel bed overcomes the difficulties heretofore encountered in all attempts to develop a producer that would operate continuously on crude oil. Under the Grine-Nelles system regular twenty-four hour a day service is maintained with a single shell, and very remarkable economies have been secured. Edward A. Rumely, of M. Rumely Co., will be associated with the Wisconsin Engine Co. in actively entering the market wherever cheap oil can be obtained, and W. K. Thompson, 705 Union Oil building, Los Angeles, California, is Western sales manager.

EDITORIAL

PERHAPS that \$70,000,000 promoters' fee had nothing to do with the increased cost of living—and perhaps it did.

TESTS made at the experimental mine of the United States Bureau of Mines confirm the suggestion that rock dust may be used to localize the effects of a coal-dust explosion in mines, and point the way to markedly decreasing danger from this source.

REVIEW of the action of the United States Circuit Court of Appeals in the case of the farmers against the smelter at Anaconda, Montana, is promised. The conclusion may not be better founded but it will be final. There is much in the remark of the State House janitor that "the supremacy of the Supreme Court consists mostly of the lastness of its guess."

TRADE between the United States and the Philippine Islands has shown a steady growth during the past decade and has now reached the pleasing sum of over twenty million dollars worth of imports, and exports of equal value. Imports consist chiefly of sugar, manila fibre, copra (cocoanut meat), tobacco, and hats, while exports from the United States are chiefly manufactured articles, supplemented by foodstuffs. Mining shows encouraging growth, as set forth in the letter from our Manila correspondent, who, with true Western spirit, is inclined to regard the doughnut rather than the hole. Development in the Philippines has been hampered by natural conditions, as well as by the operations of those who were more concerned with the advancement of personal fortunes than the development of industry, but the outlook seems to be brightening.

ADVANCE in silver prices will require many readjustments in industrial circles. It has been estimated that the recent rise corresponds to an increase of over \$2,000,000 in the income of the leading producers in North America, while exchange between the United States and countries upon a silver basis has risen nearly 15 per cent since last autumn. This operates seriously to the disadvantage of the new Chinese republic, which will have to pay for its loan of 20,000,000 taels almost 15 per cent more than would have been necessary six months earlier. China will require large sums in silver to meet the cost of the recent outbreak, while later industrial expansion, if the hoped-for changes are brought about, will continue the demand. India is expected to be a heavy buyer, so it is not unreasonable to expect that later in the year silver will reach the price it commanded early in 1907.

DURING a discussion, not long since, at one of the meetings of the Institution of Mining and Metallurgy, a distinguished member whose name we will forbear mentioning, in speaking of our knowledge of the genesis of metallic ores said that it "has been illuminated by the geographic [?] work of L. deLannay, Malcolm MacLaren, and some American workers." This might be humorously cited as an example of extreme British conservatism, were it not that a similar tendency to slur over the work of others is all

too common on this side of the Atlantic as well. It is a remarkable fact that scientific men, even those of the highest attainments who might reasonably be expected to give every fact its due weight, show a deplorable tendency to cite the conclusions of other workers when they can be shown as fallacious, but to ignore the results of those who were correct. In children this would be ascribed to the psychology of adolescence, in grown men of scientific attainment and supposed intellectual honesty it is an unnamable but unfortunate phenomenon. There is credit enough for all; honor is a commodity of which the supply is not decreased by free use. A more generous spirit among scientific workers would lead to better feeling among those with whom *noblesse oblige* should be a guiding principle.

STEALING gold is a pleasant pastime too common among miners. There are few districts in which specimen ore occurs and in which there is no trouble. In Gilpin county, Colorado, operators are now making an effort to stop the illicit traffic. At Grass Valley distinct progress has been made in that Mr. George W. Starr recently secured the conviction of one thief. Juries can seldom be found that will bring in a verdict of guilty, but repeated trials have at last aroused the public conscience of the community. It is one of the distressing features of this traffic that the 'ignorant foreigner' is by no means the worst offender and that the thieves often have connections higher up. There is but one permanent cure, and that is development of a sound public opinion such as is present, even if sometimes latent, in every American community. Keep everlastingly at it, Gentlemen, despite the discouragements that too often follow attempts to secure justice. Thieves have no place in American life, whether in the stope, the counting room of 'high finance,' or on the public highway.

BOLIVIA has long been famous as a producer of silver and gold. The bonanzas of Potosi take second rank only to those of Guanajuato, and it has been estimated that between 1545 and 1800 there was coined from their output over 800,000,000 Spanish dollars, with an equal amount from other sources. More recently its tin resources have become prominent, the Bolivian production of that metal only being surpassed by the output of the Malay peninsula and adjacent islands. Gold mining has been less developed, though *lavaderos* have existed from early times. Recent discoveries have served to largely increase the importance of these, and interest in Bolivia has been greatly stimulated, especially upon the Pacific coast. We are fortunate in being able to present this week an authoritative article by Mr. Carlos Sanjines, Consul for Bolivia at San Francisco. Mr. Sanjines gives useful information as to mining regulations and cost of travel, to which we may add that letters from those already in the field report encouraging results, but urge that prospectors should not make the venture without an ample grubstake. Bolivia is a fine habitable country where large areas are open to prospecting under much less hardship than must be incurred in many parts of the United States. Living is good, the people are friendly, and a number of rivers have already been sufficiently prospected to prove the presence of rich placers.

ABOLITION of discovery as a precedent to location of mineral claims, is suggested in the informing article prepared by Mr. H. V. Winchell for the Canadian Mining Institute that we print this week. Discovery and apex rights were originally linked on the basis that a prospector, having found mineral, should be entitled to the whole of the find, while land not actually mineral in character should be reserved for other use. The principle is good, but in practice both discovery and apex rights introduce complications and are, we believe, likely to be abandoned. In the case of oil,

deep placers, and many lode claims, actual discovery is impossible without such expenditure as should be given protection. It has been said that genuine discovery of the Anaconda vein would have required a shaft 200 feet deep. At Ely, on many claims, the orebodies were covered by ten feet or more of solid limestone. Obviously in these cases no real discovery could be made at the surface. In practice it was long common to set up a stake without discovery, and until the Forest Service and Land Office became active and inquisitive, any bit of mineral answered the requirements. The many difficulties incident to rival claims under these conditions have imposed a serious tax on development. It would be much simpler to do away with the requirement of discovery and allow any ground to be staked, and to stiffen the requirements as to regular and continuous working so as to make it unprofitable to hold ground which is really non-mineral in character. Mr. Winchell's paper contains much food for thought. We shall follow it with others bearing on the subject, and hope that all points of view will be presented while the general subject of revision of the mining law is being discussed.

Smelter Fume in Japan

When facing an intricate problem it is always interesting, and often profitable, to learn how your neighbors have met the same difficulties, and in the treatment of smelter-fume help from every source is desirable. In densely settled countries with well developed industries, such as the Eastern part of the United States, and Europe, it is possible, by finding a market for sulphuric acid, to dispose of the sulphur in the fume economically and satisfactorily. In Utah, Montana, and California this is only feasible on a limited scale. There is no present or imminent market for the sulphuric acid that might be made at Anaconda alone, and, if it were economically possible to ship acid from Montana to the Eastern states, this would merely result in disorganization of established industries. It is unnecessary to review here the various attempts made in the Western states to meet the difficulties of an admittedly serious situation. These have been chronicled from time to time in our news pages, and while there is distinct promise of final relief, it is fair to say that at present no entirely satisfactory means of handling smelter fume in the states mentioned has been devised. The final solution must be a process which prevents escape of injurious material from the stack, and which is applicable if not with profit, at least without serious loss to the smelting company.

Pending perfection of existing processes or invention of better ones, and owing to our imperfect methods of legal procedure, it has been customary to close the offending works by injunction. In determining whether such injunction shall be made permanent, the relative measure of damages is not, unfortunately, the principal factor. It should be clear that closing a smelter cuts off the revenue from the only interest having sufficient at stake to warrant the heavy expenditures necessary to perfect a satisfactory technological process. This is aside from the incidental damage to the community in destroying what is often the chief source of income of the particular community. This bears certain analogies to the universally condemned 'cutting off one's nose to spite his face,' and also the killing of the 'goose that lays the golden eggs.' If the smelters are not to perfect the technology in this case, who will? And how are they to do it if their revenue is impaired? In fairness, it must be stated that in several cases the courts have refused to issue or enforce injunctions for a period during which experimental work was being conducted. This, we believe, is a sound policy and may well be extended.

In Japan they do even better. Conditions in that country

are not unlike those in our Western states in main essentials. In particular, there is the same condition of undeveloped industry that prevents the direct utilization, in the form of sulphuric acid, of the sulphur in smelter fume. On the other hand, agriculture is highly developed and every acre of cultivable land is used. Damage to crops is a serious matter where nearly fifty million people must be sustained in an area about equal to that of California and with but 12 per cent of the land suitable for cultivation. Establishment of smelters in such a country, necessary as it is, brings up smelter-fume problems in their most acute form. The smelting industry of Japan is still in an early stage so far as industrial organization is concerned. There is no great 'smelting trust' and custom smelting is not general. Practically each large mine has its own smelter, or, rather, each large mining partnership has at least one smelter. The three leading copper mines of the country each supply a separate plant. The Kosaka mine of the Fujita company is situated in the mountainous country of the far northern provinces where little damage is possible. The Osaruzawa mine of the Mitsu-Bishi company is in the same situation. The Ashio mine of the Furukawa company is in a region where the valleys are devoted to rice farming and great care is therefore necessary to neutralize both the smelter fume and the waste water from concentrating mills. For the first the Asano process of treatment with lime-water has been adopted, and, while not entirely successful, it accomplishes such a degree of neutralization as permits the smelter to continue in operation. In the treatment of the waste water from the mills neutralization with lime-water has been combined with sand filtration so effectively as to produce an actual profit from copper otherwise lost.

At the Besshi mine of the Sumitomo company, perhaps, the experience has been most informing of all. This mine is now producing about 600 tons per day of ore containing 30 to 33 per cent of sulphur. The ore is smelted in blast-furnaces, with pot-roasting of the fine material, in an excellent modern plant built in 1904 on Shisaka island, to which the works were removed from the mainland to prevent further damage to agriculture from fume. The island is in the Inland sea ten miles from the nearest important land. Despite this distance, complaints of damage continued after the erection of the new works. Experiments have accordingly been undertaken to determine methods of preventing damage. These experiments have been made by the engineers of the company under the supervision of a commission of technical men, appointed by the Government. This same commission, it may be noted, has full charge of all matters relating to fume damage, and complaints are made to, and adjusted by, it rather than the courts. In other words, technical matters are judged by technical men, rather than left to decision by judge and jury. The commission includes professors of mining, forestry, and agriculture in the Imperial Universities, and the particular committee handling the experimental work includes Mr. Wataru Watanabe, the director of the Engineering College of Tokyo Imperial University, chairman; Mr. Jisaburo Yokobori, professor of metallurgy at the Kyoto Imperial University; and Mr. Yoshitaro Watanabe, professor of metallurgy in the Kyushu Imperial University. Agricultural experiment stations are maintained on the main islands on three sides of the plant and careful observations are being made of the effect of each change as made. One interesting test was as to the effect of dilution resulting from the height of the chimney, which rises 212 feet above the plant. It was found that the percentage of SO_2 in the air on the mainland was not different when the smoke was released at the base of the stack from what it was when released from the top. In other words, any reasonable height of stack was insignificant

which damage was claimed. Attempts were made to neutralize the SO_2 by mixing coal gas with the furnace gases, and the amount was brought down to one per cent. Interesting experiments are now under way, in the direction of clearing the fume by sucking it through a 2-inch layer of filtering media of various sorts. Many of the lines of research undertaken proved unprofitable, others are promising, none have as yet proved entirely successful and at the same time economical. Under conditions obtaining in the United States probably an injunction would be issued and the works closed. Instead, they are running, and good crops are being regularly harvested. In the agricultural experiment stations conducted as a part of the general investigation it was found that damage was done by the fume in only a certain limited portion of the growing season. In the case of rice, the main crop, the injury occurs almost altogether within 20 days of the year, though danger extends through 40 days. Accordingly the crops are watched by experts, and when the danger season arrives, notice is sent to the smelter. The output then is reduced by one-third, and the plant continues to run at the lower capacity for 40 days, or until notice from the experts indicates that the rice is past danger of damage. The remainder of the year the plant runs at full capacity. This appeals to us as a simple and effective method of meeting present difficulties pending perfection of process such as will permit smelters to run profitably at full capacity and without question of damage to agriculture. We commend it to the attention of state and national authorities in the United States.

The British Language

Certain anecdotes are perennial in nature, and the legend on a shop on the Rue Rivoli, Paris, "English spoken and American understood," is often cited. The content of the jest is not all humorous, for to the foreigner the differences in intonation and accent, added to rhetorical divergences, are quite enough to prevent comprehension of the one by a person who has only a limited acquaintance with the other. Americans not infrequently find difficulty in readily following the conversation of a British friend, especially if he drops into what has not altogether inaptly been termed 'English brogue.' An instance is seen in the quotations, given in our Kalgoorlie letter, from a cablegram sent by an Australian mine manager to his London office, "Lode is disturbed by slide. ' * ' (The Horse-Shoe and Ivanhoe lodes are frequently disturbed by slides.)" The natural inference from this is that the outcrop of the vein has been carried away by a landslide, though it is far from obvious how this could happen frequently. But a closer scrutiny shows that this cannot be the case, as the context shows that the reference is not to the outcrop, but to the vein on the 2800-foot level. Presumably the idea which it is desired to convey is that the vein is faulted; a not uncommon phenomenon in the Horse-Shoe and Ivanhoe veins. Similarly, a reference to the "strike of the British colliers" does not mean that vessels have collided, but that coal miners have ceased work. Without multiplying instances, it is evident that American slang has its analogue abroad. Slang has the advantage that it is sometimes picturesque and forcible, while the use of common parts of speech in an obscure or colloquial sense is merely confusing, without any compensating advantage. A few colloquial or slang words introduced into speech or writing often serve to give a distinctive flavor; like the shred of garlic in the salad; but in both cases judgment and discrimination are necessary. The purpose of written speech is to convey information, with the possible exception of in some company reports. Good judgment, therefore, dictates the choice and use of language

The Mining Law—Its Faults and Suggested Changes

By HORACE V. WINCHELL

*The question of national mining laws is of special interest just now in both Canada and the United States. Attention has been widely called to the many defects and general insufficiency of existing statutes, and wherever the matter has been discussed, the need for revision has been admitted. In the United States during the past decade there has been frequent agitation of the subject. Public officials connected with the administration of our land and mining laws have urged legislation along certain lines; the Director of the Geological Survey and the Secretary of the Interior have discussed it in their annual reports; and the matter has engaged the attention of Presidents, Mr. Roosevelt and Mr. Taft discussing it in messages to the Congress. Associations and societies of various descriptions, after due consideration, have passed resolutions demanding this or that measure of relief, and in some cases committees have been appointed for the purpose of making recommendations as to the principles to be followed in new legislation. Thus, a few years ago a committee of prominent mining engineers, among whom were John Hays Hammond and James Douglas, united in a report upon this subject to the Government at Washington; but nothing came of it, and so far as I can learn, the report was never even published. More recently the matter has again been agitated and committees for its consideration have been appointed by the American Mining Congress and the Mining and Metallurgical Society of America.

CANADIAN PROPOSALS FOR CHANGE

The United States might well profit in this matter by the very sensible and systematic method which has been adopted in Canada to facilitate the proper settlement of this most important question. Here, as I am informed, a committee of engineers and attorneys has been selected by the Canadian Mining Institute to draft a bill for a Canada Mines Act, and to present the same for consideration and adoption by the Dominion Parliament. In other words, you Canadians are proceeding in the best way to procure laws framed by experts; and none can doubt that statutes thus prepared are in every way superior to enactments whose subject matter is prepared by theoretical political economists on the one hand or by agitators and professional politicians on the other. I wish therefore at the outset to commend the Canadian Mining Institute for its very wise procedure in this matter and admonish you not to weary in well-doing, nor to be disheartened at slow progress. When you have accomplished what you have set out to do, you will not only have that pleasant sense of satisfaction which succeeds the consciousness of duty worthily performed, but you will have made an investment of time and labor which will return a thousand-fold in actual wealth and prosperity. For that country which is willing to be guided as to the handling and development of its mineral resources by the crystallized policies of its mining engineers is the country whose mining industry will be at once best managed and the most productive of material blessings for all the people.

SYSTEMS OF MINING LAW

The mining laws of a country are those legislative enactments or customs established by precedent which control the acquisition and tenure of mining rights and property, in contradistinction to 'mining regulations' which have to do with the methods and appliances used in operating mines. The principles underlying the mining laws of various countries have been found susceptible of classification into two groups: "(1) The *concession* system under which the state or a private owner of mining property has the right to grant concessions or leases of such mining property to in-

dividuals or corporations at discretion, or under certain general restrictions. (2) The *claim* system, under which any individual, under certain general specified restrictions, generally as to nationality and color, has the right to locate on discovery or otherwise certain limited areas of ground, and under certain conditions to hold, work, and dispose of the same."¹

Under the concession system the right to grant lies with the owner, and it is said that five-sixths of all the mining areas of the world are held under it; under the claim system the right to claim mining ground lies with the locator or discoverer. The latter is the system underlying the laws of Canada and the United States, as well as South Africa and Australia; but there are fundamental differences in these countries as to the nature of the possessory right and the character of title finally obtained.

THE CONCESSION SYSTEM

Originating in the ancient proprietary rights of kings and feudal lords to the minerals in the ground, the concession system still prevails in more or less modified form under all the ancient civilizations of the world. Its chief advantage is in the retention by the state of the right to select and control the operations of its concessionaires, thus assuring proper capitalization and development, good management, economical use of raw material, and the payment of rental or royalty.² To this system there have been objections as follows: (1) that it places unduly large property control in the hands of a few men, and takes from the poor working man the chance of sudden wealth; (2) that by destroying competition in the sale of mines it places in the hands of the holders of large concessions the power of unlimited capitalization and speculation; (3) that it leads to the tying up of large areas of mining ground and thus restricts the employment of labor and the mineral production of the country. To these objections it may be answered that a relatively small number of men will always have control of the money with which to buy and develop mining property, no matter how it be granted; that the Government may easily regulate the capitalization of its lessees; and that a large, strong corporation is usually better prepared to thoroughly prospect its territory than the unaided though far more numerous prospector. If diligent prospecting is required as a condition in the concession, the system of preference rights to explore large areas with the further right to take out leases of limited area would seem to present many practical advantages for new and unexplored countries.

THE CLAIM SYSTEM

The claim system grew out of conditions in early mining days in the United States and Australia. The Argonaut horde who invaded California in 1849 and a few years later rushed to Australia were in many cases allowed to make their own local rules as to size of claim, method of discovery, staking, recording, and obtaining title. In the United States the usages thus established were later sanctioned by Congressional enactment which grew into our present system of mining law, and also served to greater or less extent as a model for Australia and other nations. This system, "however necessary in the peculiar circumstances of its inception, should have been altered as soon as changing circumstances permitted," but instead it has been patched and interpreted by judicial decision until the United States has today the most wretchedly inadequate and antiquated law with which a great country is anywhere afflicted. Instead of fostering the mining industry the law as it stands today and as interpreted by the judicial and

*Presented to the Canadian Mining Institute at the Toronto meeting, March 6.

¹'Mining Law of the British Empire,' C. J. Alford, London, 1906, p. 1.

²Alford, *loc. cit.*, p. 2.

executive branches of the Government creates confusion, entails unnecessary expense, causes waste, and retards development.

COMMON PRINCIPLES

Two fundamental principles are common to the mining laws of all countries: (1) The right of the mine-holder to a perfectly secure and indefeasible title to his property so long as he fulfills certain specified conditions entirely within his own control, and (2) the right of the state or other landlord to certain rents, royalties, or taxes on the property or its output, and to the reasonably constant operation of the mine.

In the power of the Government to fix the rate of royalty or taxes lies also the ability to promote or to discourage prospecting and mining. If the chief aim of the Government is the development of national resources and the increase of general prosperity and business, its policy for the disposition and holding of its mineral lands will be most liberal. If there is a desire to enrich the public treasury directly by means of revenues from taxes upon mines, the result may be a rapid decline of the mining business, and a shifting of the population to more favored communities. It is frequently stated, and truly, as I believe, that the principal factor in the growth and development of the United States and Canada has been the liberality of their policy for the distribution of their public domain. Freely, or at a nominal consideration, homesteads and mines have been offered to all who chose to come and settle, to develop and use. If during the past fifty or seventy-five years the policy of conservation as now advocated by its most ardent proponents had been expressed in our statutes North America would be for the most part as little developed as Alaska. There would be a line of settlements along the Atlantic and a few fishing hamlets on the Pacific. The interior of the country would still be to a very large extent bottled up and conserved; and the country would perhaps be still importing the bulk of its copper and iron as it is its supply of tin, platinum, potash, and nitre.

MINERAL WEALTH OF THE UNITED STATES

To speak to an audience of mining men of the importance of a liberal mining law is like carrying silver to Cobalt or copper to Butte, but since these remarks may find a wider audience, a few words upon the extent of our mining industry may not be out of place. First, with reference to the United States. The annual products of the mines of the United States now exceed \$2,000,000,000 in value. They contribute 65% of the freight traffic of the country. The industry employs over a million men at the mines and twice that number in handling, transporting, and manufacturing the products.³ The total value of our metallic products during 1907 was \$900,000,000; of mineral fuels, \$788,000,000; and of non-metallic mineral products, other than fuels, more than \$378,000,000. During the year we imported mineral products to the value of \$255,000,000 and exported mineral products to the value of \$340,000,000. From the beginning of coal mining in this country in 1814 to the close of 1907, there were mined nearly seven billion (6,865,000,000) tons. Adding to this the one-half additional supposed to have been wasted in mining, gives a total of more than ten billion tons taken from the supplies originally available. The amount of easily accessible and available coal in the United States, exclusive of Alaska, is estimated as 1,400,000,000,000, while the total, including Alaskan reserves of 150,000,000,000 tons and the coal not easily accessible, is perhaps double this amount, and the country is as yet but partly explored. It may be remarked in passing that since the United States is now mining about 500,000,000 tons of coal annually we would appear to have a coal supply sufficient for about 6000 years at the present rate of consumption, even without borrowing or buying from the enormous coal bins of Canada. Can anyone doubt that the provisions of the laws governing the disposition of the fifty million acres of coal land still remaining in the hands of the

Government is a matter of importance to a nation with an annual coal consumption of five tons per capita?

AREA OF PUBLIC LANDS

Figures are wanting as to the quantity and value of other mineral products estimated to remain within the unappropriated public domain. The land area of the United States, excluding Alaska and the insular possessions, is about 3,000,000 square miles, or 1,920,000,000 acres. Of this area over half is arable, and a little less than half is occupied as farm land. About two-thirds of the land has passed into private holdings. Of the original acreage there remained on July 1, 1908, 387,000,000 acres, or about one-fifth open to entry. Nearly all of this is arid or otherwise unsuitable for settlement by families. There are also about 235,000,000 acres in national forests, national parks, and other lands reserved for public use. Of the entire area of 1,920,000,000 acres there remain unalienated about 622,000,000 acres or nearly one-third within which valuable minerals may still be discovered. Is it not a matter of vast importance to provide most carefully for the exploration, disposition, and development of this vast empire? In what direction can the fostering care of government be more profitably and properly extended? And when Alaska, with its undeveloped area of about 360,000,000 acres, and the island possessions with 90,000,000 more acres, are taken into account, is it not clearly one of the largest questions before the public today?

CANADIAN CONDITIONS

In Canada the percentage of unappropriated public domain is larger than in the older country lying along its southern border, and there is yet ample time to avoid the mistakes of omission and commission of the United States. With a total area of 2,118,814,000 acres, you have still in the hands of your Provincial and Dominion Governments the larger part of your acreage. Your annual production of minerals is valued at about one hundred million dollars. At its present rate of increase it may easily amount to five hundred million dollars by 1950. Can your engineers find any more truly national work than to aid in the framing and adoption of the best possible laws for the protection and encouragement of the mining industry? Is it not apparent that there is a very close connection between mining laws and that conservation idea so dear to the imagination of the majority of our people today? If the true aim of conservation be "maximum use with minimum waste," is it not evident that to be consistent with this theory, mining laws must be liberal as to opportunity and inducement for the individual or corporation, and at the same time as scrupulous and exact in supervision and scientific regulation as the conditions of industry and the laws of political economy will permit? If the terms and conditions for acquiring mining property be so difficult as to materially restrict the number of prospectors or development companies there will be far less than "maximum use"; and if no right of supervisory control is retained by the Government there will seldom be "minimum waste." The best code of mining laws will inevitably aid in the development of natural mineral resources, and at the same time have a tendency toward the right species of conservation, as contradistinguished from that variety of it which seems to aim at disuse, stagnation, and paralysis.

FAILURE OF AMERICAN MINING LAW

In many particulars the present mining law of the United States is admittedly a failure, and in other respects it has both its critics and defenders. I propose to mention briefly some of its defects, and some possible amendments, not because there seems to be any danger that our worst faults will be copied by others, but in the way of general illumination of a question which is not always clearly understood even by our own people.

Briefly stated, the United States mining law, known as the Act of 1872, provides for location by discovery; possession perpetuated by annual assessment work; and title in fee simple to the surface and minerals obtained after the expend-

³Report of the National Conservation Commission, Vol. I, p. 95, Washington, 1909.

iture of a certain amount of money by the payment of \$5 per acre, and the observance of certain formalities as to survey, etc. The metal-mining laws do not apply to all of the states. They are made applicable to the Western states and territories with the exception of Michigan, Wisconsin, Minnesota, Missouri, Kansas, and Texas. Mining locations are not recognized in the states east of the Mississippi river, nor is there in any state legal authority permitting one man to prospect or mine beneath the surface of ground owned by another without consent of the latter. To this statement there is one important exception, and that lies in what is called the 'apex law' under which the owner of the outcrop of a vein in mining claims has the right to follow and mine the vein on its downward course beneath the surface of a claim owned by another. This law has proved more productive of expensive litigation than of economical mining, and in many of the more recently established and more progressive mining districts has been made inoperative either by common agreement or by compromise between adjoining owners.⁴ Placer mines are likewise located by discovery and held by annual work and acquired by purchase in fee-simple forever. Known veins within placer locations must be declared and paid for separately or else they are excepted from the placer patent and can be located by others in 'lode claims.' All veins on placer ground not known to exist at the time of application for patent belong to the grantee, but without extra-lateral or apex rights. If an applicant for a placer patent can be shown to have had knowledge of a valuable lode within his lines prior to the making of his patent application, his title as to that vein may be canceled for fraud at any time upon application of a contesting locator. There is no limit to the time for such contests and they are still being brought in some cases twenty years after placer patent. The law is very defective on this point; for it frequently happens that veins discovered today have a value by reason of improved transportation facilities or metallurgical processes, although these same veins were of no value whatever when the placer claim was located and patented. The owner of such a claim is sometimes put to the expense and annoyance of defending such contests repeatedly, since there is no limit to the number of contestants. The law should be amended so as to make it impossible to attack a placer patent on such charges after a reasonable term of years. Another absurd feature of the placer act is that providing for the location of oil, gas, iron ore, and other deposits in the same manner as auriferous gravel. Coal lands are sold by the Government upon an appraised valuation, and the amount of land that may be legally acquired is limited for an individual to 160 acres and for an association to 640 acres. Tracts of such limited area do not often justify the installation of the most efficient equipment, and economical operation is therefore impossible under the terms of the very law which was expressly designed to promote economy and prevent monopoly.

ABSENCE OF LEASING

Under the present United States law there is no general system of separation of surface from mineral rights, no leasing of mines from the Government, no payment of rental or royalty, and no Federal supervision or control after location and patent. Taxes are paid to the state and county, and mining regulation is attempted by many states. Unfortunately there is no uniformity of principle and practice as to these matters, nor any stability, nor assurance of permanence in any state either as to methods of operation required or basis of taxation.

Although it has been successful elsewhere and has much to recommend it, the Government leasing system has never met with much favor in the United States. There is not at present strong opposition to grants in perpetuity by the Government, although the leasing system has been recommended by some organizations and public officials. There is a hesitancy to create more bureaus; for bureaucratic ad-

ministration is not popular with those who have tried to transact business with many of them.

REQUIREMENT OF DISCOVERY

Aside from the generally condemned apex law, there are two or three features of our present system which should be speedily remedied. The first is that provision of the law requiring a discovery of valuable mineral before location. There is really no sense in such a requirement. What seems valuable to one man is often worthless to another; and what is of no value today may be worth a million in a year or two. Moreover, it sometimes requires a year's work and a shaft several hundred feet deep before the actual discovery of ore, even though the surface indications give ample promise of its existence below. Every mining engineer and geologist knows that many ore deposits have no value whatever immediately upon the surface of the ground. Why not allow a prospector to stake out his mining claim wherever he chooses on the public domain, and hold it so long as he performs the required amount of development work?

LIMIT THE NUMBER OF LOCATIONS

Another defect in our present law is that permitting a prospector to locate an indefinite number of mining claims and to hold them without doing his assessment work. Many promising districts are kept from becoming hives of industry and producers of mineral wealth by the tying up of their territory in this way. The prospector should be restricted in the number of his locations, and real development work should be exacted.

RIGHT OF APPEAL

The last important defect in the United States and Alaskan mining and land law to which I wish to call attention is the lack of any provision for appeal to the courts from the decisions of administrative officers. It is contrary to the general spirit of our institutions and an anomaly in constitutional government to take away from any citizen property rights to which he considers himself justly entitled under the law, by the mere fiat of an appointed government official who is here today and gone tomorrow. To place in the hands of such officials the final dicta in matters involving property valued at hundreds of thousands of dollars, and to provide no method of appeal to any duly constituted non-political judicial tribunal is not only to subject the said officials to great and unnecessary tests of moral courage and fidelity, but to require in them the qualifications of superior judges and experience in the interpretation of the law which many of them cannot be expected to possess. Serious injustice may be done without any remedy at law to the defeated applicant. In the interests of justice, provision should be made for appeals in important cases, and perhaps in all cases, from decisions of the Commissioner of the General Land Office or the Secretary of the Interior to some court of competent standing and jurisdiction, whose decisions could and would be accepted by the public and the interested parties as justified by the law and evidence. I am gratified to notice that this point has been carefully covered in the recommendations of the Canadian committee on this subject.

COMPARISON OF ENGLISH AND AMERICAN SYSTEMS

A comparison of the mining laws of the United States with those of other English speaking countries will disclose a fundamental difference in the underlying theory of the proprietorship of minerals, and hence in the attitude of the courts upon the subject as reflected in their decisions. Recent publications of a report upon the 'Mining Laws of Australia and New Zealand,'⁵ has caused considerable discussion because of the fact that its recommendations have been to a certain extent adopted by other government officials in their annual reports and public addresses. This report apparently assumes a similarity between British laws and those of the United States in certain respects where actually a wide difference exists.

⁴Thirty-Second Annual Report, Director U. S. Geol. Surv., p. 15, Washington, 1911.

⁵Bull. 505, U. S. Geol. Surv., by A. C. Veatch, with a preface by Walter L. Fisher, Washington, 1911.

ABSENCE OF REGALIAN RIGHT

"Neither regalian right, nor anything similar, has ever existed in or been asserted by the United States. While it has sovereign authority, and the power to enact such statutes as Congress in its wisdom sees fit, within the limits of the Constitution, its right is dependent upon and controlled entirely by statute."⁶ Furthermore: "A distinction exists, and should be observed between ultimate ownership and right to govern on the one hand, and the exercise of regalian right, after possession and title is parted with, on the other. The former exists in the United States, the latter does not. The ownership, as well as the manner of exercising control, of mineral lands is regulated in the United States by statute."⁷

"The fundamental principles of the common law of England were to a certain extent ingrafted into our legal system when we separated from the mother country and were and still are the rule of action in the absence of legislation. As a general rule, under the common law minerals were the property of the owner of the land, the property in the surface carrying with it the ownership of everything beneath it.⁸ Wherefore the ownership of the surface was the best *prima facie* title to the ownership also of the mines.⁹ This *prima facie* ownership continued until rebutted by showing either: (1) that the land contained 'royal mines'; or (2) that it was subject to some particular custom that defeated the *prima facie* ownership, as in the case of the tin mines of Cornwall and Devon and the lead mines of Derbyshire; or (3) that the ownership of the mines and minerals had become in fact, from divers causes several and distinct from the ownership of the soil and surface."¹⁰

By the term 'royal mines' was meant mines of gold and silver. These belonged exclusively to the Crown, by prerogative, although in lands of subjects. In this respect the rule was the same as under civil law. It was at one time contended that mines or mineral deposits containing the baser metals in combination with either gold or silver were royal mines. This contention, however, was set at rest by statutes enacted during the reign of William and Mary,¹¹ wherein it was declared that no mine should be deemed royal by reason of its containing tin, copper, iron, or lead in association with gold or silver. Thus, those mines only came to be classed as royal in which were found the precious metals in the pure state. Briefly stated, the regalian right to mines, as recognized in England, was confined to those of the precious metals, gold and silver. The base substances belonged to the owner of the soil, except in certain localities where immemorial custom had modified the rule.¹²

At the present time "England has no general mining laws. Legal questions governing the ownership of mines and minerals have been determined on the general principles of the common law."¹³

As distinguished from the common law the theory of the civil law is thus clearly stated by H. W. Halleek:

"All continental publicists who have written upon the subject lay down the fundamental rule, that mines, from their very nature, are not a dependence of the ownership of the soil; that they ought not to become private property in the same sense as the soil is private property; but that they should be held and worked with the understanding that they are by nature public and that they are to be used and regulated in such a way as to conduce most to the general interest of society."¹⁴

C. H. Lindley has presented concisely the theory of our leading mining lawyers as to governmental control after patent, as follows:¹⁵

⁶Snyder on Mines, Vol. I, p. 15.

⁷Lindley on Mines, Vol. I, p. 4, First Edition.

¹⁴Introduction to De Fooz on the Law of Mines, p. x; Lindley on Mines, 1st Ed., Vol. I, p. 14.

¹⁵Lindley, *loc. cit.*, p. 29.

"The Government of the United States does not concern itself with mining lands or the mining industry after it parts with the title. This title vests in the patentee absolutely to the extent of the property granted. No royalties are reserved; nor is any governmental supervision (except perhaps in the isolated case of hydraulic mines in California) attempted. Upon the issuance of the deed of the Government the mineral land becomes private property, subject to the same rules as other property in the state with reference to the transfer, devolution by descent, and all other incidents of private ownership prescribed by the laws of the state. Briefly stated, property in mines, once vested absolutely in the individual, becomes subject to the same rules of law as other real property within the state."

DID THE UNITED STATES WAIVE ITS RIGHT?

But lately we are told that the United States "has never waived its right to the precious metals,"¹⁶ and that "in all states where the Federal Government has never owned the land, and there are 19 such states, the ownership of the precious metals lies with the state government," and "that in states where the ownership of the land has been vested in the Federal Government the ownership of the precious metals in like manner, lies with the nation, and that as against the Government no person has a right to gold and silver in any lands in the United States unless this right has been specifically granted to him in the deed of conveyance."¹⁷

Here is a most radical difference of theory. Mr. Veatch would have the Government resume dominion and control of gold and silver and by implication of other metals beneath the surface of all lands except those in which minerals were specifically conveyed. He thinks the Government has the right to grant prospecting permits beneath private property and the power to collect royalties on minerals produced as a result of such explorations. In other words he insists upon it that the United States is in possession of a regalian right, but does not know it or has forgotten it. He would have the people wake up and seize what is theirs from all mine operators who are thus wrongfully removing from the ground valuable minerals never specifically granted to them by the Government. It can readily be seen that it is a matter of no small moment to ascertain whether such a thing is possible. Here is proposed mining law revision with a vengeance. I have not at hand the figures to show the relative proportion of lands patented as mineral lands and in all other classes; but have no doubt that the lands granted under the homestead, pre-emption, desert land act, private entry, townsite, timber and stone, railroad grants, and all other laws exceed in the aggregate the lands under the mining laws four to one. Now, if the minerals under three-fourths of the privately owned land west of the Mississippi, and practically all the lands east of it, really belong to the Government, it is high time for the Government to assert its right and to exercise some sort of control over its vast possessions. This is either a nebulous and iridescent dream or a very important discovery. If the former the bubbles should be punctured, and the mist dispelled, before arousing too many false hopes; if the latter the work of mining law revision at once assumes paramount importance. Fortunately, we have some illuminating opinions of the United States Supreme Court, as a guide and cloud dispeller.

OPINIONS OF THE SUPREME COURT

In the case of *Deffeback v. Hawke*, 115 U. S., p. 400, Mr. Justice Field, after reviewing at length the various acts of Congress relating to the public lands of the United States, concludes as follows:

It is plain, from this brief statement of the legislation of Congress, that no title from the United States to land known at the time of sale to be valuable for its minerals of gold, silver, cinnabar, or copper, can be obtained under the pre-emption or homestead laws or the townsite laws, or in any other way than as prescribed by the laws specially authorizing the sale of such lands, except in the states of Michigan,

¹⁶Bull. 505, U. S. Geol. Surv., p. 116.

¹⁷Bull. 505, U. S. Geol. Surv., p. 101.

Wisconsin, Minnesota, Missouri, Kansas. We say 'land known' at the time to be valuable for its minerals,' as there are vast tracts of public land in which minerals of various kinds are found, but not in such quantity as to justify expenditures in the effort to extract them. It is not to such lands that the term 'mineral' in the sense of the statute is applicable. In the first section of the act of 1866 no designation is given the character of mineral lands which are free and open to exploration. But in the act of 1872, which repealed that section and re-enacted one of broader import, it is 'valuable mineral deposits' which are declared to be free and open to exploration and purchase. The same term is carried into the Revised Statutes. It is there enacted that 'lands valuable for minerals' shall be reserved from the sale except as otherwise expressly directed, and that 'valuable mineral deposits' in lands belonging to the United States shall be free and open to exploration and purchase. We may also say lands known at the time of their sale to be thus valuable, in order to avoid any possible conclusion against the validity of title which may be issued for other kinds of land, in which years afterward, rich deposits of mineral may be discovered. It is quite possible that lands settled upon as suitable only for agricultural purposes, entered by the settler and patented by the Government under the re-emption laws, may be found, years after patent has been issued, to contain valuable minerals. Indeed this has often happened. We, therefore, use the term known to be valuable at the time of sale, to prevent any doubt being cast upon titles to lands afterward found to be different in their mineral character from what was supposed when the entry of them was made and the patent issued.

And in the case of the Colorado Coal Co. v. the United States, 123, U. S., p. 528, Mr. Justice Matthews uses the following language:

A change in the conditions occurring subsequently to the sale, whereby new discoveries are made or by means whereof it may be profitable to work the veins as mines, cannot affect the title as it passed at the time of the sale. The question must be determined according to the facts in existence at the time of the sale. If upon the premises at the time there were not actual 'known mines' capable of being profitably worked for their profit, so as to make the land more valuable for mining than for agriculture, a title to them acquired under the pre-emption act cannot be successfully assailed.

Since these are the opinions of the highest court in our land it is probable that although the advocates of radical revision of our mining law may be able to change the form of its superstructure they will hardly be able to mine deep enough to disrupt its solid rock foundations. It will continue to present fundamental differences from the mining law of Canada on the north, and from that of Mexico on the south, but rights already granted will not easily be set aside.

GENERAL CONCLUSIONS

Summarizing these somewhat disjointed remarks, it appears in general that:

1. The development and prosperity of all countries is vitally affected by the provisions of their laws relating to mines.

2. Greater inducements and more liberal rewards should be offered in unsettled countries than in districts of denser population.

3. Continuous development work should be required and rigidly enforced, but

4. No narrow limit should be placed on the amount of property held by an individual or corporation so long as the aggregate amount of work equals the product of the net units of area held multiplied by the amount of development required for each unit area.

5. In case of any contest either between rival claimants or between a locator and the Government full privilege should be given of appeal to the courts as in other matters wherein the title to property is involved.

In addition to the above, and with particular reference to the United States, taking into account the system of mining law there already established by long years of precedent and custom, the following recommendations are tentatively presented:¹⁸

a. The apex law should be abolished.

¹⁸It should be clearly understood that for these suggestions the writer is alone responsible. They do not in any sense pretend to reflect the views of the Mining and Metallurgical Society of America, or its Committee on Mining Law.

b. Mining claims should be locatable regardless of a 'discovery' and held only so long as the specified development work is performed in good faith.

c. Placer locations should be limited to deposits of loose materials above solid bedrock.

d. A statute of limitations should establish a reasonable term of years beyond which placer patents shall be immune from attack on the ground of misrepresentation in the patent application.

e. Special statutes should be enacted providing for the location and working of oil, phosphates, rare earths, haloids, and other mineral substances not specifically mentioned in the present laws.

f. Existing titles should be fully recognized and confirmed and no effort should be made to create retroactive legislation.

I have purposely avoided any discussion of the relative advantages or disadvantages of permanent alienation of title as opposed to the government leasing system. For Canada, I am confident the latter system is to be preferred, and am pleased to find myself upon this point in accord with the majority of Canadian mining men.

Hydraulic Equivalents

The U. S. Geological Survey prints in many of its Water-Supply Papers a list of convenient equivalents for use in hydraulic computations. The following form a portion of the list:

1 second-foot equals 40 California miner's inches (law of March 23, 1901).

1 second-foot equals 38.4 Colorado miner's inches.

1 second-foot equals 40 Arizona miner's inches.

1 second-foot equals 7.48 United States gallons per second; equals 448.8 gallons per minute; equals 646,272 gallons for one day.

1 second-foot equals about 1 acre-inch per hour.

1 second-foot for one day covers 1 square mile 0.03719 inch deep.

1 second-foot for one day equals 1.983 acre-feet.

1 second-foot for one 28-day month equals 55.54 acre-feet.

1 second-foot for one 29-day month equals 57.52 acre-feet.

1 second-foot for one 30-day month equals 59.50 acre-feet.

1 second-foot for one 31-day month equals 61.49 acre-feet.

100 California miner's inches equals 18.7 United States gallons per second.

100 California miner's inches for one day equals 4.96 acre-feet.

100 Colorado miner's inches equals 2.60 second-feet.

100 Colorado miner's inches equals 19.5 United States gallons per second.

100 Colorado miner's inches for one day equals 5.17 acre-feet.

1,000,000 United States gallons per day equals 1.55 second-feet.

1,000,000 United States gallons equals 3.07 acre-feet.

1,000,000 cubic feet equals 22.95 acre-feet.

1 acre-foot equals 325,850 gallons.

1 cubic foot equals 7.48 gallons.

1 cubic foot of water weighs 62.5 pounds.

1 horse-power equals 1 second-foot falling 8.80 feet.

To calculate water-power quickly:

Sec.-ft. \times fall in feet

11 = net horse-power on water-wheel realizing 80% of theoretical power.

THE Zaruma mining district of Ecuador has long been considered one of the richest and most promising mineral zones of the Republic, but up to the present time the cost of transportation and the difficulties attending a profitable exploitation of the mineral deposits of that region have greatly retarded its development. The railway from Machala to Loja, a concession for the construction of which has been granted, will traverse this rich section of Ecuador, and should greatly stimulate not only the development of the mining industry but of agriculture and stock raising as well.

The International Smelter, Utah

The Utah smelting plant of the International Smelting & Refining Co. is 4 miles east of Tooele, in Tooele county, Utah. Construction of the plant, which was designed by C. H. Repath, was started early in 1909, and the copper-smelting equipment was blown in July 1910. Recently two lead furnaces and a bag-house have been added to the plant and will be blown in early this year. These do not appear in the accompanying illustration, which shows only the copper-smelting equipment. The smelter is on the west side of the Oquirrh range of mountains, on the eastern slopes of which are the mining districts of Bingham and Tintic. The Utah Metal Mining Co. is now engaged in driving a tunnel, over 11,000 ft. long, from a point in Pine canyon near the smelter, to a point on Carr Fork, on the Bingham side of the range. This tunnel is 8 by 9 ft., double tracked, and has a grade of $\frac{1}{2}\%$. Besides cutting orebodies in depth, it has developed a considerable flow of water. Pending the completion of the tunnel an aerial tramway, 4 miles long, is employed to transport ore across the range; one end of the terminal is

is now tapped into a ladle, so that some idea may be obtained of the quantity being used. The converters are ordinary shells which have been supplied with a basic lining, and are only operated on day shift, being kept hot over night by filling them with cinders from the reverberatory furnaces. In this way it is possible to make a slag containing 33% SiO_2 ; the silica is supplied in the form of silicious lump ore, two 'boats' of ore usually sufficing for an 8-ton charge of matte. The plant is producing about a million pounds of blister per month. The converter-building is marked *H* in the illustration. The main stack is at *L*. All parts of the plant are served by a series of interconnecting tracks; those at *b* and *d* are the charge tracks from the crushed-ore bins; *c* is the track to the reverberatory furnaces; and *e* is the track to the converter house; and the tracks to the receiving bins are seen at *f*.

Near the point from which the photograph is taken is the lead-smelting plant of this company. This consists of Dwight-Lloyd roasters, two 50 by 180-in. blast-furnaces, and a bag-house; this equipment is just in process of being put into use. For some time ores have been purchased and placed on the stock piles at the smelter, and contracts have been made with a number of lead mines, among them

COPPER SMELTING PLANT, INTERNATIONAL S. & R. CO.

seen at *A* in the illustration. From this point the ore goes to the main receiving bins, *B*, in standard railway cars, as also do the ores from other districts. The shed at *B* covers the bin-spouts, whence the ore is drawn off into charging cars. At *D* is seen the sampling mill, and *C* is the building in which silicious ores for lining are crushed. The crushed and sampled ore then goes to the bins at *E*. The sulphide ore, after crushing, is drawn out upon a series of automatically weighing belt-conveyors, which convey it to the McDougall roasters in the building at *K*. There are 32 of these roasters, but only 15 are in use, as the ore tonnage received while the tunnel is under construction is somewhat restricted. A certain amount of silicious ore is added upon the fifth hearth of the roasters, thus keeping the temperature at the proper elevation and serving to heat the ore. The dust-chamber for the roaster gases is seen at *J*. The sulphides are roasted so that the smelting charges contain about 7% S; this corresponds to a matte-fall of 15 to 18 tons per furnace-day. The furnaces, contained in the building seen at *G*, are of the Anaconda type and smelt about 200 tons each per day, with a fuel consumption of 52 tons of coal per day. The waste-heat boilers furnish power enough for the generation of electricity to supply the plant and the Highland Boy mine. The power-house is seen at *F*. The reverberatory-furnace slag, which is 40 to 42% SiO_2 , is tapped off directly at the back of the furnace, and the matte, which runs 20 to 30% Cu, was at first tapped directly into the converters, but

the Daly-Judge at Park City and mines in the Coeur d'Alene. The lead bullion will be shipped East for refining. An interesting feature of the bag-house construction is the method of removing the collected fume from the bags. This will be done by reversing the direction of the current for a short time in a 'bay' of bags by reversing the direction of rotation of the fan. The accumulated fume is thus drawn into the chamber beneath, where it can be collected and drawn off into cars. This method was devised at the Midvale plant of the United States S. R. & M. Company.

The copper-smelting plant, which has a capacity of 1500 tons per day, is at present handling about 800 tons per day. This is due to a shortage of ore-supply, as the mines have been unable to deliver the expected tonnage. When the long tunnel of the Utah Metal Mining Co. is completed it is hoped that a more ample supply will be available. The heading from the Tooele side had advanced 7000 ft. on February 1, while the Bingham heading had only reached a length of 600 ft., leaving approximately 4000 ft. to be done, as the total length of the tunnel is a little over 11,000 ft. At the present rate of advance the work should be completed about September 1.

The possibility of trouble from damage done by fume has been discounted by the securing of easements upon a majority of the farms lying within four miles of the smelter. The company is thus free from danger of being closed by injunction, but is still subject to suits, though no damage has been done as yet.

Mechanical Features of the California Gold-Dredge—III

By ROBERT E. CRANSTON

***WIRE ROPE.**—Wire rope is used on the dredges for hoisting the digging and stack ladders, spuds, for all the swinging-lines, and for guying the gantries. On account of the small diameter of sheaves, the necessity for the ropes being under water part of the time, and the general hard service they get, their life is short as compared with ropes used for most other purposes. Some dredge constructors use the regular open and closed sockets for their guy-rope ends, and others think this practice is dangerous and use clips. I have never had any trouble with standard rope-sockets if properly attached to the rope end. This may be done by first spreading the wire strands, treating them with dilute hydrochloric acid, inserting in the socket with the strands spread broom fashion, and then filling with melted zinc. The ends of the wires should not be turned over, but left straight. If turned over some are likely to get more strain than others, and to break and cause trouble. Different makes and types of wire rope are used. My experience points to standard 6/19 plow-steel hoisting rope for ladder, spud, and side lines, and 6/7 crucible cast-steel standing rope for the guys. Hot Stockholm tar makes a good dressing, also many of the rope greases to be had on the market. Whatever dressing is employed, it should be used freely.

SHEAVES.—The sheaves used for the various purposes are made of cast steel in preference to cast iron. They are bushed with bronze or cast iron and their hubs made as long as possible. When long hubs cannot well be used, as in multiple blocks, the pins should be made of large diameter, so that the pressure will not be too great on each unit of resisting surface.

PUMPS.—Three centrifugal pumps are ordinarily used on a gold-dredge. The high-pressure pump should be designed to have a working head of at least 60 ft.; more is better if the gravel is at all hard to wash. This pump furnishes the water for the spray pipes or jets in the screens and is direct-connected to its motor. The low-pressure pump is likewise driven by a direct-connected motor and should have a head of 20 to 30 ft. This water is piped to the tables where needed, depending on the nature of the gravel and the arrangement of the gold-saving tables. The priming or fire pump is usually a two-step pump with a working head of 100 ft. or more. This pump is used in case of fire, for washing down decks, in cleaning up, for pumping out the bilge, and for priming the larger pumps. All pumps should be fitted with both foot and check valves. By-pass piping, equipped with the requisite valves, should be put in to be used for priming. The foot-valves are provided with a grating, and the suction should be still further protected by a wire-netting box attached to the side of the dredge. If this box be made of ample dimensions, say 8 by 15 ft., a $\frac{3}{8}$ -in. mesh will work well. If a smaller box be used, $\frac{1}{2}$ or $\frac{5}{8}$ -in. screen will have to be used, otherwise it is liable to become stopped up.

MOTORS.—Three-phase induction motors are used on all standard California dredges, variable-speed for the digging and winch motors and constant-speed for the other pieces of machinery. Lately a form of variable-speed motor has been used for the stacker and screen drive, which gives a better starting torque for getting these parts under way and is particularly useful when it is necessary to start under full or overload. Any of the standard types of motor give most excellent results if the proper sizes are provided.

TRANSFORMERS.—It is customary to bring current to the dredge at 2200 or 4400 volts, then transform down on the dredge with three oil-cooled transformers to 440 volts. Many of the later boats are using 2200-v. motors, thus avoiding

the use of transformers altogether. Besides the three main transformers, another small one reduces the current to 110 v. for lighting purposes. All of the transformers are mounted in steel or asbestos-lined compartments opening to the outside of the dredge. They have pipe connections which allow the oil to be drained off and conveyed overboard to a point some distance from the transformers. These precautions are necessary in order to secure the best insurance rates and are to be recommended as a safeguard against fire. Another precaution which might prove useful is to provide the transformer housings with plate-steel doors hung from the top with an automatic latch at the bottom and so constructed as to be readily dropped and latched in case of fire.

WIRING.—The electric current is brought on board the dredge by a three-conductor armored cable on floats at a point near the stern, this part of the hull having the least movement. An oil switch is placed near this point and is often so arranged that it may be instantly thrown out from the pilot-house. From this switch the current is conveyed to the transformers in case low-voltage motors are used, and from there the secondary is distributed to the different switchboards. The latest boats use conduits and condulets for all the wiring. If open wiring is used, the conductors should not be stretched too tightly, and they should all be stranded. The single wires are likely to break under the severe vibration of digging and the movement of the hull and superstructure. I recommend stranded conductors, even with the conduit wiring. Wiring connections for the motors situated on the lower deck can be made through the hold. For the other motors the best method must be determined according to the conditions.

SPUDS.—The early California dredges used a head-line to dig on, and even after the spud system was introduced it was a mooted question which was the better. The standard California type dredge uses the spud system exclusively, the head-line being abandoned except in a few cases where the nature of the gravel or other conditions are unusual. At first, wooden spuds were used, then one wooden and one steel, the wooden spud being used to step up with and the steel one to dig on. Now both spuds are often made of steel. This plan is by far the best, since if one breaks, the other may be used to dig on, using the head-line to step up with. If only one steel spud is provided and a break occurs, the dredge must be shut down at once and the broken spud taken out, repaired, and put in again before any digging can be done. Several forms of spud are used, and their make-up can best be understood by referring to the figure, which shows views and cross-sections of an unusual design. An extra cover plate riveted to the tension side of that portion of the spud having the greatest strain adds strength with comparatively little increased weight. The lower ends of the spuds are protected by cast-steel points, which extend far enough into the structural part to give ample riveting area. The later designs are made longer than the older ones. At the bottom they are acorn-shaped and change gradually from a circular to a rectangular cross-section at the point where they enter the structural portion of the spud, and they often extend 8 or 10 ft. below this point. Heavy ear springs are often used in the spud frames to reduce the shocks of digging, and those using them think that they lessen the danger of breaking very much. This is doubtless true, but I am of the opinion that it also reduces the digging capacity of the dredge and that the best remedy for broken spuds is to build them stronger.

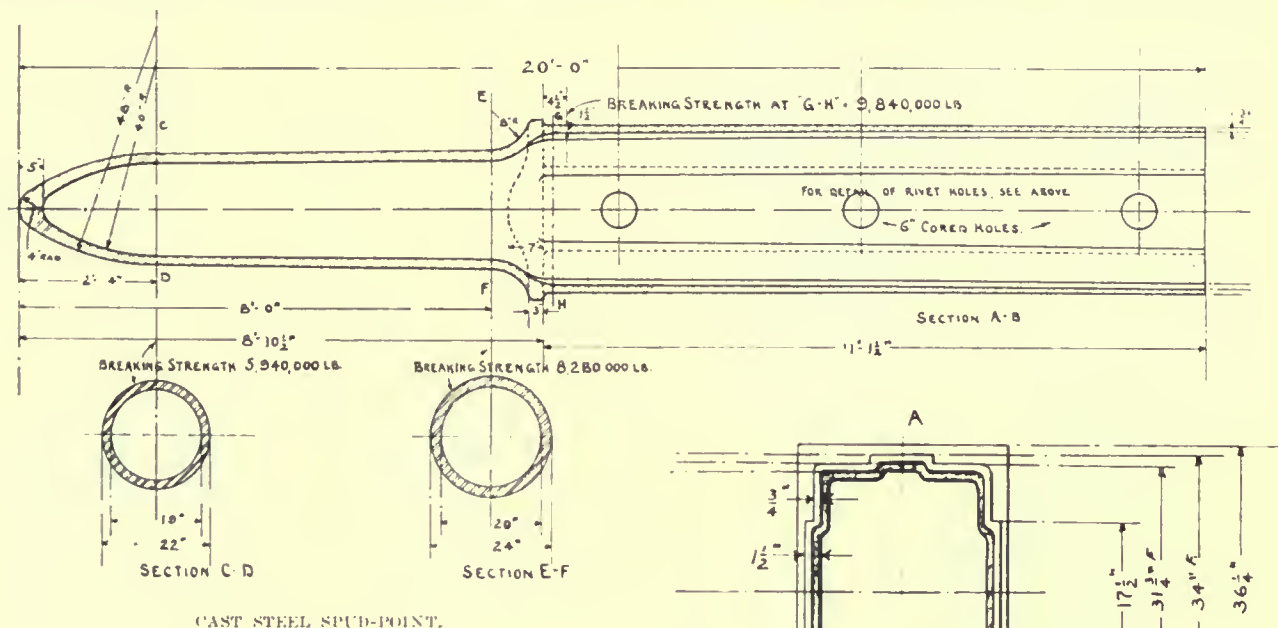

CRANES AND REPAIR DEVICES.—The modern dredges are provided with traveling or boom cranes covering the heavy machinery, so that repairs and replacements may be made expeditiously and without calling in more men than the

*Abstract from the *Journal* of the American Society of Mechanical Engineers. Continued from *Mining and Scientific Press*, page 338.

regular dredge crew. A thwart-ship I-beam with traveler, or a swinging boom covering the forward portion of the dredge and bucket line, is used for changing buckets. Brackets are riveted to the ladder, into which chains are hooked to hold the bucket line after parting. It is well to have an I-beam or at least an eye or hook well secured above the ladder hoist, main winch, pumps, transformers, and screen. Over the bucket line a thwart-ship traveling crane is most useful. It should be of sufficient capacity to lift the upper tumbler, shaft, and gears, and should extend far enough so that these parts may be lowered over the side of the dredge. If a hatchway is provided through the upper deck on each side of the bucket drive, this crane may also prove useful for handling parts on the lower deck.

HULL.—The hull is built of Douglas fir and is proportioned to accommodate properly the machinery which it supports. Before designing the hull, the general dimensions and

The bow is made narrower than the rest of the barge, the frames being shortened and the side planking steamed and bent around them. How much this portion of the hull should be narrowed down will depend on the width of the cut it is desired to make, together with the distance the digging ladder projects beyond the bow. Using one spud as a centre and drawing the outline of the hull, digging ladder, and cut to scale, will graphically illustrate how much to bring in the bows so that the dredge may dig its way along any desired width of cut. This is a general description of the most common type of hull construction. I have been using what I consider a somewhat stronger construction, but one which is more expensive. Fore-and-aft stringers are laid below the thwart-ship timbers. The posts are bolted to both the fore-and-aft and the thwart-ship timbers, the bottom planking being laid athwart-ships. Clamps are used above the thwart-ship timbers the same as in the other form of construction, the

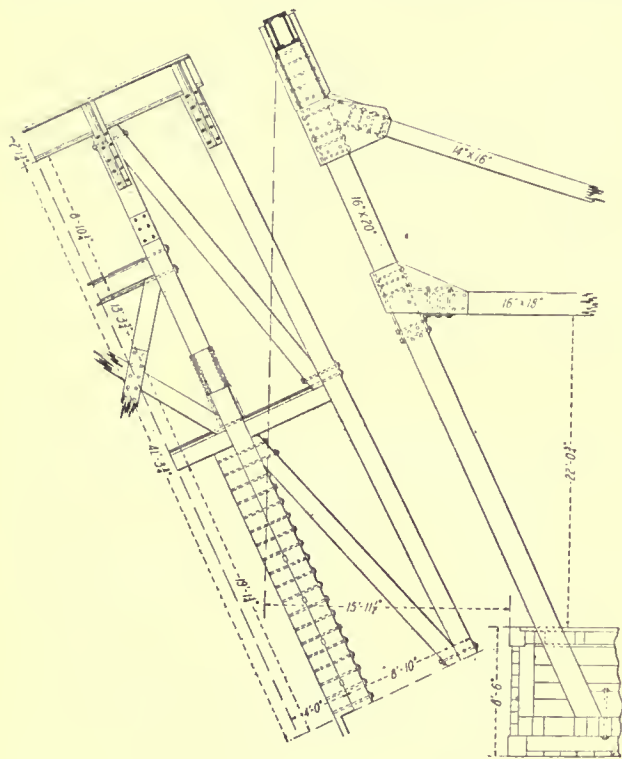

CAST STEEL SPUD-POINT.

weights of all machinery should be determined and the hull built accordingly. The depth largely depends on the weight to be supported, the beam on the gold-saving area desired, the length and width of well on the dimensions of the digging ladder, and the digging ladder in turn on the depth of gravel to be dug. The distance from well to stern is determined by the length of screen and the general distribution of machinery fore and aft. The hull rides on an even keel when digging at an average depth and should have a freeboard of not less than one-fourth its total depth. The cross-section is rectangular, with the deck slightly crowned. Thwart-ship frames are used, the bottom planking being spiked to the bottom thwart-ship timbers, the decking to the upper timbers or deck beams, and the side planking bolted to the upright side posts. Besides these, two or more pairs of posts are put in each frame, and to these the well planking and bulkheads or fore-and-aft trusses are bolted. Clamps or fore-and-aft strengthening timbers are bolted inside the frames at the corners where the posts join the deck beams and bottom thwart-ship timbers. The size of these clamps depends on the size of the hull. Drift bolts are driven in the side planking and bulkheads, each bolt passing through 2 1/2-in. planks. They may be put in as thickly as desired, and add considerable strength to the planking and bulkheads. Four-inch deck and bottom and 6-in. side planking is commonly used. The stern is often planked with the same size as the sides, put edgewise instead of flat. At the point where the spuds are placed a short bulkhead or extra bracing is often used. Just aft of the well and below the bucket drive, one or more vertical cross-trusses are often used, likewise horizontal cross-bracing is put in on top of the thwart-ship frame timbers along the compartments adjacent to the well and extending some distance aft from the well throat.

difference being that there is an extra set of fore-and-aft timbers, to which the bottom planking is spiked, this planking running athwart-ships instead of fore and aft. This construction requires more lumber and labor, but is stronger, and by using thwart-ship planking, full lengths can be used, doing away with all butt joints. The tendency of dredge hulls is to sag along the fore-and-aft centre-line. Where fore-and-aft planking is used, this movement of the hull tends to open up the seams, but where the thwart-ship planking is used, the strain is lengthwise of the planking. When a hull is new these weaknesses do not show, but after years of service all such little things count, and since the life of a hull determines the life of a dredge, it pays in the long run to use every precaution possible to add to the stability and length of life of the hull. Solid fore-and-aft bulkheads are recommended, also the use of well plates made up of 6 by 14-in. planking (for the 7 to 9-cu. ft. dredge), laid horizontally below the deck beams and filling the roof of the first compartment on each side of the well for 30 ft. each way fore and aft from the throat of the well. These well plates are particularly useful in dredges having long well holes.

Another plan which will add strength at small cost is to put in diagonal wooden braces from the fore-and-aft timbers near the bottom of the intermediate bulkhead to the clamp near the top of the well hole. This will aid materially in preventing sag toward the well hole. Still another form of strengthening construction being used, particularly on the larger boats, is an overhead thwart-ship truss with heavy hog-rods running diagonally from the upper chord near the sides of the dredge to the bottom of the hull at the well, thus preventing sag at this point. The bottom, sides, bow, stern, and deck are all calked with oakum and the seams pitched or similarly treated. The inside is treated with carbolineum, Stockholm tar, painted, or left without any treatment whatever. On the outside below the water-line the planking may be painted or not as desired. Above the water-line all timber work is thoroughly painted. Before putting timber together, all joints are painted with white lead, mineral paint, or coated with tar or carbolineum. The deck beams are extended

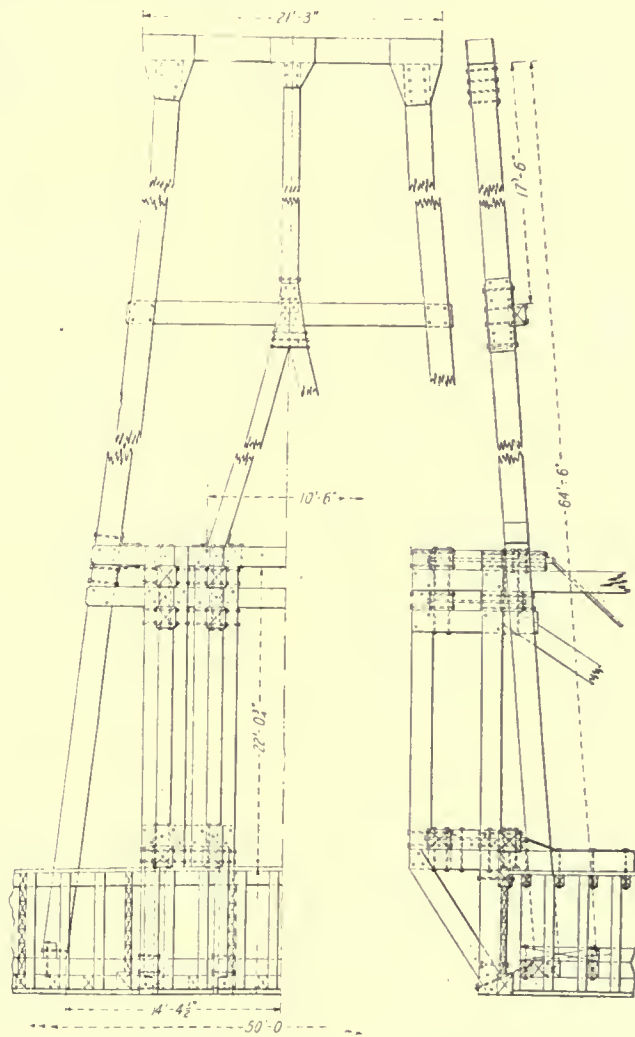

BOW GANTRY, 9-CU. FT. DREDGE.

beyond the sides of the barge at the after portion of the dredge. Braces are put under these in order to support the housing uprights. This gives extra room for gold-saving area or passageways. Hatchways are provided for entrance into each compartment, also a system of ventilation should be installed, using either mechanically driven fans or natural ventilation induced by cowled ventilators. Proper ventilation will do much toward prolonging the life of the hull. Sea-cocks are often installed in order to sink the dredge in case of a fire which has gone beyond hope of being extinguished. If sea-cocks are used they should be placed near the bows, where a hot fire in the housing will not prevent their being approached and quickly opened.

Main Truss.—A large number of the California dredges have a truss along the sides of the well and extending from bow to stern gantry, with wooden chords, posts, and braces, and steel hog-rods. This truss is made 15 to 25 ft. high, the upper chord often being used to support the upper tumbler bearings and the upper end of the digging-ladder. In the earlier dredges there was a tendency for the hulls to go down at bow and stern and hump up near the throat of the well. This truss assists in preventing this condition, strengthens all the gantries and spud frame, and makes an excellent support for the housing, screens, etc. It should be designed as a truss supported at the middle with weights suspended at each end.

Bow Gantry.—At the bow is a gantry which supports the forward end of the digging-ladder, the details varying in the different dredges. A steel cap, of box or I-beam section, on four posts, is a common type. In some dredges the four posts are parallel; others have two posts parallel to the well sides and two sloping inward joining the first at the cap. Still others have the four posts parallel for half their length, the two outside ones being cut at this point, and from here diagonal braces run to the intersection of cap and inside posts. The whole gantry is inclined forward in order that it may have a more direct pull on the digging ladder. In a good many of the California dredges the gantry posts go through the deck and are stepped on heavy foundation timbers or castings near

STERN GANTRY, 9-CU. FT. DREDGE.

the bottom of the hull. A few dredges have rigid foundations for these posts on the deck, and at least one uses a socket casting into which the posts fit loosely. This gantry has thwart-ship bracing and is guyed by ropes or tie-rods to the main gantry, hull timbers, or both. The top chord of the main truss runs to the middle portion of this gantry and is fastened to it by means of steel plates. It is also customary to run a brace diagonally from near the cap to the top of the first truss post. Some form of pin and plate clamp is provided for the bow-gantry cap, to which is attached the ladder-hoist blocks and gantry guys.

Main Gantry.—The main gantry is a support for the bucket-drive and the after end of the digging-ladder. It has a very severe duty to perform and should be built in a most substantial manner. I prefer to place a post under each bearing and use heavy lattice-bracing between the posts. Too many plates should not be used to tie the timbers together, and matters should be arranged, if possible, so that all bolts will be accessible. Where many plates are used it is very difficult to assemble the parts, and in case of repairs the delay is great in taking apart

and reassembling, owing to the difficulty of lining up the holes in the different plates.

Stern Gantry.—The stern gantry supports the spuds and the stacker ladder, and must be made high enough to raise the spuds so that they will nearly clear the bottom of the hull. It is inclined slightly aft so that the spud hoist-blocks will be vertically above the centre of the spuds. The design is simple: two, three, or four posts being used, with a wooden or steel cap. Clamps are used for the spud hoist-blocks, ladder-support, and guy ropes. The posts may rest on foundation timbers or castings placed near the bottom of the hull or on the deck.

Spud Housing.—At the stern of the dredge the two spuds are enclosed in a housing which allows them to slide up and down but holds them in a vertical position. At some point above the deck, usually at the elevation of the upper chord of the main truss, heavy timbers are framed around the spud, with tie-rod connections to the hull or main gantry. This framing, together with the tie-rod connections, resists the tendency of the upper part of the spud to move backward as the buckets engage the gravel and thrust the hull toward the rear. This clamp must be made strong enough to withstand the full digging power of the dredge, increased to some extent by the slight fore-and-aft movement of the hull and the consequent momentum of the full weight of hull and machinery. I do not approve of running the tie-rods to the main gantry, since, no matter how strong this part is made, the constant pulling and jerking on one side will tend after a time to throw the bucket-line shafting out of line. The guy-rods should be run into the hold or to some other part which does not support shafting. Many different spud-housing designs are used, but the present tendency seems to be to use heavy castings covering a large area of the stern to resist the forward pressure of the spud and a structural or cast-steel clamp 20 ft. or so above the deck. In order to keep the spud from moving backward, heavy steel keepers are used which can quickly be removed when it is necessary to change spuds. The timber construction will work well enough, but it is likely to get loose in time, and it is difficult to design a wooden structure so that it will be at the same time strong and easily removable. Whatever form of spud housing is used, it should be so enclosed that small rocks cannot lodge where they will be caught between the spud and its guide.

Housing.—The after portion of the dredge is housed in, this housing covering the gold-saving tables, pumps, main winch, ladder hoist, and transformers. The after central portion is extended up and covers the screen and screen-drive. A covering should also be provided for the bucket-drive, but this is not essential. The roof of the housing is made with a slight crown or slope to the sides, and covered with painted canvas, ship fashion. The roof joists should be made heavy enough to support a considerable weight, since in repairing it is often convenient to lay down one of the big gears or the like, and for this reason the flooring should be at least $1\frac{1}{4}$ in. thick, or made of two thicknesses of planking. The stern and sides along the gold-saving tables are not usually boarded up. It is thought that an unobstructed view lessens the danger of amalgam stealing.

Pilot-House.—The pilot-house, from which the digging motor and winches are handled, is usually placed on the starboard side of the upper deck, above the main winch and a little forward of the bucket-drive. This is the common position, but the pilot-house on the central line of the dredge above the bucket-line and just forward of the bucket-drive, seems preferable. An objection to this position is that the lever connections to the winches are a little more complicated, but it gives an excellent view in all directions around the dredge and down the bucket-line. By proper arrangement of gratings the main winch may be seen. The bucket-drive, stacker, and spuds are also within sight of the winchman. In my opinion there is no question as to the proper position for the pilot-house, and all my dredge designs have their pilot-houses well up in the centre of the boat.

CONSTRUCTION COSTS.—The construction costs vary greatly, of course, according to the quality of workmanship and material desired, facilities of the builders in the way of properly equipped shops and foundries, and the geographical situation of the ground on which the dredge is to be built. The following may be considered a fair average of many cost records in California, for rough estimating purposes. For all the machinery, including motors, pumps, wire rope, electric supplies, etc., $12\frac{1}{2}$ ¢. per pound, delivered on the ground; for erecting, $4\frac{1}{2}$ ¢.; or a total of 17¢. per pound for the machinery erected. The lumber costs about \$30 per 1000 ft. at Portland, and this, together with freight, bolts, nails, hog-rods, steel plates, oakum, paint, etc., will make the hull material cost about \$50 per 1000 ft. of lumber used; labor of building costs about \$40 per 1000 ft., giving \$90 per 1000 ft. as a total cost of the completed hull. In addition the direct costs chargeable to hull or machinery, insurance, traveling, superin-

PILOT-HOUSE OF A MODERN DREDGE.

tendence, camp equipment, temporary buildings, shop, derick, office expense, design, etc., amount to between \$10,000 and \$25,000, depending on whether new designs have to be made, what construction tools and equipment are on hand, the size of the dredge, and character of the ground on which it is to be built. For a complete dredge, \$180 per ton, on a basis of its displacement, is a fair average.

Queensland Gold Yield, 1911

The yield of gold in Queensland for December was 33,873 oz. fine, of the value of £143,883, this being a decrease, when compared with the corresponding month of 1910, of 9910 oz. in quantity and £42,095 in value. This comparative decrease is to some extent accounted for by the fact that the yields from Cloncurry and the Etheridge recorded in the December returns for 1910 were for two and three months respectively. The December yield showed an increase of 940 oz. at Charters Towers, while there were decreases—at Croydon, of 490 oz.; at Gympie, of 2850 oz.; at Mount Morgan, of 2819 oz.; at Ravenswood, of 525 oz.; and the Rockhampton fields, of 376 oz. The record for the twelve months is incomplete, as returns have yet to come in from metallurgical works, but the yield so far recorded for the year is 381,845 fine ounces, of the value of £1,621,973. Comparing these figures with those available for the same period of 1910, a decrease (which, of course, is only approximate) is shown for the year of 56,939 oz. in quantity and £241,862 in value. The published figures for the first nine months of 1911 showed that the increase that had taken place in the production of the industrial metals more than compensated for the decrease in the gold yield; and as the price of copper has since improved, the position should be still better when the year's returns are complete. On the whole, there seems little doubt that the total mineral production for 1911 will show a substantial improvement over that of 1910. The dividends paid by gold mining companies during December totaled £72,337, and for the year £382,729.—*Queensland Government Mining Journal.*

Mineral Resources of Bolivia

By CARLOS SANJINES

The Republic of Bolivia, situated in South America, covers an area of 709,000 square miles. This vast territory, which now has a population of 2,500,000, can easily hold 30,000,000 inhabitants. The mineral richness of its soil as well as the fertility of the land offers brilliant prospects to capital and labor. The active construction of railroads going on and the guarantee received by capital are the principal elements making for the rapid progress of the country. A few years ago Bolivia obtained from the Brazilian Government an indemnity of \$10,000,000 in exchange for a tract of territory on the Acre river. The amount was not spent in arms and ammunition, because the country loves peace and understands thoroughly that only under peaceful conditions is a nation able to develop its commerce and industries; the money instead was invested, together with some American capital, in railroads, many of which are in actual operation and others under construction.

It is not proposed to give here a detailed review of the variety of products which Bolivia has in abundance in the three kingdoms of nature. This article will be devoted simply to sketching the mineral resources that at the present moment are attracting the attention of the mining people of the United States.

GOLD MINING

Before furnishing some data about the gold industry, a general description of the places in which this precious metal is found may be quoted from the 'Bulletin of the International Bureau of the American Republics.'

"The distribution of the metallic belts in Bolivia has always been a matter of wonder to geologists, Raimondi having made the statement that the Bolivian plateau 'is a silver table supported by gold columns.' The gold-bearing belt of the country is divided into three regions. The first extends from the western boundaries of the Republic in the Inambari basin to the eastern frontier on the upper Paraguay. This region embraces the whole mountainous section of the Provinces of Caupolicán, Muñecas, Lareeaja, Cereado, Yungas, Inquisivi, and Loaiza in the Department of La Paz; thence it continues through the Department of Cochabamba and ends at the Santa Cruz Paraguayan boundary. The second region starts in Lipez, extending south through the Province of Chayanta, Sur Chichas (Department of Potosí), Mendez (Tarija), Cinti, and Acero (Chuquisaca), as far as Santa Cruz plains. The third region, which perhaps is the richest, extends toward the northwest of the Republic as far as Carabaya (Peru) and the head of the rivers Madre de Dios, Acre, and Purus."

Exportation.—The amount of the exportation cannot be determined exactly, because the principal part of the production is smuggled out to avoid the payment of the small tax of 20c. on each ounce exported. In 1902 an estimate was made based on reliable private information, and the amount of the export was figured at more than 1300 lb. per year. Ten years have elapsed since then, and in that period of time more capital has gone into the gold industry and many new mines have been discovered, therefore the production of that metal is at present evidently of great importance.

It can be understood that the results obtained under the primitive methods of gold mining which are still in use at the present time in almost all the mines, should be greatly increased by the introduction of modern methods such as those adopted in Alaska and other mineral regions of the United States. It can be stated without fear of error that any person familiar with the mining industry and with small capital to invest, will be successful working either by himself or associated with natives in Bolivia. Many own rich mines, but are unable to develop them on account of lack of capital, and having but a

superficial knowledge of gold mining. The work progresses, therefore, on a very small scale.

For centuries the placers of Tipuani and Suhez have drawn the attention of prospectors, and at present, among the hundreds of mining concessions, are foremost. In them centres the principal interest, according to private reports received in this country by friends of the American miners in the Bolivian goldfields. It will be useful to give the following details about those places.

Tipuani.—Tipuani is situated in the Province of Lareeaja, Department of La Paz, about 150 miles north of the city of La Paz. The river of the same name flows from the Mount Illampin, formed by several streams, and empties into the river Mapiri. Both rivers are famous for the presence of gravels containing immense quantities of gold. According to published reports, at a depth of 300 ft. rock bottom could not be found; the proportion of the gold increasing with the depth of the gravel. Though

MAP OF BOLIVIA.

those mines have been worked for more than three centuries and contributed on a large scale to the riches of the Spanish Crown under the Spanish domination, they are far from being exhausted. On the contrary, they offer splendid chances to the prospector. Tipuani gold is from 22 to 23.50 carats fine.

Suhez.—Suhez is in the northwestern part of the Department of La Paz, Province of Lareeaja, about 200 miles from the city of La Paz. The river Suhez is as important as the Tipuani, because of the great amount of gold that its waters carry. At the headwaters of the river gold is found in conglomerates and recent gravel. Along its bed gold-bearing gravel exists in paying quantities, there being about 100,000,000 cubic metres of gravel yielding gold at the rate of 40c. per cubic metre, according to the report published by the Bureau of American Republics in 1904.

Other Localities.—Besides Tipuani and Suhez, there are in Bolivia many more placers and mines of no less importance. San Juan del Oro, Los Cajones (river); Chuquigüillo (river), about three miles from La Paz; and the mines of Araca, Arque, San Jose, Sorotao de Chiquitos, etc., are all comprised in the first region. Amayapampa, Suipacha, Esmoraca, Chuquihuqui, San Juan, and

tributaries of the river Guapay are comprised in the second region. It must be noted that not all the placers and mines referred to are under actual exploitation, many of them being idle because of lack of capital, and thus affording a good opportunity for new applicants for mining concessions.

Though the following concerns the ancient history of the mining industry in Bolivia, it is of interest in this connection: "According to the data gathered by the General Bureau of Statistics and the estimates of several scientific men as Humboldt, Stobier, and others who made a special study of the matter, the mines of Bolivia have produced, from the year 1540 to 1750, a lapse of 210 years, the enormous amount of £420,000,000, about \$2,100,000,000."

TIN MINING

Among the mineral products of Bolivia the most important one is tin, in the development of which large capital is invested. The great value of this metal, which fluctuates around £190 per ton in the markets of London, has led the miners of Bolivia to devote their capital and energies to the working of tin mines in preference to those of silver and other metals. This fact has greatly stimulated the industry. Most of the companies have modern and

CLAVIJO DITCH IN THE SUCHIEZ DISTRICT.

well designed plants. The output is large, as will be seen by the following statistics.

In the year 1910 the total exportation of metals from Bolivia reached the amount of 54,732,000 kg., representing a value of \$46,716,774. Of this amount, tin occupies the first place, as its exportation was 38,548,441 kg., of a value of \$37,006,503. The balance is distributed among the other metals, such as silver, copper, zinc, gold, bismuth, antimony, and tungsten. For 1911, the statistics of the first six months of the year only are available. They show total exports to the amount of:

	Kilograms.	Value.
Tin	19,052,267	\$25,149,529
Other metals	7,779,029	5,914,194
Total	26,831,293	\$31,063,723

It should be taken into consideration that the value above stated is in Bolivian money, \$1 United States currency being the equivalent of 2.50 bolivianos.

Judging by the foregoing figures, it can be asserted that the exportation of metals at the end of the year 1911 reached more than 60,000,000 kilograms.

The probable production of tin in all the world, according to available statistics, is about 100,000 tons annually. The principal output comes from the English possessions in the East Indies, whose contribution is a little more or less than 50,000 tons. Bolivia's output is nearly 40,000, which puts Bolivia in the second place among the tin-producing countries of the world. In some foreign statistics, Bolivia does not appear as a contributor of tin on such a grand scale. Part of its product is classified erroneously as Chilean or Peruvian tin. This happens because Bolivia,

being an inland country, has to use for its shipments the ports of Antofagasta (Chile) and Mollendo (Peru).

After the foregoing information about the industry of Bolivia, two more points remain to be explained which may interest the mining people desiring to go there—that is, the substance of the law relating to the adjudication of mines; and the best way to reach the country, as well as the cost of the trip and other details.

MINING REGULATIONS

The mining laws in Bolivia are very liberal, all the foreigners enjoying the same privileges and rights as the natives. Any person having legal capacity to contract may ask as many as thirty (30) mineral concessions (*pertenencias*). The measurement for each concession (*pertenencia*) is fixed at 100 square metres (about 327 sq. ft.) in the

STREET SCENE IN LA PAZ, BOLIVIA.

direction desired by the applicant and extending indefinitely in depth.

The procedure is as follows: Any person finding deposits, placers, veins, etc., has to make his application to the Prefect of the Department in which the claim is situated, accompanying the application with a sketch showing clearly the position in which the mining claim shall be surveyed, and pointing out also its position in regard to adjoining claims. The application must be filed on stamped paper of the value of 10 bolivianos (about \$4).

The Prefect, after having published the application in the papers for some time to see if there is any opposition to the claim, shall issue the decree of concession, and the applicant becomes the owner of the mine, paying the annual tax of \$5 Bolivian (about \$2 U. S. ex.) for each *pertenencia*.

An application is considered abandoned if the survey and setting of landmarks are not made within 70 days from the first publication. Any person may denounce the abandonment of an application, asking to be granted the same, when the owner has failed to comply with the laws relating to the matter.

For prospecting it is not necessary to get special permission. Any person may do that kind of work, giving notice to the authorities of the district in which he intends to prospect.

Machinery and tools for mining purposes may be imported into the country free of duty.

ROUTES OF TRAVEL

It is advisable for all persons interested in mining and other business in Bolivia to go first to the city of La Paz, which, though not the capital, is the largest and most important city of that country, being the place of residence for the Bolivian officials, the seat of government, and the commercial centre of the country.

How to Reach La Paz.—The trip to La Paz may be divided into three stages: (1) from San Francisco to Panama; (2) from Panama to Mollendo; (3) from Mollendo to La Paz.

(1) From San Francisco to Panama the steamers of the direct line established by the Pacific Mail Steamship Co. sail from San Francisco fortnightly and make the journey in 13 days, the cost of the first-class passage being \$85. The steamers of the regular service, which make calls at the different ports south of San Francisco, require 25 days and the cost is \$125.

(2) From Panama to Mollendo there is a choice of two lines: the Pacific Steam Navigation Co. and the South American Steamship Co., which connect with the steamers of the Pacific Mail. The regular trip from Panama to Mollendo is made in about fourteen days, but the South American Steamship Co., as well as a Peruvian company recently established, have some fast steamers which make the trip in less than eleven days. The price of first-class passage is about \$150.

A quick trip from San Francisco to Mollendo, therefore, could be made in 24 days at a rate of \$233.

(3) From Mollendo to La Paz the journey is by rail and boat. A railroad connecting the port of Mollendo and the city of Puno (Peru) makes the trip in two days, arriving at the latter point in the evening. At Puno a steamer is taken to cross Lake Titicaca, the highest navigable lake in the world, the journey lasting all night, and on the following day the train is reached at Gnaqui (Bolivia). It conveys the passengers to La Paz, taking about three hours. The journey may be summarized as follows: from Mollendo to Puno, 2 days by railroad; Puno to Gnaqui, 1 night by steamer; Gnaqui to the city of La Paz, Bolivia, 3 hours by railroad. The entire trip from Mollendo to La Paz is made in three days and the cost does not exceed \$25.

The information given shows that the journey from San Francisco to La Paz could be made by the Pacific route in less than one month for \$260 in round figures. The journey from San Francisco to Panama may be shortened, by way of New York, by three or four days if the traveler makes the exact connection with the steamers of the Panama Railroad Co., which make regular trips twice a week, between New York and Colon, the time being about five or six days. The train from Colon to Panama does not take more than four hours. Time could be saved by this route, but the expense is greater by more than \$100.

The Vanadium Industry in France

The Santa Marta company has purchased the factory of Cire les Mello, Department of Oise, for the purpose of carrying out the patents granted to Mr. Perret for the manufacture of vanadic acid. The works are capable of producing six tons of acid monthly, and the company will also make ferro-vanadium and other alloys. In a consignment delivered to the Marine Workshops at Ruelle, the quality was so highly appreciated that other orders speedily followed, and it has been adopted as the market standard. The products of the Santa Marta company were awarded the grand prix at the Turin exhibition. The growing employment of vanadium in the making of steels, in the opinion of the *Echo des Mines*, assures the future success of the company.

Tungsten and Its Uses

By ROBERT P. SKINNER

*Germany offers the largest market for tungsten ore in the world, although the domestic use of the metal is exceedingly limited as contrasted with its uses in England and the United States, which altogether absorb probably two-fifths of the total production. The metal itself is employed chiefly for hardening steel, and its varied applications are increasing rapidly.

Hamburg importers are in a position to sell offerings of ore practically in unlimited quantities. The price is based on the content of tungstic acid (WO_3), the usual content running from 60 to 65%. Ores under 60% are not in demand. The ordinary commercial terms are Hamburg weight, analysis by the state laboratory, shipments in bags of 50 kg. (1 kg. = 2.2046 lb.), price per ton of mineral, and percentage of tungstic acid. One thousand tons of 60% ore should produce about 400 kg. of metal, worth (January 1912) 5.75 marks (\$1.37) per kilogram, containing 97% of metal, 0.1% of carbon, and free from impurities.

The total importations of tungsten ore into Germany in 1910 amounted to 2491 tons, against 2520 tons in 1909. The exports of the metal are included with exports of chromium and cadmium, the total shipments under the three heads being 1643 tons in 1910 and 1213 tons in 1909. American manufacturers imported ore and its products from Hamburg alone, as follows:

	1910.	1911.
Tungsten ore	\$143,629.43	\$53,410.29
Tungsten metal	126,967.05
Tungsten filament lamps.....	14,938.54

The metal is obtained by reducing the oxides or chlorides in a current of hydrogen, or by means of carbon in an electric oven. According to German patent No. 141811, the raw material is melted at a temperature of 300°C. with sodium bisulphate, after which the temperature is raised to about 800°, and lime or lime salts and alkaline chlorides are added. Sodium bisulphate must always be contained in the mixture in excess of other material. If the method is thoroughly carried out, all tungsten is obtained in the form of tungstic acid, or sodium tungstate. The acid is melted and reduced to metallic tungsten.

Tungsten lamps are incandescent electric lamps consisting in part of threads made of metallic tungsten. Different methods are employed in their manufacture. Bluecher's 'Handbook of the Chemical Trades' thus describes the process:

The metallic tungsten, used in the form of threads in incandescent lamps is obtained from wolframite. Tungstic acid (tungsten trioxide, WO_3) is imported into the United States for the manufacture of these threads. WO_3 is obtained from wolframite by heating together finely ground wolframite and HCl (hydrochloric acid); thus oxide of tungsten and soluble chlorides of Fe (iron) and Mn (manganese) are formed. The three products are carefully washed about a dozen times with water. They are then allowed to settle, when the water is again drawn off and fresh water added. The precipitate of tungsten oxide is dissolved in ammonia, whereby ammonium tungstate is obtained. This is filtered and heated and finally boiled together with HNO_3 (nitric acid) to remove the iron and manganese.

Tungstic acid is obtained from thoroughly washed ammonium tungstate by heating it to a glowing point. This result originated in the manufacture of metallic thread, according to Auer's method (Osram lamp). He removes the oxygen and thus obtains metallic tungsten, which is mixed with an agglutinant and forced through fine diamond matrices. Just and Hanan apply the method of substitution. Kuzel applies the colloid process, according to which the metallic tungsten is alternately treated with strong boiling acids and alkalis. It is, of course, thoroughly

*Abstract from a Consular Report.

washed each time until it is converted into a colloid. The colloid is then precipitated, the liquid drawn off, and the residue, which is gelatinous, is forced through the diamond matrix. Lamps furnished with these threads are called Kuzel lamps.

Another method for the production of colloidal tungsten is to send an electric current under water through two electrodes made of metallic tungsten. In this way small particles of tungsten are thrown off from the electrodes and form colloidal tungsten. The products of the three methods are of equal value. The tungsten thread coming out of the matrix is dried in an oven and then heated in an electric oven up to 2000°C. to drive out the volatile ingredients. Then an electric current is allowed to pass through the thread in an atmosphere of indifferent gas, and the thread for the lamp is thus obtained. The current consumption of the tungsten lamp is from 1 to 1.3 watts per Hefner candle-power, whereas the carbon-thread lamps consume 2.3. The disadvantages are the higher price and greater fragility of the thread. Against this, tungsten thread has a longer life (1000 burning hours against 450 of the carbon-thread lamp), and it is also much less sensitive to current fluctuations. The tungsten lamp also gives a better light.

Water in California Oil Wells

By AN OCCASIONAL CONTRIBUTOR

The operators of all oilfields become sooner or later familiar with the disastrous result following the appearance of water in the oil wells. To such an alarming extent has water encroached upon most of the oilfields of California that legislation has been enacted to remedy an increasingly serious situation. The state law, however, fails to provide a penalty or to supply an appropriation which will make it possible to apply a remedy. Several efforts have been made in Kern county to take up this matter in a coöperative way, but are thus far only partly successful.

About the middle of February the State Mineralogist, W. H. Storms, was requested to act as a mediator and harmonize conflicting opinions among oil operators. Recently Mr. Storms visited all of the oil districts of Kern county in company with W. N. Forker, County Water Commissioner, and several others interested in the oilfields. The seriousness of the situation is apparent. As an example of what is now taking place there, the fact may be mentioned that at the time of his visit to one of the noted gushers of the Kern field, a production of several thousand barrels of clear oil was being made daily. Only one week later this same well was producing water, the quantity of which is rapidly increasing. All over the fields, wells which a few months or a few weeks ago were profitable producers, are beginning to show signs of water, some of them running as high as 85% water.

There is no doubt but that an industry producing at least fifteen millions of dollars in Kern county, alone, will be completely destroyed unless heroic measures be taken to remedy this unfortunate condition.

As a result of the visit of the State Mineralogist to Bakersfield and the oilfields, a meeting of oil men was held on Thursday, February 29, at which time it was decided to call a meeting of oil operators for Saturday evening, March 9. Invitations to attend this convention have been sent to all operators in Kern county, the large and small interests alike being invited to have representatives at the meeting, at which it is expected to perfect a permanent organization and to appoint a committee on ways and means, legislation, and other important matters.

There appears to be more unanimity than ever before as to the necessity of prompt and effective action on the part of all concerned to control the water, which is steadily encroaching upon the oil sands, and it is believed that there will be no trouble in securing the necessary funds for immediate relief, as the officials of the larger companies say they are willing to share liberally in any movement looking to the desired end.

Tin in Nigeria

LONDON CORRESPONDENCE

Progress of the alluvial tin industry of northern Nigeria is being followed closely in London, and the market for the shares of the various companies is the only bright spot in speculative business nowadays. The monthly outputs are scanned eagerly. It goes without saying that most of the companies are absurdly overcapitalized, and that in many cases company-mongering has received more attention than production. It is only fair, however, to point out that several of the companies have started without undue inflation of capital, and have been conducted with the aid of the best possible advice. For instance, the Rayfield Syndicate has a capital of £20,000, in 80,000 shares of 5s., 40,000 of which were issued at 100% premium (or 10s. per share). The results obtained have been highly gratifying to the subscribers, six-penny dividends having been paid monthly since October last, and at Christmas a bonus of 1s. per share was added. The Syndicate originally acquired five properties known as Shen, Lafon, Delimi, Wono, and Kuru. The Kuru was sold to the South Bukuru company for cash and shares. Subsequently the Syndicate secured a property now known as Sabon Geri, and it bids fair to become one of the romances of mining. Situated within a dozen miles of Naraguta, the richness of the tin-bearing streams and banks appears to have escaped the serious notice of the early prospectors. The richness and extent of the deposits has been confirmed by reputable engineers, and further work is to be done in exploring the lodes. Another undertaking is the Nigerian Tin Corporation, which conducts a general mining and finance business; it has four productive properties, securities of the quoted value of £18,000, some £15,000 in cash, loans, and tin in transit, and other share interests. As the subscribed capital is only £45,782, the directors appear to have acted discreetly, and to have had their share of good fortune. A dividend of 10% was paid in February 1911, and 71 tons of tin was produced by calabashing alone to December 31, 1911. The sluicing plant is now ready for operation, and a greatly increased yield is anticipated. A third company, the Northern Nigeria Mining & Exploration Co., has a nominal capital of £10,000, of which £8838 has been issued; £6000 has been repaid in a dividend, and the company now owns areas of approximately 18 square miles. Altogether, six companies are likely to make money: the Bisichi, Rayfield, Naraguta, Kano Tin Areas, Jos Tin Area, and Tin Areas of Nigeria. The total output of northern Nigeria for 1911 is estimated to have been 1700 tons of concentrate assaying 70% metal. While the published returns are defective in being given in terms of a variable concentrate, and not in metal, it is a fact that the average grade of the product shipped to England is high, ranging usually between 70 and 74%. But as some of the so-called tin reported has been a low-grade concentrate, some doubt has been thrown on current statistics. Before long the railway connecting the Bauchi plateau with the coast at Lagos will be completed, and operations will then proceed more rapidly and economically. Northern Nigeria has every promise of coming farther to the front as a mining centre.

FLUORINE may be easily detected, according to E. Rupp, by placing the crushed material in a platinum crucible 3 cm. high, or a lead tube, closed at one end, 5 cm. long by 2 cm. diam. Three drops of water and 1 c.c. of H_2SO_4 are added. The vessel is then closed with a rubber stopper through which passes a smooth glass rod, on the tip of which a drop of water is suspended. On heating for a half hour on a water-bath, if fluorine is present a coating of H_2SiO_3 , Na_2SiF_6 and $CaSiF_6$ appears on the tip of the rod. The etching of the rod may be detected by rubbing it on the teeth. Even traces of fluorine are said to be detectable thus. If a taller crucible is used, the rod should be pushed through far enough so that its tip is only 2 cm. above the mixture within.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Employers' Liability and Accident Insurance

The Editor:

Sir—I have read with interest the articles by A. J. Pillsbury, which recently appeared in the *Pacific Rural Press*, on the Roseberry Liability Act, in which he sets forth reasons why the farmers of California should not object to this act. He emphasizes the fact that this burden will be shifted upon the ultimate consumer. This is the case in every industry except gold mining. The very words 'gold mining' are synonymous with great wealth and enormous profits in the minds of all except the gold-mining fraternity. A good gold mine is a 'gold mine', but how many profitable gold mines are in operation today in California? I believe they can be counted on the fingers. Compared to the number that are in operation, they are few, indeed. Many of the mines are struggling along, and have been, for years, by the help of assessments.

Gold has a fixed value, as everyone knows, and any added expense, caused by increase of wages, shorter hours, increased cost of supplies, and liability for accident damages, cannot be shifted upon the ultimate consumer, as has been, is being, and will be done by all other industries, and which is largely responsible for the increased cost of living. Were all the gold mines in California that are operating but not profitable to close down suddenly, the whole state would suffer from it. The thousands of men employed would either displace workers elsewhere or be idle until new enterprises absorbed them. This is not saying anything about the thousands that are benefited indirectly by the gold-mining industry, and the new liability law may prove the 'last straw' with numbers of them.

I fully agree with Mr. Pillsbury that the shock of accident, with its accompanying pain, suffering, and sorrow, is enough for the unfortunate victim to bear, without the added misery of having the 'wolf' hovering about; but I do not agree with him, that the employer should alone bear the costs. I insist that the state, at large, should share in it, since the whole state is benefited by the gold-mining industry. Professional men, real-estate owners, and those industries in which labor runs little or no accident risk, should share the accident costs. This could be brought about by the compulsory insurance of all labor, the premium costs to be divided into three portions, of which the employee should pay, say, at the rate of one-quarter, the employer one-quarter, and the state one-half, or in such proportions as might be decided upon. In this way, the burden would not be too hard on anyone. If this course were followed, the poor ultimate consumer, already overburdened, will escape this liability burden, except, of course, from the gold-mining industry, which cannot shift it. The burden will come to those fully able to bear it, and without their feeling it. I would suggest that either the older and married men's premiums be less, or else that they carry greater insurance, because old and married men are far more careful than the young ones, with consequent less risk to assume. Another thing I wish to say about this liability law is, that nearly all mining men, especially those who have employed Mexican labor, will agree with me when I say that there are plenty of men who would not hesitate to cut off a hand or foot for \$1000, were they sure of collecting it. Of course, they would do it in such a manner as to make it appear an accident, which can readily be done underground. Should a tottering concern bear such expense alone? In gold mining there is always the hope of 'striking it rich' if the

struggle can be continued for a while longer. I mention this in answer to those who would say: "Let the concern fail, since it is so near its end." I have heard this remark from a walking delegate who was advising a strike. The concern referred to employed between 400 and 500 men, is still alive, and the remark was made years ago. I have read and heard that in Europe many persons maim and cripple themselves to escape conscription, or for the purpose of begging; why not, then, to collect substantial damages? But this is only a side issue.

I believe in compulsory insurance, with the state sharing a good part of the costs. I am a property holder, willing to pay my proportion, and only sorry I wouldn't be entitled to pay by the thousands.

F. J. MARTIN.

Angels Camp, California, February 21.

Cross-Fractures and Ore-Shoots

The Editor:

Sir—Your issue of September 16, 1911, contains a letter by W. N. Cummings on the importance of vein intersection. Mr. Cummings quotes such authorities as J. F. Kemp, J. E. Spurr, and S. F. Emmons, and he claims that in his opinion the significance of this particular phase of geology in the search for ore is insufficiently appreciated. In respect to veins depending on substitution or metasomatic filling, I agree. By this process a quite narrow intersecting fracture caused by the oscillation resulting from extensive plane faulting may become transformed into a large repository of commercial value.

In my experience I have met such examples, and I have also noted cases where such possibility of intersections has been insufficiently recognized in development program. In this respect, I recently examined a mine in which a branch vein of phenomenal richness was discovered intersecting a main vein which owed its origin to extensive plane faulting. The rocks are andesite, with their characteristic predominance of soda-lime feldspars, together with rhyolites and basalts, the junctions showing considerable brecciation in common with such effusive phenomena. There appears to have been a succession of eruptions, the older being different varieties of andesite, and the younger of rhyolites. It is in the older eruptives, or andesites, that the principal mineralized zones occur. In many places there are indications that some rhyolitic flows had been deposited before the profound shearing which formed the inception of the mineral deposits; as is shown in places by impregnation and fracturing of the rhyolite.

The mineral deposits of the district owe their existence to what appear to be three profound shearing zones. These fracture planes are not continuous, but the mineral zones are all more or less in alignment and there is little doubt that their formation was simultaneous. Diagnosis of the cause of the fracturing is difficult, and it is impossible to state definitely whether the present vein systems are the result of contraction through cooling or profound laccolithic pressure. The surface has all been greatly eroded, destroying much that would be valuable to geological prognosis. To summarize: The country consists of Tertiary eruptives which show a characteristic phenomenon, in that the earlier eruptives consisted in more basic andesites followed by a series gradually becoming more acidic, culminating in basalts.

The cross fracture referred to intersects the main vein at an angle of 50°. The former dips 70° to the west and the latter 70° to the east, the line of contact evidently descending about 50° from south to north. This fracture produced 385 tons of shipping ore of a net smelter return of over \$311,000. Together with this there had been extracted, to September last, approximately 12,000 tons of an average assay of \$41 per ton. My sampling of the face most remote from the junction was approximately \$70 per ton over 18 ft. The value of such a discovery requires no emphasis.

Mines of more or less similarity geologically to this should, in my opinion, be thoroughly prospected on either

side of the master vein or main component of production, as the case may be. Under such conditions horizontal drilling is invaluable. It is both faster and cheaper than cross-cutting. In replacement deposits like Goldfield, Nevada, and Kalgoorlie, Australia, it also affords valuable data on the widths, in respective parts, throughout a mine. In such deposits, where defining walls are practically non-existent in the earlier stages of development, it is generally more expedient to explore for new ore-shoots than to attempt to block out tonnage under the definite conditions as understood by the mining profession, which, in a deposit of this class, is expensive, and, in many cases, financially prohibitive. Horizontal drilling will, therefore, afford valuable data as to probable production and prevent overlooking valuable cross-fractures.

Like most other departures in mining, a policy of horizontal drilling will open the question of costs. The necessity of getting maximum results is a concurrent phase. Data resulting from a large number of misplaced drill-holes will cost more and afford less information, if any, than a moderate number placed by an engineer who is familiar with the particular conditions. Each case will afford its own particular data. General statements respecting policy in laying out a horizontal program are impossible beyond that ore-bearing cross fractures, if existing, may be more prevalent on the one side of the developed vein than on the other. In this respect, I quote from my report on the property referred to. The main vein, which owes its origin to extensive plane shearing, is referred to as the San Francisco and the cross-fracture as the Esperanza.

"The sampling of the San Francisco vein and that of the Esperanza conclusively proves what may be regarded as an interesting phenomenon, inasmuch as the major deposits are invariably found on the foot-wall of the San Francisco vein and on the hanging wall of the Esperanza. My experience, in similar deposits, is that when valuable minerals show an affinity for either the hanging or foot-wall, in the case of parallel veins the same wall will be the more productive in both cases. The deposits under review are, therefore, an exception to this experience, the only thing in common being that in both cases the greater content is found to the west. It, therefore, seems evident that the cause for this selective characteristic must be in the greater reactive properties of the country to the west of the deposit to that of the east. In my judgment the horizontal diamond-drilling recommended should be extended over the San Francisco vein in a somewhat general manner throughout the workings, but the holes should be to the west rather than to the east. The Esperanza vein was evidently a minor fracture, to relieve local strain, incidental to the profound plane fracturing which constitutes the San Francisco deposit, and it is quite possible there may be others that either have or may be missed by exploration work confined to the San Francisco vein. It is also possible that had the Esperanza fracture occurred to the east instead of the west it might not have been so prolific in metallic content."

The subject of why the fracture vein was so abnormally rich is a broad one and entitled to more space than can be here afforded. A theory that it was a blind cavity, deficient in free exit of mineral solutions, causing thereby partial stagnation, is, in my judgment, attractive. Stagnation, under some circumstances, would probably result in a localization and excess of precipitated sulphides. The reactive character of the country rock or its metasomatic attractions at this particular place might also have had a simultaneous effect. The conditions, at all events, are somewhat different from those influencing enrichments in intersecting veins of the true fissure type that depend on direct precipitation and exhibit the characteristic defining walls and possible banded structure. Here the meeting of alkaline sulphides with metallic sulphides or sulphates arising from different sources, and precipitating through cooling or reaction is more feasible. This, together with acute changes in temperature and neutralization, seems, in the latter class, to be the more reasonable explanation of enrichment.

Making Mine Models

The Editor:

Sir—As comparatively few mine models are made for mine use, it is interesting to note when one is made for that purpose, and with what success. One made some time ago by myself for the Poderosa Mining Co., Ltd., Collahuasi, Chile, is not of the more elaborate type, on account of the difficulty in obtaining the proper materials, but has served its purpose well, and the idea is an excellent one for any mine: especially if native labor is employed in the capacities of shift bosses or foremen. Most natives of South America cannot read a map, no matter how well prepared. Here the model serves to give perspective, and

A CONVENIENT MINE MODEL.

avoids confusion of levels. It gives them the correct idea of the trend of the orebodies, the dip, strike, and faults, besides educating them to be able to understand a map when they see it afterward.

This particular model is made of sheets of glass, horizontally placed for each level, and supported by brass rods along all sides, with beaten copper straps running around the rods, and extending over the glass about three-eighths of an inch both above and below. This forms a firm support for the glasses. The rods are held in a wooden frame, made after the style of old mission furniture. The whole model can be taken apart in five minutes, by sliding out the glasses at one end, then pulling the pegs of the frame. The top glass is set into the wooden frame in the same manner as the top of a show-case. All levels are shown in black, except where ore-shoots occur, which are shown in green. The top glass contains the coördinates, so that any place can be readily located by its block number and letter, besides the claim lines, title, etc. The scale of the model is 1 to 600; it is 4 ft. 3 in. long, 1 ft. 3 in. wide, and 1 ft. 10 in. high, space being left at the bottom for additional levels as they are opened. The paints used for the work were ordinary artist's oil paints, mixed with Japan size and turpentine to make them flow easily from an ordinary draftsman's pen, and still dry quickly.

C. L. SEVERY.

Collahuasi, Chile, January 12.

A Critic Criticized

The Editor:

Sir—It is not good form for an author to complain of the critic who may review his efforts, and I would not do so but that the reviewer of my book on 'Stamp Milling' in your journal has done me an injustice by misquoting. At the end of the second paragraph he quotes me as writing on page 12: "although the latter factor is influenced by the interior and shape of the mortar", leaving out the word "area" after "interior." He complains that many of the sentences are involved, and no doubt they would be to him if he took equal pains to understand them as he has the one above quoted.

ALGERSON DEL MAR.

South Pasadena, February 20.

[The misquotation referred to was due to a typographical error which unfortunately escaped detection, the more easily since the sentence was quoted as an example of faulty writing. No blame therefore should attach to the reviewer, who quoted the sentence exactly as given in the original text.—EDITOR.]

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

SIERRA NEVADA is a Spanish term, signifying 'snow-clad range.'

BOLIVIANITE is a soft lead-gray mineral, resembling stibnite. According to T. Richter, it is an antimonial silver sulphide, containing 8.5% of silver.

THE Amazon river carries annually to the ocean 618,000,000 metric tons of solution and sediment, and its turbidity can be observed in the ocean waters over 100 miles from the land.

RUBBER packing can be prevented from blowing out by cutting pieces of ordinary wire window screen the size of the packing and placing on each side of it. The wire beds itself into the soft packing and holds it in position.

PATENTING a millsite does not involve meeting any special conditions. Those attached to a lode claim may be entered with the lode claim or subsequently; they may even be located after the lode claim is patented. While no \$500 expenditure is required upon a millsite claim, those attached to a lode claim require to be used for some mining and milling purpose in connection with the lode claim, and those unattached to the lode claim, to have an actual reduction works upon them.

DRILLING holes for the foundation bolts of a Cornish pump was done at the Talisman, Karangahake, New Zealand, with a $3\frac{1}{8}$ -in. piston drill weighing 300 lb., making with ordinary drill steel four hundred $5\frac{1}{2}$ -in. strokes per minute with air at 80-lb. pressure. These bolts were 6 in. diam. Hexagonal drill steel 2 in. diam. was used. The starting bit was $6\frac{5}{8}$ in. diam. The finishing drill was 6 in. diam., 7 ft. long, and weighed 84 lb. The drilling was done at the rate of 1 ft. per hour in hard andesite.

ACTUAL settlers, residents, individual miners, and prospectors for minerals, not associations or corporations, may take timber from the public lands in Alaska for firewood, fencing, buildings, mining, prospecting, or other domestic purposes, without charge and without application or previous permit, the amount not to exceed a stumpage value of \$50 in any one calendar year. No timber may be sold, but an agent may be employed to cut it. Application to purchase timber to be cut for use in Alaska, but not for export, may be made to the receiver of the local land office for the district, to be acted upon similar to applications to cut timber in the United States.

FIRST-AID packets are issued by the sanitary department of the Panama canal, to be placed on all locomotives, steam-shovels, dredges, cranes, and boats of the Commission and the Panama railroad. Each packet is of the type provided for knapsacks in the United States army, and contains, within a waterproof wrapper, 2 compresses of antiseptic gauze, 2 small bandages of antiseptic gauze, 2 safety pins, sterilized, and a triangular bandage by means of which a compress may be held in place on the head or any portion of the trunk or limbs. The weight of the packet is a few ounces and its dimensions are $1\frac{1}{2}$ by $2\frac{1}{2}$ by 4 in., making it pocket-size.

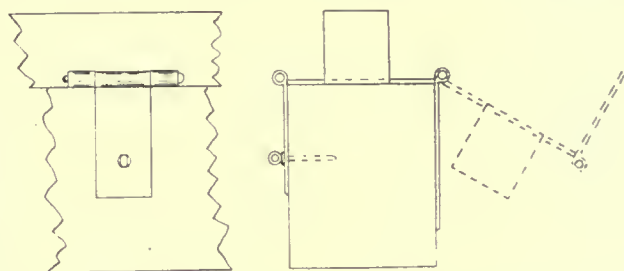

WASTE of natural gas is stated by the United States Geological Survey to be rapidly decreasing. The problem of conserving the natural-gas supply may be considered as having been satisfactorily solved in Pennsylvania, throughout the Appalachian, and the Lima-Indiana fields, and in Kansas. The greatest waste is in Oklahoma and in the Caddo field of Louisiana, owing in Oklahoma to

probable looseness in enforcement of the laws and in Louisiana to lack of a market. It is noteworthy that one of the two wild wells in Louisiana that have been sensational examples of waste has been successfully closed and the gas thus conserved for future use.

WATER-POWER sites have been withdrawn from entry by executive order, and of these, during January, 7252 acres previously withdrawn were, on further examination, restored to entry as having no value for the development of power. The original withdrawals of power-site lands, as recommended by the engineers of the U. S. Geological Survey, are invariably made as small as possible, but where more detailed field examination shows that they can be further cut down without endangering the interests of the public such excess areas are immediately restored to the public domain. Thus, of the nearly 2,000,000 acres which have been withdrawn during the past four years for power sites, 184,383 acres have been so restored.

HUNGARIAN riffles of the angle-iron type are considered by many as the most effective for gold working. These consist of a series of angle-irons spaced $2\frac{1}{2}$ -in. centre, with the horizontal leg placed so that it points downstream. The water passing over the riffles forms an eddy under the projecting leg, which protects the quicksilver and facilitates the catching of the gold. The riffle frames are set with the riffles across the current and are sometimes alternated with plain iron bar riffle frames set in the direction of the flow. Quicksilver is usually fed at regular intervals into the top of the sluice. The small quantities of quicksilver in the sluices and the break in the current, caused by the eddy of the riffles, help to secure amalgamation.

CHANGING cages is not easily accomplished unless there is some convenient method of removing the guides at the top of the shaft. Usually one length of guide is fastened by bolts with countersunk heads, and it is necessary

to unscrew these bolts in order to take out the guide. A quicker way is to have the guide on one side hinged so that by pulling out a pin it can be swung out of the way. A convenient arrangement of this sort is illustrated in the accompanying figure.

CAUSES for one explosive being safer than another in the presence of explosive mixtures of gas or coal dust have been investigated during the past few years. The many thousands of lives lost in coal-mine disasters have shown the necessity for such investigations, and have stimulated to a marked extent researches in regard to the preparation of explosives suitable for use in coal mining. It has been found that every known explosive, if fired in a sufficiently large charge, will cause the ignition of an explosive gas mixture, but explosives have been found to differ widely in regard to the amount that can be fired without causing such ignition. Ordinary black blasting powder, for example, will cause the ignition of explosive gas mixtures very readily, as little as 25 gm. (somewhat less than an ounce) invariably serving to bring about this result. Certain other explosives, in quantities as great as 1000 gm. ($2\frac{1}{5}$ lb.), after repeated trials, under conditions exactly similar to those used in testing black powder, have invariably failed to cause ignition of the explosive gas mixtures.

Special Correspondence

MANILA, P. I.

MINERAL INDUSTRY PROSPERING.—DREDGING RESULTS.—
THE COAL INDUSTRY.—BLACK SAND IN THE PHILIPPINES.—OIL AND ASPHALTUM.

The whole mining industry in the Philippines, which has suffered from so many setbacks in the past, has been given a substantial boost in the past few weeks by the promising returns from the first clean-ups of the Colorado mill on the Island of Masbate. This is a 20-stamp Traylor mill which was erected under the superintendence of C. M. Eye. If the present returns are kept up and are increased, as there is every reason to expect that they will be, Masbate will soon lead the other districts. Preparations are being made to install a mill on the Syndicate property (Old Eastern Mining Co.), where a respectable orebody has been uncovered by recent development work. In the Paracale district, materials for the New York Engineering Co. dredge, to be placed on the Gumaus river for the Philippine Exploration Co., are arriving on the ground. The consolidation of all the interests on the Paracale river has been effected, and a large part of that ground is now controlled by a company headed by Mr. McWhae, a prominent mining man of Australia.

The Philippines dredge on the Malaguit river is digging

HEADWATERS MILL.

in good ground and is making good headway. New machinery has been ordered for the old Paracale dredge, for which a pontoon has been completed. There is no operation on the quartz properties in this district, only some assessment and development work. On the Navotas group, especially, from which some high-grade samples have been assayed by the Division of Mines, good progress is being made. Operations in the Benguet district remain at a standstill. The Headwaters company has shut down, and the well known Benguet Consolidated Co. mill on the lower Antimok river was put completely out of commission during the past typhoon season.

Plans for a consolidation of all the properties on the Lower Antimok have not as yet materialized, for the reason that capital, which was expected to finance the undertaking, has not yet been forthcoming from the China coast, due to the financial stringency as a result of the revolution. Recent work and the washing out of some of the streams by the typhoon has shown up more veins and larger orebodies than were before known. It is beyond question in the minds of those who have seen the ground that large and profitable orebodies exist in this district and that some day the Philippine Islands will take high rank among the gold producers of the world.

Some excellent alluvial ground has been discovered on the east coast of Luzon, almost due east from Manila. An Australian company has promised to have a dredge at work on the Umira river in 1913. Above the dredging ground, another company has planned to install hydraulic machinery. Black sand from some of this ground, when tested by the Division of Mines, by grinding in a tube-mill, and cyaniding, showed that after the free gold has been removed

high extraction can be obtained. The Division of Mines is now investigating black sand from all over the Philippines, as this promises good returns when the right process has been found.

The coal industry, which came near to succumbing completely a year ago, has been resuscitated by the timely assistance of the Government, and from the last reports, the East Batan coal mine is progressing as satisfactorily as can be expected, considering the quality of the coal and the circumstances under which the operations must necessarily be carried on.

No headway has been made in the development of the Tayabas oilfield, and it is not likely that any material advances will be made until the present methods there have been radically changed. Warren D. Smith, the chief of the Division of Mines, while on leave in the United States, will spend a month in study in one of the California oilfields in preparation for projected work in the Philippine fields. The recent discovery of asphaltum in the mountains of Rizal province of Luzon, a two-days' walk from Manila, promises to be of great importance to the Islands.

NEW YORK

DIVIDENDS, DECLARED AND PROSPECTIVE.—INCREASED METAL DEMAND.—LITIGATION.—SAN TOY AFFAIRS.—CHANCE FOR SPECULATION IN SILVER.

While there has been no noticeable improvement in Wall Street conditions during the past week, there are some features in copper that are being pointed to with a measure of pride, as reflecting the increase in prices in the metal market.

Calumet & Hecla has declared a quarterly dividend of \$8 per share, as against \$6 paid three months ago and one year ago. The Miami Copper Co. has made a semi-official announcement, through J. Parke Clanning, that the initial dividend of the Miami is to be 50¢ per share, and that in all probability it will be declared as a quarterly payment. Miami will be the first of the new Arizona porphyries to enter the ranks of the dividend payers, although it is expected that Chino, in New Mexico, will announce a dividend some time during the spring, as will also the Ray Consolidated. Miami has started the sixth unit of its concentrator, and expects to produce during the current month 3,000,000 lb. of copper. January earnings were at the rate of \$150,000 net, which would be equivalent to something better than \$2 per share per year. It is stated that Miami sold some copper at 14½¢ recently, getting the top of the market on the present move. The recent dividend paid by the Bonanza group of mines at Kennecott, Alaska, amounted to \$1,000,000. The company is capitalized at \$2,500,000, but has expended some \$23,000,000 in developing the mines and building the Copper River railroad. The railroad is said to be now on a basis where it pays its operating expenses, but it will be a long time before it will return any dividend out of its own earnings on the amount invested in it. The Bonanza mines represent one of the largest high-grade copper deposits recently developed. Engineers estimate that there is about 100,000 tons of 65% ore now ready for extraction; shipments up to the present time total about 16,000 tons. While the railroad was necessary for the operation of the mines, the real return upon this investment was and is expected to come from the opening of the tributary territory, and while Morgan & Co., Kuhn, Loeb & Co., and the Guggenheims, constituting what is known as the Morgan-Guggenheim syndicate, are apparently receiving a large return in taking down a dividend of \$1,000,000, the fact remains that this syndicate has a large investment upon which it will never reap its expected profit until other outside capital goes into Alaska to develop its resources. Notwithstanding Alaska's much-talked-of immense coalfields, the Copper River railroad operates its engines with fuel oil, shipped in by tank steamer from California.

Reports from metal brokers in London tell of an increased demand, and it is expected that the amount of

metal exported will be the feature of the coming report of the Producers' Association. The world's visible supply is estimated at a much lower figure than at any time during the past two years. There has been no change in the policy of ignoring the fact that a large percentage of this copper has been purchased by various governments in preparation for possible coming hostilities, and it is possibly owing to this fact, and the belief that commercial requirements have not accounted for the shrinkage in accumulated stocks, that there are stories from time to time of hidden supplies of copper on the Continent that are so held as not to be taken into account statistically. One important financial New York paper, while ignoring the purpose of the market move, states that "the heavy shipments during the last two months made to Havre make it evident that 15,000,000 tons has gone into warehouse which has not been taken account of statistically. The metal has not gone into consumption, American shipments into France being largely in excess of the consumptive capacity of the country. There is reason to believe that similar transfers were also made to Germany and Holland, so that European statistics of stocks are either fragmentary or unreliable." In any event, it is quite evident that there is a much stronger combination existing in copper metal than ever before, and that the recent bull pool operations have been backed by enormous capital. If there has been a corner successfully engineered in copper, it will be well for the public, as well as the operators, to bear in mind the fact that with sufficient capital there is no great degree of difficulty in acquiring control of a commodity. The real test comes when the unloading begins, or, as the market phrase goes, "when the attempt is made to bury the corpse."

The various defendants in the suit brought by the United Copper Securities Co., the organization formed by Arthur P. Heinze, to rehabilitate the United Copper Co., acknowledge themselves to be as much in the dark as any part of the public, in regard to the relief suit by the recently instituted litigation. The suit would appear to be brought rather late in the day, as several of the defendants named, both corporate and individual, have alike gone the way of all things earthly.

The suit of the Government against George Graham Rice and others is apparently developing into something of an endurance contest. It is now in its fifth month, and a well known mining engineer, who was called upon to testify, commenting upon the length of the trial, stated that they had really but just begun. The case bids fair to furnish ground for some of the caustic criticisms made regarding the delays in our criminal procedure.

The management of the San Toy Mining Co. has issued a reply to the charges made by the committee of local stockholders regarding the Quince de Mayo lease, defending the action of D. B. Gillies, general manager for the company, on the ground that the directors did not care to take the risk in developing adjacent territory, but were willing to allow Mr. Gillies to do so, as any favorable developments would be of great benefit to the San Toy company. The use of the San Toy shaft and equipment was not given without compensation, but it was understood that if any ore were produced from the lease, the company should hoist the ore and receive a reasonable charge for so doing. The San Toy operations for January show a deficit of \$4260, the mine being shut down during two weeks, on account of a strike among the laborers, and no ore was shipped during February on account of the discontinuance of service by the National Railways of Mexico south of Chihuahua.

Looking on the one hand at the stagnation of business on the New York Stock Exchange, and on the other hand at the results which have been accomplished in the copper-metal market within the past ninety days, and recalling also the active speculation that existed at one time upon the old Gold Exchange, some of the restless spirits in Wall Street have suggested that the position of silver presents some possibilities that might induce the public to indulge in speculation. Just at present the public has its head so pointed in the other direction from Wall Street, and is

so apparently deaf to all inducements, that the Street itself would take a chance in making a market in dynamite, if that would bring any customers into the market-place. As to silver, it is argued that China regenerated will soon go on a silver basis with greatly enlarged needs; that India must soon buy silver for Government coinage, and that legitimate conditions are bound to force silver and lead to higher levels than have prevailed for some years. The so-called Indian pool is estimated to hold some 20,000,000 oz. of silver. As this is less than 10% of the world's annual production, and as the pool's operations have resulted in an advance of something like 8c., it is argued that a strong combination of American capital in America could make the pool pay considerably higher prices, in order to maintain its position. The operators in India, and the dealers in bullion in London, have been somewhat antagonistic, but as it has apparently been rather easy for the Indian pool to accomplish what has been done, it is believed that American capitalists could make themselves a decided factor if they entered the field. Details would have to be worked out that would permit certificates being issued against bullion in storage, and it is through the trading on these certificates that the public would be invited to take part in the operation. It is extremely doubtful whether anything more than talk will be developed along this line, but it is true that market operators would vociferously welcome anything that would create general interest and some market activity.

JARBIDGE, NEVADA

DEVELOPMENT OF ALPHA GROUP.—PROSPECTING THE FLAXIE.

—DEVELOPING DEEPER LEVELS.—THE PAVLAK AND FLETCHER MILLS.

Chicago capitalists have taken over the Alpha group and have a force of men at work developing. Very little actual development work has been done on this vein, although small open-cuts have been made for 700 ft. along the surface and showing a vein 2 to 7 ft. wide. Average assays are \$10 to \$40 per ton, with portions of the quartz showing free gold and yielding a long string of colors in the pan.

Across Bourne gulch, to the north from the Alpha, the New York people who are prospecting the Flaxie vein are meeting with excellent results; at a depth of 75 ft. from the surface a drift has been run along the vein in a continuous ore-shoot for 125 ft. This vein has a width of 4 to 6 ft., and numerous samples assay \$40 to \$152 per ton. At the face is 8 in. of quartz that runs nearly \$600 per ton; this is considered to be one of the best bodies of ore opened, and will crowd either the Bluster or Success for first place in the district.

The adit on the Jarbidge Gold Co.'s property, adjoining the Flaxie, has entered the Flaxie vein, which here is about 20 ft. wide and somewhat broken, being very near the surface. The average content is not so great as in the Flaxie workings, but on the whole the future promise of this property can be considered very bright. About a quarter of a mile to the northwest, on the Mother Lode claim, an adit is being run to intersect the Flaxie vein. And on the Cabin claim, near the river, a long adit is projected to cut the Flaxie vein at depth. The Success is pushing work on its four adit-levels, with every indication that the three ore-shoots on the upper levels persist, although the veins are somewhat faulted and irregular. George Wingfield has sent in a new superintendent to take charge; he has made another payment on the Success. Development on the Bluster on the adit or 300-ft. level is opening another ore-shoot to the south of the shaft. Mr. Wingfield is examining and sampling the Pavlak mine.

The expected shut-down of both the Pavlak and Fletcher mills has occurred, not from any lack of ore nor from any lack of gold content, but from the usual troubles that overtake a mine or mining company, no matter how good the mine may be, when inexperienced men are in charge. Capital finally becomes tired of paying for experience, and work is at a standstill until the bills are paid, a re-organization effected, and more money raised to remodel

the mill so that it will not only pulverize the ore, but save the mineral. The Pavlak mill was built on much too large a scale for the size of the orebodies, and its crushing and pulverizing equipment is practically no good. The Fletcher mill handled a little more ore since remodeling, but much too large a percentage of the mineral content was lost. As these errors are only such as can be easily overcome, it is expected that both of these mines will soon be running again and that the experience thus bought will prove of benefit to the other mines now developing. The ores at Jarbidge are not high grade, although they should pay good profits when properly treated; veins of 3 to 10 ft. in width are good workable size, and with ore of from \$10 to \$20 per ton, there is no reason why they should not be worked at a good profit; but a saving of over 50% and a running time in mill of over 40% are certainly necessary. Considerable work has been done this winter to the south of Bonanza ridge, along Gorge gulch, Snowslide gulch, and Dry gulch, and while no startling discoveries have been made, there are indications that lead to the belief that they will be heard from during the coming season.

SILVERTON, COLORADO

FRISCO TUNNEL COMPANY TO BUILD MILL.—SUNNYSIDE OPERATING NEW ZINC PLANT.—KITTIMAC DEVELOPMENT.—NEW IOWA TIGER LEASE SHIPS EXCELLENT CONCENTRATE.—GOLD KING SUB-LESSEES DEVELOPING.

The San Juan district is experiencing a very mild winter and the snowfall has been exceedingly light. All necessary trails have been kept open and there has been no delay in receiving supplies and shipping ore. Charles Gagner, manager of the Frisco Tunnel Co., operator of the Bagley adit at Animas Forks, has returned from Pittsburg and announces that all financial arrangements have been completed and that work will begin on a reduction mill at an early date. It is rumored that Otto Mears has secured a bond and lease on the Gold Prince mine and mill, but no announcement of future plans has yet been made. All other properties at Animas Forks are idle, but it is probable that the Sound Democrat, Frank Hough, and Columbus will be active this season.

At Eureka the Sunnyside maintains its usual production and has started its new zinc plant, from which much is expected. The plant is equipped with electric separators and the company hopes to raise the percentage of zinc in the zinc concentrate above 40, which is at present the lowest percentage that can be shipped from this district at a profit. The results obtained in the new plant are not yet available. The Kittimac is being developed and John Joyce, the manager, announces that mine and mill will be in operation this season. The mill will be thoroughly overhauled and a cyanide plant added, and Mr. Joyce expects excellent results from the new milling methods which he plans to introduce. The Silver Lake is running two shifts and employs about one hundred men at mine and mill. The ore is of fair grade and the property is giving good returns under the new management. The Iowa Tiger Mining Co., successor of the Iowa Tiger Leasing Co., has shipped thirty cars of concentrate during February. This concentrate is better grade than any shipped for many months and nets the lessees \$800 per car of 20 tons. Most of the crude is coming from the Melville vein, which previous lessees refused to operate, regarding it of no value. Forty sub-lessees are working in the Gold King mine, and report large tonnages of ore available for the mill, which will be started in April.

The Ledge Consolidated closed down February 10, without meeting its pay-roll or other obligations. The available ore in sight had steadily decreased for several months prior to the shut-down, and the company had made little effort to develop new ore, so that the shut-down was not unexpected. The company has about \$8000 on hand to cover accounts amounting to \$30,000, so that the miners and the local merchants are left, as usual, 'holding the sack.' The company had a bond and lease on the old Silver Ledge mine at Chattanooga, and the stockholders have invested about \$150,000

in an effort to rehabilitate this old property. As stated in a previous article, the company's affairs have been woefully mismanaged from the start, and the board of directors, residents of Chicago mostly, have interfered with and handicapped the local managers so that success was almost impossible. The company has been directed by men ignorant of mining and unwilling to leave the local direction in the hands of competent men. During the two years and six months these men have directed its affairs the company has boasted seven general managers, eight mine superintendents, and three mill superintendents. The directors are at present negotiating with R. W. Hollis, trustee for the Ledge M. & M. Co. creditors, for an extension of time on property payments and more liberal terms in general, but success under the present board seems hardly possible, no matter what terms are granted. The Congress lessees report good progress, and the machines are at present in a hard iron pyrite formation, which makes considerable water, and which may be the pyritic casing which has always enclosed the enargite ore-shoot at the Congress.

KALGOORLIE, WESTERN AUSTRALIA

A CAMEL-BACK SURVEY.—DEEP-LEVEL EXPLORATION IN THE HORSE-SHOE.—NOTES OF THE DISTRICT.—PRODUCTION RECORDS FOR DECEMBER AND THE YEAR.

The Mines Department has decided to keep one of the Geological Survey parties equipped with camels, employed upon flying surveys of those areas remote from settlement,

TYPICAL SURFACE PLANT ON THE GOLDEN MILE.

with the object of indicating, for the guidance of prospectors, any promising belts of country. The party will also look after water-supplies for these areas. A mill is being erected at Mount Egerton, near Peak Hill. The Department has not decided to build mills at Bamboo creek and Woodgina, in the Pilbarra field; and at Weston's, near Southern Cross. These fields require a little more development yet. Mention has been made of the Associated Northern buying for \$110,000 the Gimlet South Extended, at Ora Banda, near Kalgoorlie. During the option 3190 ft. of exploratory work was done at three levels. At present, they are stripping the shaft and getting ready for the mill. This is to cost \$125,000. The ore reserves are given as 159,000 tons, worth \$950,000. This is all above the sulphide zone.

Last year the Horse-Shoe, boring from the 2800-ft. level of the Great Boulder, cut the boundary lode of its property, it being 18 ft. wide, worth \$25 per ton. As the former's main shaft was down only some 2000 ft., it would mean a long time before this ore was reached by sinking and cross-cutting; so an arrangement was made with the Boulder people to cross-cut from their main and Edwards shafts at the 2650 and 2800-ft. levels. In the meantime the Horse-Shoe shaft would be sunk to these levels, and cross-cuts driven, so that early in 1913 it is expected to haul this ore to the mill. The following cables on this subject may be interesting. (1) West cross-cut of south drift, at 2800-ft. level of Boulder main shaft, cut No. 4 lode a few feet from north boundary, and 16 ft. from east boundary. It is well defined, but width and value not determined. (On the north is the Ivanhoe and east the Boulder.) (2) Lode is disturbed by a slide. Disturbed section extends to present face of cross-cut 35 ft. from east boundary. Boring for 4 ft. from face of cross-cut assays give \$41.20 per ton. (The Horse-Shoe and Ivanhoe lodes are frequently disturbed by slides.) (3) Through the lode, with \$33 over 6-ft. width. Well defined, and showing telluride and free gold. This is an important result, and work at Edwards' shaft is awaited with interest.

The Ivanhoe main shaft is now down 2600 ft. in country. From the Associated, Perseverance, Lake View & Star, and Kalgurli there is very little of note to report. The Holman pneumatic stamps are now at work on the Mountain Queen, near Southern Cross, and may furnish some interesting data from this new type of pulverizer. At the Hainault, a Richards classifier has been installed and is now under trial. The gold yield for December was valued at \$2,470,000, making \$29,110,000 for 1911, against \$31,060,000 for 1910, and a total, to date, of \$524,340,000.

The Perth mint received bullion worth \$2,400,000 in December, and for the year past a total of \$25,710,000; while the total issue of sovereigns and half-sovereigns was valued at \$25,655,000. Dividends for the year totaled \$4,110,000. The yield during December from the principal mines was as below:

Property.	Tonnage.	Gross Value.	Profit.
Associated	10,252	\$ 59,500	\$ 4,200*
Associated Northern	1,263	11,000
Burbanks Main Lode	1,394	17,500
Golden Horse-Shoe	22,221	137,000	1,400
Golden Ridge	2,705	26,300	8,700
Great Boulder Perseverance	19,666	102,200	6,200
Great Boulder Proprietary	16,908	242,500	144,800
Great Fingall	6,027	59,000	11,400
Hainault	5,048	35,300	2,000
Ivanhoe	18,641	200,000	90,000
Kalgurli	10,040	104,000	45,000
Lake View & Star	18,009	104,500	18,300
Oroya Black Range	4,580	45,800	17,200
Oroyo Links	10,510	60,600	12,100
Sons of Gwalia	14,020	129,300	48,500
Sons of Gwalia South	2,141	13,500	3,600
South Kalgurli	9,620	60,000	11,000

*Loss.

LONDON

RECORD OF SOUTH CROFTY FOR YEAR.—EAST POOL PROFITS.
—RESULTS OF WHEAL KITTY & PENHALLS.—REPORTS
FOR THE YEAR.

At this time of year the position of the tin-mining companies in Cornwall come up for review. Perhaps South Crofty is the company which may claim the precedence in receiving notice in this column. The results for the year 1911 are decidedly gratifying. Every item of the accounts shows an advance: the total production of tin, tungsten, and arsenic, the yield per ton of all three products, and the income and profit. Naturally the high price of tin has been in the company's favor, but, on the other hand, the prices realized for tungsten and arsenic have been slightly lower. The mill treated 63,882 tons of ore during the year, and the recovery was 677 tons of black tin which

sold for £76,587; 148 tons of tungsten concentrate selling for £14,717, and 1008 tons of arsenic products selling for £9518. The total receipts were £100,822, and the receipts per ton 31s. 6d. The yield per ton of ore was 23.76 lb. black tin, 5.22 lb. wolfram, and 35.36 lb. arsenic products. As compared with 1910, the yield showed an increase of 47 tons black tin, 22 tons tungsten, and 272 tons of arsenic products, and the receipts per ton of ore treated, 6s. The profit for 1911, after allowing for depreciation and all other expenses, was £31,981, out of which £17,500 was distributed as dividend, being at the rate of 35% on the nominal capital, and £10,000 was placed to reserve. This dividend of 35% is of course a handsome one, but it must be remembered that when the present company was started five years ago outsiders paid £4 each for the £1 shares, so that their return is only 8¾% on their money.

One of the old mines, East Pool, that did well formerly, has been in rather low water for the past four years, owing to the fall in the grade of the ore. It is still worked on the cost-book system, and in consequence has been short of capital, and the underground development has been greatly neglected. It is pleasant to be able to report that the accounts for the three months ended December 31 last showed a profit of £749, which enabled the adverse balance of the previous quarter, amounting to £402, to be wiped out, and £347 to be carried forward. This is the first time since 1907 that the company has made a profit. There was a good deal of talk at the shareholders' meeting about dividends in the near future, but any division of profit would be absolute folly, seeing how the development of the property has been neglected for many years past. All the money that is likely to be made for the next few quarters should be devoted to vigorously developing the mine, so as to raise the grade and enable the management to face with equanimity a fall in the price of tin. For the past quarter, the average recovery was 19.25 lb. of tin and tungsten per ton, and the price received for the black tin averaged close to £114 per ton. The development for the past quarter was only 276 ft., and the tonnage milled 17,337, so that the footage was only 1 foot for every 62 tons milled. The receipts were £17,317, or 19s. 11d. per ton milled, while the costs were £16,568, or 19s. 1d. per ton. It is to be hoped that the directors will take courage to turn the company into one of limited liability, and raise adequate funds for conducting development on a proper scale. The treatment plant is thoroughly up to date, containing Holman air-cushion stamps, tube-mills, and magnetic separators. Those who are particularly interested in the subject will find a flow-sheet of the mill given in *The Mining Magazine* for February. The directors have recently gone so far toward publicizing the company as to appoint an outside accountant as auditor and adviser. It seems late in the day to have to record this step.

I reported a few months ago that the Wheal Kitty & Penhalls, an admirably managed little mine in the St. Agnes district, had unfortunately got into poor ground. This fact is reflected in the accounts for the latter half of 1911. After having shown continuous profits since its formation in 1907, this company has had now to report a small loss. The cause is obvious from the report, for it appears that the yield has dropped from 28 lb. per ton for the first half of 1911 to 19.9 lb. for the six months under review. Fortunately, the price of black tin was well maintained, or the position would be serious. The southern section of the Stamps lode has been a great disappointment. When intersected in the south cross-cut from Sara's shaft last July, the lode had a most promising appearance; so much so, that at the shareholders' meeting last August the speakers permitted themselves to paint the discovery in glowing colors. However, these ups and downs are to be expected in the St. Agnes district. It is satisfactory to see that the recovery is again on the up-grade, for at the last ticketing seven tons was offered for sale, which is the best fortnightly return since June last. During July to December 1911, 8384 tons was treated, with recovery of 19.9 lb., worth 20s. 3d. per ton, at a working cost of 21s. 2d.

General Mining News

ALASKA

COPPER RIVER

The McKinley Lake M. Co. has intersected a vein of ore of which five tons milled about \$14 per ton. The company has about 450 ft. of development work. The Lucky Strike company, which has completed about 440 ft. of development work, has intersected a valuable vein 18 in. to 4 ft. wide.

The Northern Development Co., coöperating with the Copper River & Northwestern railroad, will operate motor cars across the surface of Kennicott glacier for transporting copper ore. Construction of the road will start soon.

CORDOVA

It is reported that a large deposit of high-grade einna-

pany, through M. M. Reese, is negotiating the purchase of a 20-stamp mill now lying idle near Douglas.

THE TANANA

W. B. Mallison has purchased a 50-hp. boiler for his claim on 4 Below Goldstream, says a report from Fox City. He intends to do open-cut work. McGillivray & Fisher, lessees on the Cleary extension of the Newsboy vein, have ordered a 5-stamp mill from Brumbaugh & Hamilton, states a Fairbanks report. It is believed the mill will be in operation by April 1. A. J. Smythe recently discovered unusually rich ore near the Jesson property at the head of Chatham creek, near Chatanika.

ARIZONA

COCHISE COUNTY

The Commonwealth M. & M. Co. is making preparations for the construction of a 300-ton mill and cyanide plant at Pearce. It will be built in units, so that it may be

MAP OF ALASKA.

bar ore has been discovered recently between the Kuskokwim and Yukon rivers. An ore-shoot of metaeinna-barite was opened from which assays of 60% einnabar were obtained. It occurs in sandstone and serpentine, with a little limestone. The conditions are favorable for mining. Allen Chester, of Rebel Creek, Nevada, is interested. Samples of the ore will be placed on exhibition at Room 221, National Bank building, San Francisco.

JUNEAU

The Alaska Treadwell G. M. Co., during the month of January, made a production of gold and concentrate valued at \$133,883, with a realizable value of \$132,544. Operating expenses amounted to \$97,463, leaving an operating profit of \$35,081. Construction expenses were \$6939, leaving an estimated net profit of \$28,142. The ore milled yielded \$2.29 per ton. During the month 992 ft. of development work was done.

PRINCE WILLIAM SOUND

It is reported that the vein has been intersected on the Mayfield property, 200 ft. below the surface, after a cross-cut had been driven about 180 ft. The vein at that point is said to be about 12 ft. wide. The Mayfield com-

pany, through M. M. Reese, is negotiating the purchase of a 20-stamp mill now lying idle near Douglas.

At a recent meeting Charles E. Knox was elected president of the company, succeeding A. Y. Smith, and W. B. Alexander was elected secretary-treasurer, succeeding J. H. Snyder.

Advices from Bisbee state that ore assaying as high as 50% copper has been found on the 400-ft. level of the Shattuck mine.

GILA COUNTY

The Miami Copper Co.'s concentrator is now in full operation and is handling 3000 tons of ore per day. It is reported running satisfactorily and making a recovery close to 75%. While some changes will be made, especially in the crushing machinery, yet they will be introduced gradually and without interfering with the mill's operation. The mine is easily furnishing all the ore the mill can handle, and considerable development work is being done. Assembling of machinery in the power-house at the town of Miami continues and should be finished in a few weeks. The ground northeast of the orebody is being explored by churn-drilling, there being one drill in use at present, though another may be added later. At the Live Oak mine the erection of equipment at No. 2 shaft, and the enlargement of this shaft from two to three

compartments, is proceeding rapidly. The churn-drill hole on the Barney group is 1070 ft. deep and in granite-porphry. Another churn-drill was put to work last week near the eastern end of the property near the Live Oak boundary.

GREENLEE COUNTY

The Arizona Celtic Copper Co. has been organized at Clifton, capitalized at \$3,000,000. The incorporators are D. F. Lynch, R. T. O'Donnell, and A. G. Shaw.

YAVAPAI COUNTY

Press rumors state that the Bagdad Copper Co. is planning to build a branch from the Santa Fé railroad to its property, formerly the Lawler copper mines, in the Eureka district. It also is reported that a large reduction plant will be built. The Lake Superior & Nevada M. Co. mill, near Harrington, is to be put in operation soon. The United Gold Mines Co.'s mill will resume operation April 1, according to an announcement by D. J. Sullivan.

James Blanchard is reported to have discovered a 5-ft. vein of rich gold ore on his claim a mile from Turkey, a station on the Bradshaw Mountain railroad. The Gold Cliff M. Co. has acquired the Yarnell mine. W. E. Sharps is at the head of the company, which is planning operation on a large scale. According to S. R. McGarvey, the Yavapai Metals M. Co. has intersected unusually rich ore in a cross-cut from the 250-ft. level.

CALIFORNIA

MARIPOSA COUNTY

(Special Correspondence.)—The Clearing House M. Co., operating the Original mine on the Y. V. railroad, one of the successful mines of Mariposa county, is now installing a power-plant to generate power for operating purposes. The Original mine, according to reports by the company, has an adit 275 ft. long, all in good ore, and above the adit is sufficient ore for a year's run. In the winze, down to where the water could not be handled, is considerable high-grade ore. The power-plant has a 5-drill cross-compound compressor, driven by a 108-hp. turbine. The electric hoist, capable of sinking 1000 ft., is driven by a 150-hp. Westinghouse alternating-current 440-volt generator. This generator is driven by a 230-hp. turbine. Water is diverted from the Merced river by a timber crib dam across the river, to a ditch a quarter of a mile in length and into a flume with a carrying capacity of 6000 miner's inches of water. The total mean efficient head on the turbine is 24 ft. H. A. Kuns is consulting engineer and George W. Egenhoff is superintendent of this property. The company is now considering erecting a 10-stamp mill. Stock of the company is owned principally in Merced.

Merced, March 2.

PLUMAS COUNTY

(Special Correspondence.)—The recently incorporated Grellman M. Co. is completing preparations for working the Colonial mine, on Mill creek. The gravel is mined by the drift method. J. G. Steel is manager. A development company is being organized by Llewellyn A. Morrison, of New York, to operate the Elizabethan group of six quartz claims, near Quincy. Morrison recently bonded the group from C. Bayles for \$70,000. The Spring Garden channel has been intersected in the Brown Bear mine. Driving has been under way for several months. A washing plant is being erected. A. Dennis is manager. An electric hoist has been installed at the Golden Eagle. In the old workings a fair amount of ore is said to be blocked out. The Frankmont M. Co. is extending a 4500-ft. adit into the Home Ticket mine, by way of the Eldorado estate. The work is rapidly nearing completion, and operation at the Home Ticket will commence shortly. W. S. Keith is superintendent. The property is situated in the Last Chance district. The new gravel deposit, about 50 ft. below the Thistle channel, is being opened by an adit. It is reported some of the gravel runs \$40 per cubic yard in gold. About 80 men are employed. R. H. Kingdon is

manager. The Eagle Copper Co., owning a group of developed copper claims near Taylorsville, expects to start smelting this summer. The smelter is nearly completed, and ample ore reserves are available. The company is composed principally of San Francisco people.

Quincy, March 1.

SIERRA COUNTY

(Special Correspondence.)—The drift from the Tightner adit toward the Red Star mine has intersected a vein showing in places a width of 10 ft. It has been opened sufficiently to indicate a length of about 200 ft. Arrangements are being made to open it to greater depth. Since the new owning company, composed of San Francisco, Grass Valley, and Nevada City people, took over the Tightner, a large quantity of ore has been opened. Abe Hall, formerly with the North Star Mines Co., is in charge of operations. It is stated the new plant of machinery for the Sixteen-to-One will be immediately shipped in and erected. The company has been delaying shipment for fear that a storm would render freighting practically impossible. Oakland people are interested. W. J. Smart is manager. The Oasis M. & M. Co. reports the intersection of the long-lost King Solomon vein in the Kenton mine. The lode is said to be 12 ft. wide with a good portion carrying milling ore. Arrangements are under way to repair the small mill and commence crushing early in April, if the water-supply proves sufficient. E. S. Polk is manager. Los Angeles people control the company. An 8-ft. vein has been intersected by the 700-ft. adit at the Red Ledge, at Scott's Flat, on lower Kanaka creek. Arrangements are being made to develop the vein and determine its value. Buffalo, New York, people are back of the development. It is reported a mill will be erected the coming summer to replace the one burned several years ago. J. B. Moulton is superintendent. The Rainbow company has purchased additional machinery and plans have been made for further sinking. L. P. Woodbury is manager. The Croesus mill is treating a good quality of ore. This property continues to be the heaviest producer in the Alleghany district. The Sovereign M. Co. has its mill and cyanide plant in action. The latter is reported to be effecting a saving of 90%. A mile line of flumes has been completed to convey the tailing to a point where the domestic water-supply will not be contaminated. F. O. Richardson is superintendent.

Alleghany, March 2.

The old adit and drifts of the North Fork drift gravel mine have been successfully reopened, after several years of work, by J. F. Stone, general manager for the North Fork M. Co. The inclined adit is 1050 ft. long. The property is near Forest.

TULUMNE COUNTY

(Special Correspondence.)—A new compressor and electric-power apparatus will be installed at the Bonanza mine. Meanwhile operations have ceased, owing to the failure of the pumps to control the water. New cement mortar-blocks for 30 additional stamps are being installed at the Harvard. This will bring the total number of stamps up to 90. The sinking of the shaft 300 ft. deeper has necessitated the temporary laying off of many men. Rich ore has been found at the Imperial. The Dutch mill, strengthened by the addition of twenty stamps, will be running by the first of April. Development work is being done by a San Francisco company upon the Oak Hill and Mitchell mines, in the southwestern part of the county. John Whitney has uncovered the old gravel bed at the Humbug tunnel. Washings give high results per yard and the outlook is most encouraging. Electricity from the Phoenix Lake power-plant is now used at the Black Oak mine. A large 8-drill compressor is in place and the new roller mill and cyanide plant will soon be finished. By improved methods it is expected to save more than 85% of the gold content. The rich shoot of ore, which was found in the 1400 and 1500-ft. levels, is now being sought for in the 1600-ft. level, where a cross-cut is being run. An increased inflow of water at the Springfield T. & D. Co.'s property has made it necessary to remove the boilers from the Ravich mine in order

to install a steam pumping plant. Some difficulty is experienced at the Saratoga M. & D. Co.'s mine, below Springfield, by the filling of the workings with clay which bursts continually from the face of the adit.

Wayland Avery, of San Francisco, has given R. C. Kennedy of San Francisco, A. Wagner of Alameda, and M. Tucker of Tuolumne, an option to purchase the Starr King and Sherman quartz mines. The purchase price is \$16,500, to be paid in installments. The intending purchasers agree to unwater the Starr King mine shaft and to work without interruption, for which \$600 will be deducted from the first payment. A force of men will be put on at the Iron Spring group of mines, where a cross-cut will be driven about 700 ft. A new mill has been ordered and will be installed at once.

Tuolumne, March 4.

COLORADO

CLARE CREEK COUNTY

(Special Correspondence.)—Word was received in Georgetown last Tuesday that the Centennial mine, on Leavenworth mountain, had been sold by David Kennedy to Boston capitalists for \$125,000. It is stated that a 50-ton mill will be constructed and that a new compressor-plant will be purchased. Work has been resumed on the Big Blue property, situated on Saxon mountain. Driving has been started on the Big Blue vein, cut 600 ft. from the portal of the adit. An 8-in. streak of \$30 ore is being followed. A. Santo is manager. The Ontario mine, on Young mountain, is the scene of a rich discovery. A streak of ore 12 in. wide gives assays of 180 oz. silver and 1.10 oz. gold per ton. William Young is manager. The compressor-plant at the Everett mine on Republican mountain will be brought into commission next week. Shipments of 200-oz. silver ore are going out. Otto Shatz is lessee.

Georgetown, March 2.

The Saxon mine, near Georgetown, has been purchased by Poindexter & McDonald of Seattle. It is reported that a development fund amounting to \$30,000 will be provided for operation, which will not be started for a month or two.

OURAY COUNTY

Press reports assert that enough ore has been blocked out in the newly proved ground of the Camp Bird vein to insure a year's reserve in addition to the ore which will be treated at the mill. The bottom of the winze, now being made to conform from the fourth level to the dimensions of the new shaft which is being sunk from the third level, has shown the vein to be nearly vertical, and about five feet wide. The ore is of profitable grade. It is reported that a sample taken from the Muldoon vein by Frank Beech and Robert Long assayed 1700 oz. silver and $4\frac{1}{2}$ oz. gold per ton. The discovery was made on the road connecting the Camp Bird and Revenue mills. The men have a lease on the property.

SAN JUAN COUNTY

A. A. Brown, representing Eastern capital, has secured a bond and lease on the Columbine group, in Maggie gulch. The property is an extension of the Buffalo Boy. Work will be started early in the spring, says a Silverton report.

TELLER COUNTY (CRIPPLE CREEK)

The Golden Cycle M. Co. has paid its regular dividend for March, at a rate of 1c. per share. The \$30,000 required brings the dividend total for the year to \$90,000. The Union Leasing Co., operating the Gold Dollar Con. M. Co.'s Husted shaft on Beacon hill, in February shipped 28 cars of ore, which averaged about \$30 per ton. Arthur Carduff and associates, lessees on the Dead Pine-Crown Point property, during last month shipped 15 cars of milling grade ore. The Puritan G. M. Co. has secured its patent on the Holy Terror claim.

During February the main bore of the Roosevelt drainage adit was driven 209 ft. Only one day was lost. T. R. Countryman, engineer for the project, estimates the flow to be over 10,000 gal. per minute. The washing away

of the weirs has made accurate measurement of the flow impossible. The driving of the adit was in charge of Charles Fuller, superintendent. The Colorado Mines & Investment Co.'s American Eagle mine in February shipped 17 cars of ore averaging about \$60 per ton. The Pride of Cripple Creek shipped 7 cars. The School Section L. Co. during the month shipped 18 cars of ore.

The El Paso mine, Beacon hill, in February shipped 103 cars of ore averaging about \$20 per ton. The Marquette Gold M. Co. is considering reorganization. L. J. A. Cockburn, secretary of the company, has addressed a letter containing a plan of reorganization to the stockholders. The Kitty Lane Gold M. Co., a reorganization of the Gould company, has been incorporated, with a capitalization of \$2,000,000. Matha & Co., holding a lease

EL PASO MINE, CRIPPLE CREEK.

on the Pharmacist mine, Bull hill, recently shipped five cars of ore.

IDAHO

IDAHO COUNTY

The Elk City Con. Mines Co., a Spokane company, is about to erect a Chilean mill on its property, which is situated about six miles from Elk City. The adit is in 200 ft. During development, about 300 tons of ore, reported to assay \$6 per ton, was removed.

KOOTENAI COUNTY

The Palisade M. & M. Co., capitalized at \$1,500,000, has been incorporated. T. W. Schmidt, of Cataldo, is president of the new company, which has a lead-silver mine at the head of Pine creek.

SHOSHONE COUNTY

The Reindeer M. Co. is planning to erect a mill, to be in operation next fall, on its property in the Wallace district of the Coeur d'Alene. The work in hand consists of driving and cross-cutting on the vein from the shaft level. Two large bodies of good milling ore have been developed. The first shoot was 75 ft. long and 15 ft. wide, and the second shoot has been driven on for 125 ft. The cross-cut has shown this to be 22 ft. wide.

It is reported that the 150-ton concentrator at the Alice mine will be put in operation in the near future. Development is to be resumed at the Ray Jefferson property in the Sunset district.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—Of the independent producing companies in this district, none is making a better showing than the East Butte, and in the course of a few months the company will be earning a good profit on its operations. For several months improvements looking to the reduction of costs have been in progress, and it is now claimed that the company is in a position to put copper on the New York market in competition with the leading producers of the country. This condition of affairs has been largely brought about by Oscar Rohn, manager for the company. In the next few months the smelter will be in a position to turn out 1,500,000 lb. of copper

per month at a cost of about 9c. per pound. The sintering plant recently finished is one of the most important improvements made in the past few months. With it the flue-dust is carried back to the blast-furnaces for re-treatment, bringing about a saving of at least 5% of what was formerly a complete loss of about 8% of the mineral content of all ores treated. As the process is largely automatic, the cost of operation is comparatively light. This will add considerably to the earning power of the company. The plant has a capacity of treating 100 tons of flue-dust every 24 hours. It is adjoining the smelter and close to the adits beneath the new dust-chamber which was completed a few weeks ago.

An effort is to be made by W. A. Clark to operate the Moulton mine, this time as a silver property. A year ago the shaft was repaired and some work done, but a shipment of ore sent to Salt Lake did not turn out well, as the process under which the ore was treated did not separate the zinc, iron, and silver satisfactorily. It is now claimed that a process has been perfected which will treat the Moulton ore at a profit and that on the strength of this the mine is to be reopened and shipments of ore made to Salt Lake City. It is more than twelve years since the Moulton mine has been a producer. Previous to the silver panic it was a profitable property.

Butte, March 4.

NEVADA

ESMERALDA COUNTY

(Special Correspondence.)—The estimated February production of the Goldfield Con. Mines Co. was 27,641 tons of ore, with a gross value of about \$685,000. Operating expenses amounted to \$210,000, leaving a net profit for the month of \$475,000.

Goldfield, March 4.

The report of the Florence Goldfield M. Co. for the year ended December 31 shows that the company operated for that period with a deficit of \$42,008. The year closed with the company having \$44,098 on hand. During the year the management did 11,699 ft. of development work. The production for the year was 48,874 tons of ore, which yielded about \$252,821. The loss caused by the burning of the mill last December is estimated at \$212,481, after proper deductions were made for depreciation and insurance.

HUMBOLDT COUNTY

The shaft now being sunk on the north end of Winnemucca mountain by Bert Shively and associates has intersected a vein of rich ore, according to recent advices. The shaft is down 30 feet.

LYON COUNTY

(Special Correspondence.)—The Mason Valley smelter at Thompson has one blast-furnace in operation and has smelted as high as 560 tons of charge per day. The matte is being shipped to the Garfield smelter. Within the next two months the second furnace will be blown in, as the Nevada-Douglas and Mason Valley mines are expected to be shipping the necessary quantity of ore by that time. These two mines are now shipping 200 to 250 tons per day each, and will gradually work up to a 500-ton per day output. A considerable quantity of custom ore is being bought by the smelter. The Nevada-Douglas is also shipping about 150 tons per day of gypsum from its extensive deposit of that mineral, to the Western Gypsum Co. at Reno. This is 400 ft. thick, of unknown extent, and has the highest quality of any gypsum deposit in the Rocky Mountain region. Quarrying machinery is being erected to aid in its extraction.

Yerington, March 4.

NYE COUNTY

The Tonopah Belmont Development Co. has declared a dividend of 25c. per share. A similar dividend was paid January 1. The dividend, which will require \$375,000, will bring the company's total dividend disbursements up to \$2,843,000.

Press rumors are to the effect that the Rogers-Norton company, of New York, represented at Manhattan by F.

H. Mitchell, soon will commence development of the Toro Blanco group, recently purchased.

The Tonopah Mining company last week produced 3500 tons of ore. The production of other properties in the district for the week were the Belmont company, 2200 tons; Montana Tonopah, 1041 tons; Tonopah Extension, 990 tons; West End, 800 tons shipped and 44 tons to the smelter; the MacNamara, 400 tons; making a total of 8975 tons of ore from the district during the week. The gross value of the ore is estimated at \$224,375.

STOREY COUNTY

The Ophir company last week produced 298 tons of ore, estimated, of a gross assay value of about \$10,160. The shipments for the week included 356 tons of ore for the Kinkead mill. The Crown Point hoisted 773 cars of ore, and shipped 657 tons to the Yellow Jacket mill. The ore hoisted was valued at about \$5800. The Mexican mill, running 72% of the time, crushed 421 tons of ore with a gross assay value of \$9388. The Con. Virginia has changed the numbers of its levels to conform with the system used in other north end mines, and each level now has the same number in all of the mines. In addition to other work in the Con. Virginia, 29 cars of ore assaying \$23.12 per ton was mined. The preparation for the joint Best & Beleher and Gould & Curry winze has been completed. The United Comstock Pumping Association reported for the week the water-level as being 297 ft. below the 2200-ft. level station measuring point.

Bullion valued at about \$6000 was shipped March 2 from the South Brunswick lode by M. C. Murtagh. The bullion, which was the first shipment from the South Brunswick lode, was from ore from the Home claim, the ore having an average assay value of \$86 gold and \$2 silver. The Home is one of six claims in the Silver Star district owned by Mr. Murtagh. On March 3 the Mexican mill shipped five bars of bullion, valued at over \$10,000, to the smelter.

WHITE PINE COUNTY

(Special Correspondence.)—The Nevada Con. Copper Co. has five steam-shovels in action at Copper Flat, four on overburden, one on ore. Two are in action at the Liberty pit, one handling overburden, and the second mining ore. Churn-drills and steam-shovels are active on the hill situated between the Copper Flat and Liberty pits. A new 95-ton Bucyrus shovel is being tested and will probably go into commission soon. The company is reported to have recently extracted some high-grade ore from the Liberty workings. From the Veteran mine about 1100 tons of ore per day is being sent to the Steptoe smelter at McGill; 300 men are working at this mine. The Boston-Ely company has suspended operations. It is officially stated the company is planning to conduct prospecting with diamond-drills, this work to be done under contract. If results prove satisfactory, pumps will be erected, lower levels drained, and the Emma shaft sunk deeper. The Ely Con. company is arranging for the sinking of the Zack shaft from the 600 to the 800-ft. level. It is hoped to commence this work within a short time. On the 400, 500, and 600-ft. levels good quantities of ore have been opened. S. M. Levy, president of the company, recently inspected the holdings. The prospecting and development of lead-ore deposits in the Ely district is attracting much attention. The Lead King company reports the uncovering of a vein of steel galena ore averaging three to five feet wide. The ore is said to run about 70% lead, with some silver. Salt Lake people control the property, situated near McGill. The Ely Gibraltar is prospecting for lead on its holdings, several miles north of the Steptoe smelter. An adit has been driven 800 ft. and is being continued. Surface indications are considered to favor success. Other companies are active, and considerable ground is undergoing exploration.

Ely, March 1.

One of the eight units of the McGill concentrator is constantly operating on ore from the Veteran mine. For treating the Veteran ore, which is mined by the caving system, the jigs at the mill are being overhauled. Copper

Flat ores are treated without jigging. The McGill plant in Jannary produced 6,309,228 lb. of copper, the heaviest month since the record established in July 1910 of 6,896,429 pounds.

Advices from Ely state that A. D. Meyers has completed the purchase of the Panamint mine, on the west slope of Panamint range, near Telephone peak. Operation will be resumed under the direction of J. K. Turner.

UTAH

CARBON COUNTY

(Special Correspondence.)—W. G. Sharp, president of the U. S. S. R. & M. Co., representing interests connected with that company and with the Davis coal people in West Virginia, has purchased the Blackhawk Coal Co., having 1000 acres of coal land, and a controlling interest in the Castle Valley Coal Co., which owns 4400 acres, together with the Castle Valley Railroad Co., which runs from Mohrland to Price, on the main land of the Denver & Rio Grande railroad. He has also secured an option on the control of the Consolidated Fuel Co., which owns 3600 acres of land in the vicinity. If this option is exercised, which it is stated unquestionably will be done, these transactions in themselves mean the expenditure of \$2,740,000. The Utah Coal railroad, owned by the Sharp interests, will be built to connect these mines in Carbon and Emery counties with the San Pedro, Los Angeles & Salt Lake railroad. By the time the railroad is completed, it is stated that the mines mentioned will be brought up to a capacity of 6000 to 8000 tons per day. Options on additional coal land have been secured, in Huntington canyon and elsewhere, which will greatly increase the holdings of the company and make it a powerful rival of Gould's Utah Fuel Company.

Price, March 4.

WASHINGTON

FERRY COUNTY

O. B. Hollis, of Spokane, who has just completed an inspection of the Princess Republic property at Republic, reports the discovery of an excellent ore-shoot on the 600-ft. level, 400 ft. below the adit-level. Good shipping ore has been found on all levels. Plans have been completed for the resumption of work in the near future, and it is expected that the property will begin shipping this season. There is a wagon-road from the portal of the property to the Great Northern tracks.

SPOKANE COUNTY

William S. Thynng has been elected secretary of the Northwestern Bureau of Mines, which was organized in Spokane on February 28. William A. Nicholls is president, the secretary-treasurer being Ross Brattain. The Bureau has permanent quarters at 105 South Howard street.

STEVENS COUNTY

The American Tungsten Consolidated corporation, recently organized, has taken over the Germania mines and other important tungsten properties in the Cedar canyon district, and will work them as a group under one management. The Germania is equipped with modern machinery. The new owners will complete the mill, and plan the installation of an aerial tramway to convey ore to the mill. The corporation plans to open the three lower veins east of the Germania, where there has been little or no development at depth.

Conrad Woffle and W. G. Collins of Spokane have closed negotiations for a bond for \$50,000 extending over a period of two years on the Copper Queen group of seven claims lying just north of the United Copper Co.'s property. Four of the claims are patented. The property will be operated in connection with the United mine.

NICARAGUA

Pis Pis

It is reported from New York that the sale of the Bonanza mine has been effected in Paris. A dredging contract, in the vicinity of the Potosi mine, has been secured by Mr. Aramburu.

Among the Copper Mines

ISLE ROYALE in 1911 made a net profit of \$160,000, with a production of 7,500,000 lb. of copper at a cost of 10½¢. per pound.

THE MAYFLOWER M. Co., it is reported, has proved its vein for a length of 550 ft., the distance between No. 15 and 17 drill-holes, and for a width of 55 ft. The extreme depth was found to be 300 feet.

THE NAUMKEAG COPPER Co. will be organized, probably under the laws of Michigan, by the General Development Co., and will be capitalized at 200,000 shares of a par value of \$25. The property comprises 1260 acres on the south side of Portage lake, just west of Houghton, Michigan.

THE TUOLUMNE COMPANY will show a treasury surplus of about \$80,000 after having paid for all the improvements, including the new surface plant and the building of the railroad spur from the mine to the Butte, Anaconda & Pacific railroad connection. In another week the output will be increased to about 400 tons per day. In August next, unless something unusual occurs to retard the present showing, the dividends at the rate of 25¢. will be resumed. The showing on the 1800-ft. level has improved in the past week, and ore is being mined which runs as high as 12%. It is intended to ship a large amount of this ore in the next few weeks and keep the ore on the 1400 and 1600-ft. levels in reserve.

THE NORTH BUTTE COMPANY is not making any effort to develop the Edith May vein from the 2800-ft. level. Cross-cutting is going on in a northerly direction. From the 2800-ft. level the High Ore mine is to be entered, but it will be quite a long time yet before this is accomplished, as some 500 ft. is to be cut through. The purpose of this is to afford an exit from the property in case of necessity, and also for the purpose of affording the North Butte company a chance to take advantage of the High Ore system of drainage. On the various lower levels of the North Butte extensive development work is going on and some fine bodies of ore are being opened up, this being especially true of the Snowball vein on the 2200-ft. level, where the orebody is becoming larger and more valuable. A considerable quantity of the ore now going to the Washoe smelter is from this level, and some of it runs as high as 12% copper.

THE CHINO COPPER Co.'s first quarterly report for the period ended December 31, shows that the steam-shovels handled 1,938,000 cu. yd. of material, of which 377,000 tons went to the stock-pile. The average cost of the steam-shovels, stripping and mining, was a little over 31¢. per cubic yard. At present one shovel, working only part of the time, is supplying more ore than the mill can treat. Two units of the mill are in operation and the third will be put in commission in the near future. The two units under construction should be read in a few months, one in May, and the other on or about July 1. Drilling was discontinued at the close of September, and the last estimate of ore reserves, October 1, places the amount at 54,970,616 tons, averaging 2.24% copper, of which about 32,000,000 tons will be mined with steam-shovels. Although the ore has contained a large amount of carbonate, it has been of higher than average grade, and the recovery has been equivalent to high recovery from ore of ordinary grade. The cost of production in December was 8.3¢. per pound. The January cost was about 8½¢. per pound. Judging from the amount of ore treated at present, it is believed that the mill will be capable of handling a minimum of 5000 tons of ore per day. The report closes with the statement that with two units operating at full tonnage on the inferior quality of ore now being treated the cost of producing copper would not exceed 7¢. per pound. No difficulties have been experienced in the operation of the mill.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. H. MUNRO is in New York.

JAMES G. BERRYHILL was in town.

H. W. DUBOIS is in San Francisco.

E. C. DAMIN was in San Francisco.

F. L. LOWELL has returned from Idaho.

H. V. WINCHELL was in San Francisco recently.

PERRY SKILLMAN was in San Francisco recently.

J. WILLIAM SMITH was in San Francisco this week.

LIONEL LINDSAY has returned to San Francisco from London.

B. C. AUSTIN has been at Smartsville and Hammonton, California.

H. S. CHAPMAN has sailed for the Philippine Islands on mining business.

W. W. MEIN has gone to Arizona, and from there will go to Porcupine, Ontario.

JOHN W. GEIGER has returned to Salt Lake City from Humboldt county, Nevada.

A. E. DRUCKER was married to Miss MINNIE BARSTOW, at Seoul, Korea, February 14.

A. C. FRENCH is in charge of development at the Lost Josephine mine, near Provo, Utah.

S. S. ARENTZ, general superintendent for the Nevada Douglas Copper Co. is in San Francisco.

STEPHEN J. LETT is returning shortly from Sumatra, where he has been for the past three years.

CHARLES KIRCHHOFF was married to Miss ERWINA DIEPENBROCK on February 26, in New York City.

EDWARD M. RABE is at Magnolia, Boulder county, Colorado, conducting a series of mill and cyanide tests for the Cash mine.

THEODORE B. COMSTOCK has given up his work on the Board of Public Utilities and resumed general practice at Los Angeles.

M. A. NEWMAN has resigned as manager for the Cia. Minera Jesus Maria y Anexas, at San Jose de Gracia, Sinaloa, Mexico.

F. LYNWOOD GARRISON has been examining a mine in the South, but was at Toronto this week attending the meeting of the Canadian Mining Institute.

THOMAS N. MILLER has sold his engineering office at Nevada City, California, to C. W. WHITWELL, and will sail for Korea from San Francisco on March 12.

PAUL DE MONTCALM is a member of Ben S. Revett's party, which is prospecting in the Choco district, Colombia, for the Consolidated Gold Fields of South Africa.

A. H. PURDUE has been elected State Geologist of Tennessee to succeed George H. ASHLEY, resigned. Mr. Purdue's address is State Geological Survey, Nashville, Tennessee.

A. J. HOSKIN is now Western editor of *Mines and Minerals*, succeeding GEORGE F. DUCK, who is now principal of the School of Coal Mining of the International Correspondence Schools.

JOHN CARSON, the president, and SAMUEL W. COHEN, the general manager for the Crown Reserve Mining Co., Ltd, have gone to Europe for two months on business for the company.

S. W. YOUNG, of Stanford University, will give a talk before the Mining Association of the University of California on the 'Thiogen Process,' Wednesday, March 13, at 8 p.m., in room 200 Mining building. Mr. Young has made some very successful trial runs at Campo Seco with his process, and will have several lantern slides to illustrate his talk. The public is invited.

Monthly Copper Report

By JAMES LEWIS & SON

Under the influence of a fall in the price of securities on the New York Stock Exchange standard copper declined from £61 17s. 6d. for cash on February 1, to £61 on February 6. The very favorable American statistics showing a reduction of 10,346 tons in the stocks at the end of January and an increase of 9047 tons in the home consumption as compared with the same month last year, induced active buying of profits and standard advanced on February 9 to £63 cash and £63 15s. three months. This was followed by a fall to £62 7s. 6d. February 14; but the very material reduction in European stocks and in visible supply announced February 15 caused a sharp reaction to £62 17s. 6d. cash and £63 11s. 3d. three months.

Refined copper has sold only to a moderate extent, manufacturers showing little desire to replenish their stocks, which must now be considerably depleted. American electrolytic was offered at £65 per ton e.i.f. for March and £65 5s. for April delivery, but the quotation has since been raised 25s. per ton. In sulphate of copper more business has been transacted, and with the sale of the second-hand parcels pressed on the market, down to £21 15s. per ton for February delivery was accepted. There has since been a recovery, closing value February 15 being £22 15s. with buyers eager to acquire sulphate for delivery during February, as should a strike of the coal miners take place on March 1, its manufacture will be considerably diminished, if not altogether stopped.

Stocks in England and France have decreased 982 tons and in Germany and Holland 400 tons during the fortnight. American refiners' returns for the month of January show a reduction of 10,346 tons in the stocks, the production being 1590 tons less than for the previous month, and exports 414 tons more. The consumption was 1627 tons less than during December, but 9047 tons more than for January last year. The total reduction in American and European stocks is therefore 12,334 tons, or 65,598 tons less than on February 1, 1911, being 88,359 tons, against 153,957 tons twelve months ago. English and French consumption has increased 76 tons, and the exports of sulphate of copper are 31% larger than the large exports of January 1911.

	1911.	1912.
Imports from United States:	Tons.	Tons.

Consumption of England.....	10,363	10,693

Company Reports

TENNESSEE COPPER CO.

This company was organized in 1899 with a capitalization of \$5,000,000 in shares of \$25. It has outstanding \$1,500,000 in first mortgage 6% bonds, issued December 1, 1910, and to be completely retired by December 1, 1917. The mines are at Copperhill, Polk county, Tennessee. The financial report for the year ended December 31, 1911, is as follows:

	1911.	1910.
Total receipts	*\$577,926	\$547,158
Bond interest and discount.....	110,877	61,770
Depreciation account	60,000	40,000
Total	\$170,877	\$101,770
Net	407,049	445,387
Dividend		300,000
Depreciation of special reserve..	40,000
Surplus	\$367,049	\$145,387

*Including \$27,200 insurance received.

In his presidential report for the year, F. Lewisohn says: "At the end of 1910 the construction of the acid plant had been practically completed, with the exception of two Gay-Lussac towers, which it was found advisable to build in order to attain the minimum cost of producing acid. Owing to unfavorable weather conditions they were not completed until June. The entire plant was working harmoniously during the first few days, when a serious fire necessitated a complete cessation of operations for over a month, and a serious impairment of efficiency for over two months."

MUREX MAGNETIC COMPANY, LIMITED

This company was organized in London, April 15, 1909, to acquire from the Murex Syndicate, Ltd., its patent rights to a process for the wet concentration of ores by the magnetic method. The consideration was £89,993, payable in 59,993 fully-paid shares, and 60,000 shares credited with 10s. paid. The authorized capital is £120,000 in 120,000 shares of £1 each; all the shares are issued and fully paid; the final call of 2s. 6d. on 60,000 shares was payable October 20, 1909. The accounts to June 30, 1911, submitted December 21, 1911, show general expenditure, £24,244; cash, £163; Broken Hill South Extended debentures, £10,000; debtors, £517; creditors, £1454; loan and interest, £26,366. The price of shares February 15, 1912, was 1/2 to 3/4.

This company controls the A. A. Lockwood process of adding to ore magnetite or other magnetic substance together with some liquid to make the particles agglomerate with the sulphide or other valuable mineral to form granules susceptible to magnetic influence. Lionel Holland, chairman of the annual meeting held in December in London, reported that the test plant formerly at Broken Hill Block 14 mine has been removed, owing to lack of proper facilities for demonstration, to the Amalgamated Zinc (De Bavay's), where it will be observed by certain persons, who, if the process is a success, will acquire the Australian patent rights. To facilitate a thorough test in the district, the South Extended mine has been financed, this step being necessary as the directors of other properties consider the metallurgical problem satisfactorily solved. The company, assisted by friends, is to subscribe for a maximum of £55,000 debentures, to be paid in installments according to the success in development. For this, £30,000 will be spent, and later £25,000 will be provided for the plant. So far the development of the mine has been satisfactory, having proved the existence of large orebodies assaying about 24 1/2% zinc, 11 1/2% lead, and 2.8 oz. silver per ton. The process has given good results at the Cordoba mine in Spain, and the plant at Malines, France, where zinc-lead sulphide in a barite gangue is concentrated, is running continuously. As the ore had too little zinc to be profitable, the plant at St. Christoph, in south Germany, was closed.

Decisions Relating to Mining

Specially reported for the MINING AND SCIENTIFIC PRESS.

CONVEYANCE OF MINERALS—CONSTRUCTION OF DEED

A deed conveyed to the grantee all the metallic ore and mineral interest of every description, and all ore and mineral of every kind and quality, in or upon a certain described land, "with the exclusive right and privilege of entering upon said premises at any time hereafter to dig and mine for ore and mineral of every description, including stone, wheresoever the same may be found or wheresoever the said grantee may deem proper to excavate for the same, and to take out and remove, ship, sell, have, and dispose of all the mineral and metallic ore of every description found in or upon the aforesaid premises, with the right of ingress and egress to and from the mine in every direction, the water privilege for washing ore and the right for erecting small houses for the accommodation of the hands employed in working the mine and also the right of removing the said buildings or houses and to have the right and privilege of purchasing the said premises at any time within 25 years from the date thereof for the sum of \$600, payable in cash on delivery of deed to same." The habendum clause provides that the grantee was to have and hold such metallic ore and mineral interest, with all the rights and privileges granted, to his heirs and assigns for their use, benefit, and behoof forever in fee simple. On the construction by the court it was held that the instrument was not a lease of the mineral interests in the land for the period of 25 years, nor a mere option or right to purchase such within that period for the sum of \$600, payable in cash; but it conveyed to the grantee all the minerals described in the land, together with the right of purchasing all the remaining interest at any time within 25 years from the date of the instrument for such cash consideration.

Lanham v. Henry, (Georgia) 69 Southeastern, 552. November 1910.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

PROFITS AND WAGES IN THE BRITISH COAL TRADE. By Thomas Richardson and John A. Walbank. Pp. 96. The N. A. C. C., Newcastle, 1911. For sale by the *Mining and Scientific Press*. Price 35c.

This little pamphlet is a discussion of wages and profit in the Durham coalfield, by a member of Parliament and a chartered accountant. It is divided into three parts; the financial position, the economic aspect of the minimum wage, and the consumer. American students of economic and social problems will find much of interest in this detailed study of conditions under a more highly developed social organization than our own.

HAZELL'S ANNUAL FOR 1912. By Hammond Hall. Pp. 592. Hazell, Watson & Viney, Ltd., London, 1912. For sale by the *Mining and Scientific Press*. Price \$1.50.

This well known British Annual, now in its twenty-seventh year of issue, though primarily intended for the subjects of Great Britain, will also be useful and helpful to Americans. The 'almanacs' published in America cover only in part the field of this volume, which gives much fuller details on economic and political questions of the world at large, as well as furnishing a complete dictionary of reference on British affairs. As examples of its up-to-dateness may be mentioned the abstract of the provisions of the Anglo-Russian convention regarding Persia, a summary of Sir Edward Grey's speech on the Morocco question, and the amendments to the insurance bill.

CENTRAL BANK OF THE UNITED STATES. By E. Clyde Robbins. Pp. 182. The H. W. Wilson Co., Minneapolis, 1910. For sale by the *Mining and Scientific Press*. Price \$1.

Two characteristic features of modern life are that the average man needs a wide fund of information on indus-

trial, economic, and political questions of the day, and that the amount of literature dealing with these topics is so great that even a specialist can scarcely keep up with it. Daily journals are of little use, for they are notoriously inaccurate and are usually partisan, while discussions in serious magazines spread over such long periods that the interest is lost. To all such this small and inexpensive volume will be of great service. It has been prepared primarily as a syllabus and digest for debating societies, and therefore endeavors to give all shades of opinion. The independent thinker will welcome this, but those who prefer predigested opinions will perhaps end its perusal with a feeling of uncertainty.

MINING MANUAL FOR 1912. By Walter R. Skinner. Pp. 1500. Walter R. Skinner, London, 1912. For sale by the *Mining and Scientific Press*. Price \$5.25.

Skinner's 'Manual' is almost as indispensable as a dictionary, in many ways, and it is only to be regretted that it deals only with British companies, or companies having British affiliations. Several feeble imitations of it exist, dealing with American companies, but none are worthy of comparison. Apparently the American volumes are poor because but few are purchased, while but few are purchased because they are so poor. Skinner's 'Manual' finds a most practical and pleasing testimony to its quality in its general use. The form of the volume under review is unchanged from last year, and it differs from its predecessor chiefly in containing the latest incorporations and latest prices, to January 15, 1912. English deliberation and American speed are stock phrases, and it is interesting in this connection to note that the British annuals appear months ahead of their American prototypes.

Commercial Paragraphs

THE AMERICAN AGENCIES, LTD., 608 South Olive street, Los Angeles, California, acting as Pacific Coast Agents for Eastern manufacturers, are making arrangements to open additional offices in San Francisco, Portland, and Seattle. The company is now in a position to take Eastern lines and place them effectively in the hands of both jobbers and retailers on the Pacific Coast, to see that the most effective outlet is found and that sufficient credit is behind houses dealt with.

SMITH, EMERY & Co., assayers and metallurgists, Los Angeles and San Francisco, announce as shortly ready for custom work, one of the best equipped ore testing plants in the country. The heavy machinery is being installed in separate buildings in the rear of the main building on their property in Los Angeles. The machinery now being set up consists of a full-sized stamp-mill, elevators, amalgamation plates, concentrating table, classifiers, pumps, cyanide leaching and agitating plants, filter, tube-mill, large and small crushers and grinders, furnaces, etc. A full equipment of preliminary apparatus has been installed, and other machinery will be added as rapidly as there is a demand and it can be taken care of.

The INGERSOLL-RAND Co., of 11 Broadway, New York, has issued a bulletin, No. 4111, descriptive of its type BC butterfly hammer drills. These drills are equipped with telescope feed and can also be furnished with dust allayers, which are strongly advocated as a safeguard to the health of the miners. Water can be sucked up 6 or 8 ft. from a pail or bucket, no tank or pressure line being necessary. This makes the use of the water spray possible under all conditions, no matter how small the working or how far away from the source of water supply. The butterfly valve consists of two wings and a central stem on which it oscillates. One wing controls the supply to each end of the cylinder, the other wing controlling the exhaust. As the two wings are of the same area, the pressure holding the supply wing on its seat is equalled by the pressure tending to force the exhaust wing off its seat, thus making a balanced valve which requires very little pressure to shift it. The valve closes the ports by advancing to the seat, not by sliding on the seat, thus making a better fit the longer it runs.

EDITORIAL

NOW that a Norwegian explorer has reached the south pole, lovers of adventure will sigh for more difficulties to conquer.

ARBITRATION treaties with Great Britain and France have been adopted by the Senate, after subjecting them to emasculation. General arbitration seems to have fared but little better than reciprocity.

POCKETS of high-grade gold ore are not infrequently found in the veins of Nevada county, California. Recently Mr. Murray I. Scott made such a discovery on the Eureka ground near Grass Valley, and now it is announced that the lease that he supposed he held was granted by an unauthorized person; all of which contains interesting suggestions as to titles in the California goldfields.

SPOKANE has won in the contest for the privilege of entertaining the American Mining Congress next November. The last meeting having been held in Chicago, it is appropriate that the next should be in the West. Philadelphia would undoubtedly have proved a generous and attractive host, but as a newcomer among the cities interested in the Congress, may appropriately be asked to wait until another year.

DEMOCRACY is not confined to republics. On Sunday last Mr. George W. Goethals, chief engineer of the Panama canal, lunched with William III, Emperor of Germany, at the palace in Berlin, and two forceful and capable men discussed canals and their construction. The invitation was a pleasing tribute to the notable contribution which the engineer has to make in the control of the forces of national and international life.

PORCUPINE is to celebrate with a banquet the opening of the mill at the Dome Mines. We trust there may be many happy anniversaries of the day. The Dome is a property of demonstrated value and large additional prospects. In planning the underground workings and the mill the owners have profited by the best technical advice, and a long and profitable period of production is safely anticipated. We expect shortly to publish an account of this and other properties at Porenpine, written by Mr. T. A. Rickard, who is now visiting the district.

PRELIMINARY sorting may make the difference between success and failure at a mine, and we are therefore glad to print a description of the plan adopted at El Tigre, written by Mr. J. W. Malcolmson, consulting engineer, and L. R. Budrow, manager, for the company owning that famous and rich mine. The peculiar feature of the plant is the superimposed belts. Coarse rock passing over the grizzly is delivered to the upper short belt and passes before the pickers. They sort out high-grade ore. The rejected material passes on and joins the fine material that has gone through the grizzly and constitutes the mill-feed. Such an arrangement is simple and compact, and clearly

could be used with equal facility in a place where it was desirable to increase the value of the feed by picking out coarse rock. This is a situation that often confronts the manager.

DIVIDENDS for the second half of the year, it is announced, will be passed by the Central Mining & Finance Corporation, the concern that increased its capital stock £1,500,000 last year in order to absorb the properties of H. Eckstein & Company, and Wernher, Beit & Company, on the Rand. Depreciation of investments is given as the cause.

ALASKA and its needs are thoughtfully reviewed in the recently distributed annual report of the Governor, Mr. Walter E. Clark. Unfortunately, the exigencies of politics render it unlikely that any considerable remedial legislation will be exacted at Washington this winter. It is to be hoped that some at least of the excellent suggestions made by the Governor may be adopted. Because there are differences of opinion regarding the leasing of coal lands is no reason why land surveys should be slighted or steamers should be sunk for want of adequate charts and lights.

PETROLEUM prices in the West Side fields of Kern county, California, have advanced five cents per barrel. This is a change in the right direction, since under ruling quotations the producers have not been able to make a fair profit. The new prices range from 35 to 60 cents per barrel, depending on the specific gravity of the oil. It is roughly estimated that in territory where the sands are not more than 3000 feet deep and wells are of the average productivity, operators should make 15 per cent on their investment with oil at 50 cents per barrel. In view of the large number of inevitable failures and the always present risk, this is not an unreasonable return. It should be remembered that if waste in production is to be decreased the actual operators must be allowed a reasonable profit on the business. Invasion of the wells at Bakersfield by water is becoming a serious problem. The operators are in consultation now with Mr. W. H. Storms, State Mineralogist, and some means of protecting the producing wells must be found. Any remedy adopted will involve spending money and must add to the cost of production, however great may be the final economy. Cheap fuel is a great boon to any community, but cheapness may cost too much in waste. As Mr. G. W. Traer has recently shown in regard to coal mining in the Middle West, and Mr. M. L. Requa has argued in the case of California, unregulated competition, while lowering prices, may bring in its train results more serious to the community than the slightly higher price that might be expected to follow a combination exercising a reasonable control over production.

MODIFICATION in the wording of the Foster bill for reorganization of the United States Bureau of Mines, now before the House, and recently also introduced in the Senate by Mr. Miles Poindexter, has removed all valid objection to it from those who feared an incursion by the Bureau of Mines into the field of private testing. Under the terms of the revised bill, neither the Bureau nor any employee will be authorized "to undertake any investigation or operation in behalf of any private party, except for the health and safety of persons employed in the mining, quarrying, metallurgical, or other mineral industries, and with the approval of the Secretary of the Interior." This exception is necessary, as we have already shown, in order to allow testing of powders to determine which it shall be permissible to use in coal mines. When the work is done without any charge there is a tendency on the part

of some manufacturers to abuse the privilege of having such tests made. On the other hand, official tests are necessary if the real purpose of the work is to be served. It is further provided that employees of the Bureau shall have no personal or private interest in any mine or the products of any mine under investigation, though outside experts, not subject to this restriction, may be employed temporarily in a consulting capacity. The spirit of economy so prominent in the present Congress, which has been debating whether to add \$25,000,000 or \$70,000,000 per year to the pension charge, is shown in the provision that no such expert shall receive "to exceed ten dollars per day." This is a brilliant example of economy as understood by Congress and a slap at mining and metallurgical engineers. However, any expert who may serve the Bureau is apt to do so from interest in the work rather than from the hope of monetary reward, and if fair salaries be paid to the men permanently employed, the outsiders will not quarrel over money matters. It is fundamentally absurd to hamper the Director of any technical bureau with such a petty restriction and lends point to the widely current suggestion that what Congress does not want is expert advice, either upon the tariff or any other subject.

Alaska Copper Mines

Payment of \$1,000,000, the initial dividend of the Kennicott Mines Company, which owns the Bonanza copper mine in Alaska, has attracted much attention. It is less than a year since shipments from this property began, and in tonnage the output has so far been small. The ore is, however, unusually rich. Cargo shipments have assayed 71 per cent in copper, and there is a content of 8 to 20 ounces of silver as well. This is more like matte than ordinary copper ore, and quick and large returns are to be expected. How many such dividends can be paid is less certain. The Kennicott Mines Company is controlled by the Alaska Syndicate, and we believe no official estimates of the ore reserve have been published. Mr. L. W. Storm is quoted in 'The Copper Handbook' as estimating 80,000 tons of ore containing 50 per cent of copper in the main orebody, and 50,000 tons of 12 per cent ore in the large talus spread on the face of the mountain below the outcrop. In addition, there is an unestimated amount of ore containing 3 to 20 per cent copper and lying in and around the high-grade ore. Another estimate lumps the whole mass at equal to 100,000 tons containing 65 per cent copper. Our own visit to the property was entirely too brief to permit of making even an approximate estimate. The total amount of copper present is evidently large, though not unlimited. When the concentrating plant now being built is completed, much of the low-grade ore can be treated at a profit, and as the orebody is essentially a replacement of the Chitstone limestone by chalcocite, it may be expected to prove extremely irregular. Contrary to the opinion held by many geologists, we believe the Bonanza orebody to be the result of the ordinary processes of secondary enrichment, and find explanation of its preservation in the fact that it occurs in a high ridge which rises above the upper limit of glaciation. Other veins in the same region do not show the same secondary chalcocite because the glaciers have cut deep into the orebody and eroded the secondarily enriched cap. Under this hypothesis the primary orebodies are not likely to be of value comparable to that of the orebody now worked in the Bonanza mine.

The Kennicott Mines Company is capitalized at \$3,000,000, and it is said that the final profit on the Bonanza mine was considered likely to be about double the capitalization. To get at the real profit on the transaction, in-

interest and deferred charges would need to be taken into account. The mine has been excellently handled, and every effort has been made to assure a quick return on the investment: the soundest of policies where a rich ore is available. As a mining venture the Bonanza mine shows every promise of brilliant success.

To render available the copper in the Bonanza orebody, it was necessary to build the Copper River & Northwestern railroad, and this was accordingly done, the line being opened for traffic last spring. This road is 195 miles long and cost, according to figures from the engineers' books, \$16,500,000 in round numbers, including equipment. The Copper River & Northwestern railway is capitalized at \$5,000,000 and has a bonded debt of \$50,000,000, secured by a first mortgage on the property and calling for 5 per cent interest. The bonds are dated February 1, 1909, and run till 1959. This capitalization of \$55,000,000, it will be remembered, has nothing to do with the mine and is based on a road costing less than one-third of that amount. In addition, the Alaska Syndicate owns the Alaska Steamship Company and has expended money liberally in other directions. Current popular estimates credit the Syndicate with investments totaling \$25,000,000, which probably is conservative. The total capitalization would run much beyond this figure. Beatson's Bonanza, an excellent property, is owned by the same people, though whether it is a part of the holdings of the Alaska Syndicate, is not certain. In any event, shipments from it do not enter into the problem of supporting the Copper River & Northwestern road. For that, as yet, ore from the Bonanza mine must be the main source of traffic. It was stated recently that the railroad was now earning its operating expenses. It is difficult to see how much more than that can be expected until more mines are developed, and, while prospecting is active at a number of properties, it is but fair to say that the result is still far from certain. The initial dividend of the Kennicott Mines Company is gratifying, but Alaska still is far from flooding the copper market.

The 'Blue Sky' Law

It is one of the hopeful signs of the times that serious and successful efforts are being made to enact legislation that will minimize, if not entirely prevent, the promotion of 'wild-cat' mining companies such as have brought marked disrepute upon mining in the United States. Both the American Mining Congress and the Mining and Metallurgical Society have done good work in agitation for such a reform. One of the most successful measures yet enacted is the so-called 'Blue Sky' law of Kansas.

The Kansas measure is entitled: 'An Act to Provide for the Regulation and Supervision of Investment Companies.' It requires every corporation or association, foreign or domestic, which proposes to sell stock in Kansas, to file with the bank commissioner a clear and complete statement of the company's affairs, down to the minutest details; to file a written and irrevocable consent to accept service through the Secretary of State; and to pay the expenses of a thorough investigation by the bank commissioner's office. Books must be kept according to the regulations set forth in the act, and the books must be open at all times to any shareholder. The sale of any stock in the state of Kansas without compliance with these regulations subjects the agent to a maximum penalty of \$5000 fine, or 90 days in jail, or both. False statements made on applications for a certificate subject the applicants to a fine of from \$200 to \$10,000, coupled with a jail penalty of from 1 to 10 years. Any company which attempts to conduct its affairs in violation of these regulations is subject to be placed in the hands of a receiver, and its affairs wound up by the state

banking department. A similar bill is proposed in Illinois and has been endorsed by the bankers association of that state. Mr. B. F. Harris, the energetic president of that powerful organization, is leading in an active campaign for its enactment. A bill of the same import is now before the New Jersey legislature with excellent prospects for passage, and in other states the matter is being actively discussed. In California promotion of the Mascot Copper Company with inadequate publication of data regarding either the company or its mines, has called attention to the need of compelling complete statements to be made prior to attempts to sell stock to the public. Even in Wall Street the matter is attracting attention and the proposal finds many friends. There is no place where drastic regulations of this nature are so much needed as in that great market, where there have been so many instances of exploitation of the public through misrepresentation, ranging all the way from simple exaggeration to the most flagrant and fraudulent misstatements. The mining industry has suffered for many years from the obloquy placed upon it by the operations of the gentry who have dealt in alluring literature, but who have had little or nothing to do with actual mining operations. The most spectacular effort of the Government to put a stop to manipulation of this nature was the recent prosecution of Mr. George Graham Rice, whose trial was prolonged for a period of nearly six months, finally coming to a lame conclusion last week by the Government accepting pleas of guilty on the part of Mr. Rice and Mr. B. H. Sheftels, the former as the principal defendant receiving a jail sentence of one year, while in the case of the latter, sentence was suspended. The expense to which the Government was put in the matter is estimated at \$150,000 or more. The general comment is that the 'mountain labored and brought forth a mouse.'

In addition to the examples against which the Federal law department has exerted its efforts, there have been some final chapters written recently that could hardly have been written had the public had the protection of some such measures as the 'Blue Sky' law mentioned. Recently the Securities Corporation, a holding company that fathered a number of large operations in Guanajuato, Mexico, sold all of its assets in the form of shares in its subsidiary corporation, and proceeded to go out of business with practically a total loss to all its shareholders. The same procedure has just been completed by the Development Company of America, on account of which the trustees sold at auction last week large blocks of stock in its subsidiary corporations, liquidating all of the assets of the holding company. The Development Company of America was interested in a large operation at Tombstone, the Tombstone Consolidated Mines Company, promoted the Imperial Copper Company at Silver Bell, Arizona, and was interested in the London-Arizona Copper Company, the Saddle Mountain Mining Company, and the Look-Out Copper Company. In the case of each of these holding companies and their respective subsidiaries, the shares were sold to the best class of investors—country bankers, professional men, and newspaper men—all of whom are now bitter toward mining enterprises, and in that frame of mind which declares that 'no good can come out of Nazareth.' The aggregate sums invested in the various enterprises under discussion were large. Had they been placed legitimately along conservative lines in properties modestly capitalized, and bought at lowest prices for the stockholders, there would be a regiment of mining enthusiasts throughout the country, instead of a regiment of disgruntled losers unwilling to look at any kind of a mining venture, good, bad, or indifferent. No part of the community is so vitally interested in preventing the recurrence of such collapses as those who are in the mining industry.

Preliminary Handling of Ore at El Tigre

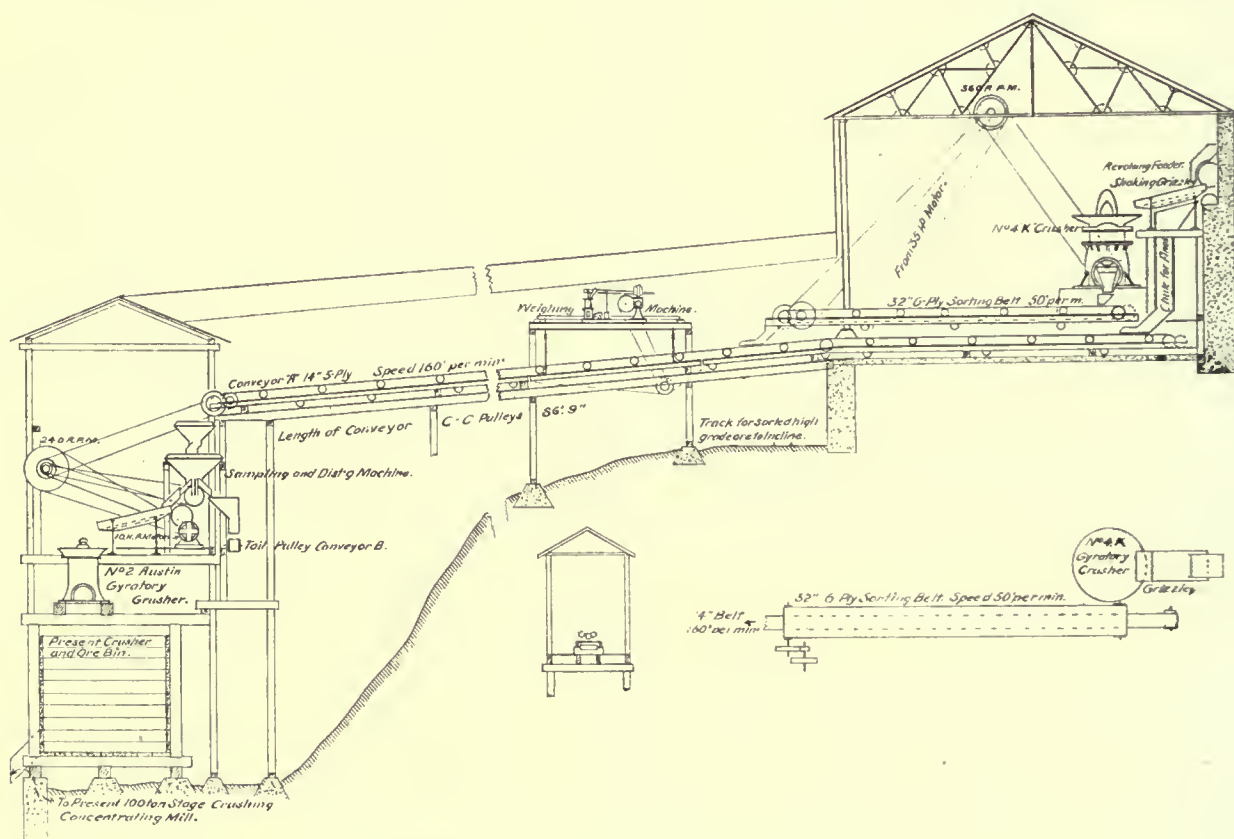

By J. W. MALCOLMSON and L. R. BUDROW

The El Tigre mill, belonging to the Lucky Tiger-Combination G. M. Co., is situated in Sonora, Mexico, 30 miles from any railroad. Power is supplied from Douglas, Arizona, over a line built during the revolutionary troubles of last year, and it is interesting to note that despite the fighting at Agua Prieta, through which the line passes, not a day was lost during the period of construction. The mill, of which a general view is shown opposite, and which was designed and built by D. L. H. Forbes, was put in operation July 1, 1911.

The sorting arrangement here described was designed for a capacity of 600 tons in 24 hr., but at present is used on the day shift only. All second-class or mill ore is trammed from chutes on the lowest adit-level over 3000 ft. to a circular steel bin, of 15-ft. diameter and 30-ft.

amount of ore fed at each forward movement of the drum and facilitates the passage of large pieces of ore.

From the drum, the ore falls upon a shaking grizzly, 6 ft. long by 4 ft. wide, with bars, 2 by $\frac{3}{4}$ in., spaced 2 in. apart. The grizzly is operated by a quick-return eccentric drive. The undersize from the screen falls into a short chute or funnel which delivers it upon a $\frac{1}{4}$ -in. conveyor-belt, traveling at a speed of 180 ft. per minute. The oversize falls into a Gates type K No. 4 gyratory crusher, which reduces the ore to a size that will pass a 2-in. ring. The crusher feeds on to a 32-in. picking-belt traveling 50 ft. per min. This travels continuously at 50 ft. per min., and 4 men are employed, 2 of them being ore-sorters, who stand on opposite sides of the belt and throw down and to one side. W. W. Mein has sug-

ARRANGEMENT OF CRUSHERS AND SORTING BELT.

height, and having 250 tons capacity. A track carried on trestles leaves the main line, passes over the top of the bin, and joins the main track beyond. The loaded cars run over the top of the bin and, without changing direction, are carried forward to the main track, returning on the main line along the hillside to the mine. All underground tramping from the chutes to the bin is done with mules, and the present output of 200 tons per day can easily be handled with three mules during the day's shift. The cost of tramping is 11c. per ton. By changing to electric haulage, the cost would be reduced to 4c. per ton.

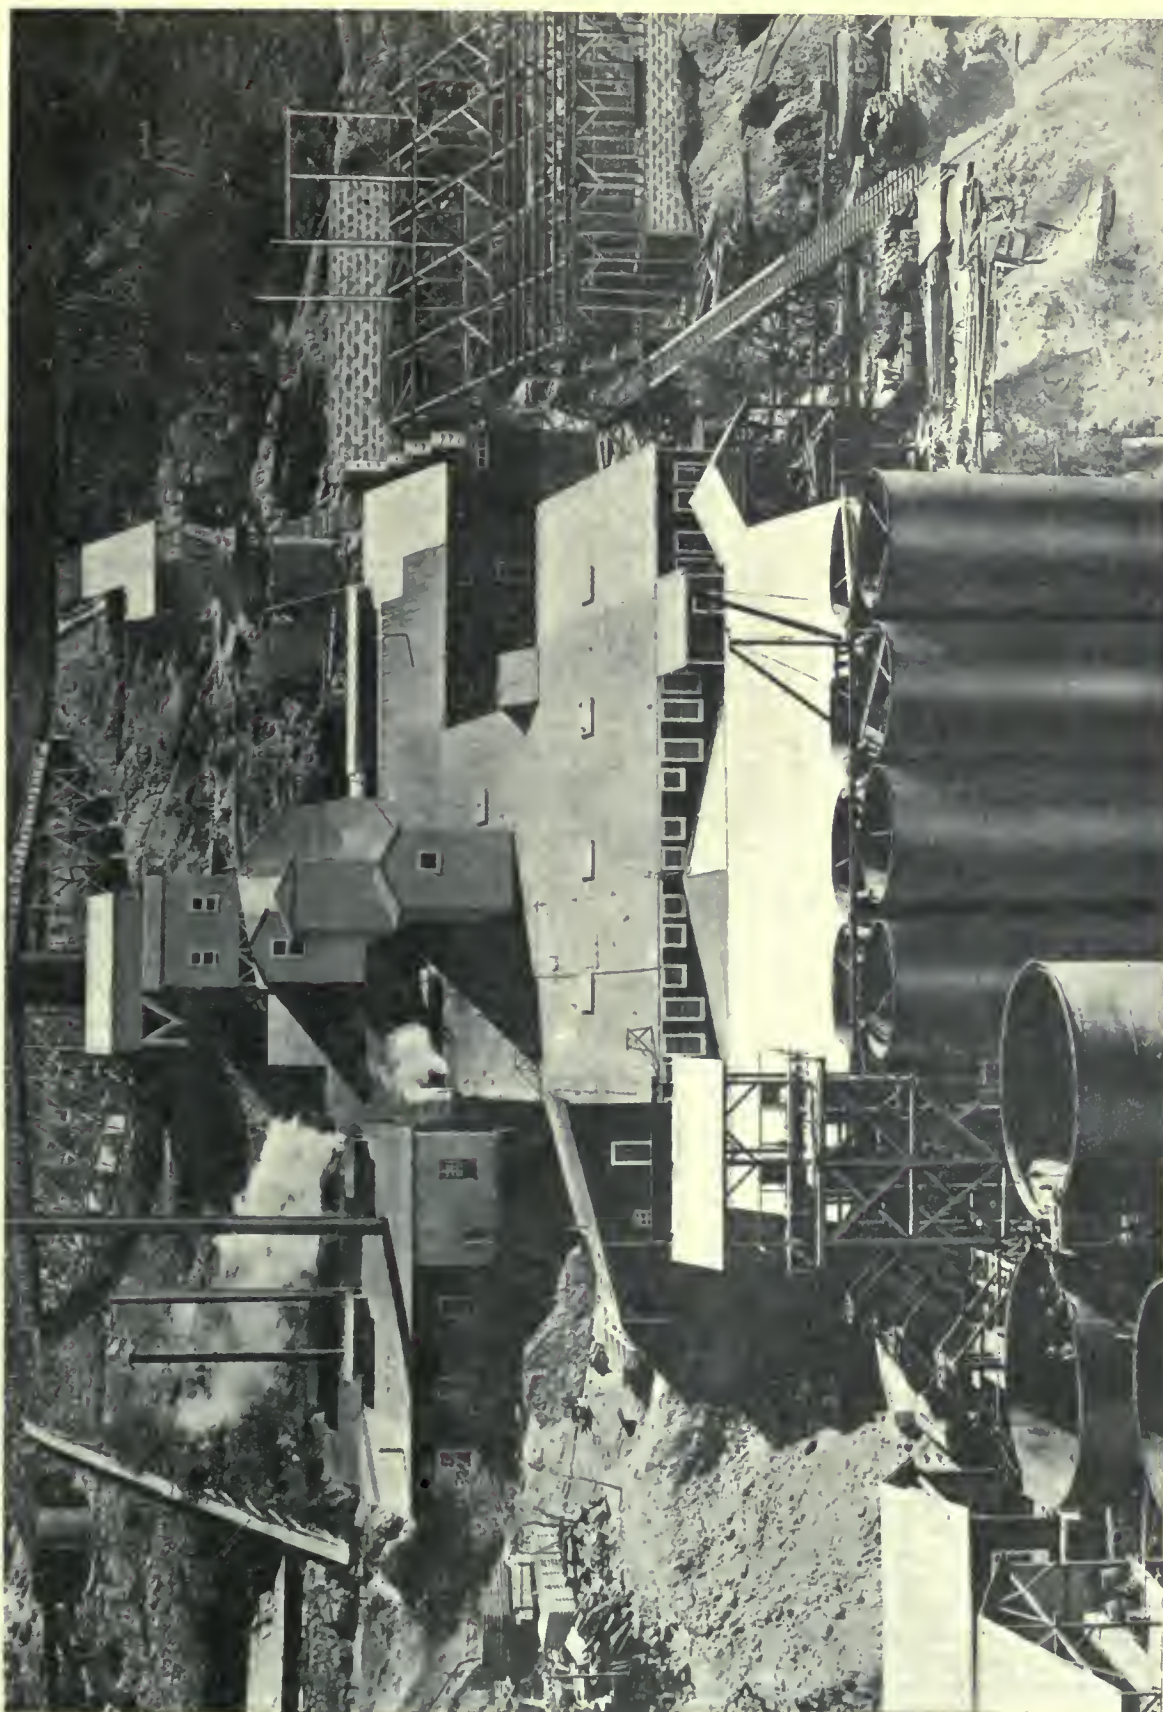

The circular steel ore-bin has a flat concrete bottom, 8 in. thick. The bin is made in 5 sections, the lower 2 being of $\frac{3}{8}$ -in. steel; the next 2 of $\frac{5}{16}$ -in. steel; and the upper section, $\frac{1}{4}$ -in. steel. The top and bottom are stiffened with rings of $1\frac{1}{2}$ -in. angle-iron. The ore is drawn from the bin by means of a revolving drum of 24-in. diameter and 27-in. width. The mechanism for turning the drum consists of an eccentric with a 1-in. throw operating a friction wheel of 12-in. diam., keyed to the drum shaft. A rack-and-pinion gate above the drum regulates the

gested as a preferable arrangement an intermittent movement of the belt in order that the sorters may work to better advantage. This is used in South Africa, the belt moving several feet, then stopping for a few seconds and starting again. Such an arrangement permits each ore-picker to handle the same area under equal conditions.

The high-grade ore sorted from the belt during December 1911 amounted to 6 $\frac{1}{2}$ tons, assay value \$310 per ton; the waste sorted out was 34 $\frac{1}{2}$ tons, assay value \$1.90 per ton. The ore milled, after deducting 125 tons of high-grade sorted while mining, and the sorted products mentioned, assayed \$20.25 per ton. The Gates crusher and picking-belt are housed in a steel-frame building. The arrangement is shown in the accompanying figure.

The ore from the picking-belt falls on the 14-in. conveyor-belt running underneath. It here joins the undersize from the grizzly and is weighed by a Blake-Dennison automatic weigher while in motion. This machine works admirably, recording the weight of the ore with an error of less than 1 per cent.

The ore from the 14-in. conveyor falls into a revolving cone distributor, which in turn discharges on a stationary

EL TIGRE MILL, SHOWING CYANIDE AND STAMP-MILL ADDITION.

cone divided into three segments. This arrangement divides the feed into three portions. One portion, representing 5%, goes to the sampling plant, and the remaining 95% falls into two compartments with an adjustable partition permitting the distribution of ore to the old stage-concentrator or to the new stamp-mill in the proportions desired.

The ore for the old concentrator falls on a second shaking grizzly with bars spaced $\frac{3}{4}$ in. apart. The undersize falls directly into the old 125-ton ore-bin, and the oversize runs through a No. 2 Austin gyratory crusher and is reduced to pass a $\frac{3}{4}$ -in. ring, falling into the 125-ton

bin. The other compartment of the stationary cone discharges on a 12-in. conveyor-belt traveling 200 ft. per min., and delivers the ore by means of a Robins automatic tripper into a 350-ton wooden ore-bin above the new 20-stamp mill.

The 5% sample falls into a 7 by 10 Blake crusher and is reduced to $\frac{1}{2}$ -in. size. The crusher discharges into a Snyder disc sampler, eliminating 95% of the sample; the remaining 5% is passed through a 2 by 6 Sturtevant roll jaw crusher and quartered down on a steel plate until the quantity is reduced to 50 lb., when it is sent to the assay office.

The total power consumed in this preliminary crushing, conveying, sorting, and sampling amounts to 14 hp. It requires 4 men to operate this portion of the mill. One is employed at the Austin crusher and sampling plant, and the remaining three on the picking-belt and at the Gates crusher. The total cost, including power, labor, and repairs, amounts to \$9.50 per day, or 55c. per ton of ore.

Gold and Silver Production of British Columbia, 1911

The preliminary estimate of the gold and silver production of British Columbia during 1911, by William Fleet Robertson, Provincial Mineralogist, shows a gold output of \$5,120,465, a decrease of \$952,915 compared with 1910, and a silver production of \$972,946, a decrease of \$272,070.

GOLD.—There appears to have been a decrease of about \$70,000 in the value of placer gold recovered in 1911, and of 42,000 oz. or about \$880,000 in lode gold, as compared with the production of 1910.

Placer Gold.—Practically all the placer gold comes from the Cariboo and Cassiar districts, only about one-thirtieth part of the total production coming from the remaining districts of the province. A rough apportionment of decrease places \$23,000 against Cariboo and \$47,000 against Cassiar. The larger portion of the decrease seems to have been in Atlin division of Cassiar district, about \$45,000; next to this is that of Cariboo division, of the district of the same name, about \$18,000; while the yield of Omineca, also in Cariboo district, is estimated at \$5000 less than in 1910. There is a possibility that Quesnel division of Cariboo did better than in 1910, but this cannot be determined until after the returns shall have been received from the larger operators in that division. The gravel-washing season was shorter than usual in both Cariboo and Cassiar, hence the smaller total recovery of gold. There is encouragement in the fact that in both districts provision has been and is being made for operating on a large scale in the future. Placer mining on a small scale is done in several parts of Fort Steele division of East Kootenay; in Nelson, Revelstoke, and Trout Lake divisions of West Kootenay; in Boundary, Similkameen, and Yale districts; and in Lillooet and Clinton, which last-mentioned divisions yield twice as much placer gold as any other of the smaller producing districts.

Lode Gold.—This preliminary estimate makes it appear that less lode gold was produced last year than in any other year since 1907. About one-half of the decrease resulted from suspension of production at two or three Boundary district mines, though this was in part compensated for by larger production by the British Columbia Copper Co. and Hedley Gold Mining Co. Again, there were several individual decreases in Nelson mining division, though in other instances the reverse was the case. Approximate figures of totals of lode gold from individual districts give an apportionment about as follows: Rossland, 117,000 oz.; Boundary, 51,000 oz.; Similkameen, 30,000 oz.; Nelson, 20,000 oz.; and Coast, 7000 oz. Of Rossland mines (which are in Trail Creek mining division), the Consolidated Mining & Smelting Co.'s Centre Star group produced nearly three-fourths of the total, while the mines of the Le Roi No. 2, Ltd., yielded the greater part of the remainder. Hereafter the production of the Le Roi (not of Le Roi No. 2) will probably be included in that of the Centre Star group, for the Consolidated company last summer added that mine to its other properties in Rossland camp. In the Boundary district the bulk of the gold was from mines of the British Columbia Copper Co. and the Granby company, while in Similkameen the Hedley Gold Mining Co. made a production estimated at the quantity above shown. In Nelson, the Queen, Granite-Poorman, Nugget, Arlington, Second Relief, and Yankee Girl mines together made up the output of lode gold from that division. On the Coast the Marble Bay mine was the chief producer and the mines

of the Portland Canal Mining Co. yielded the bulk of the remainder.

SILVER.—Of the estimated total production of 1,920,000 oz., Sloean mines contributed about 875,000 oz.; East Kootenay, 360,000 oz.; Boundary, 310,000 oz.; Nelson and Rossland, 180,000 oz.; Lardeau, 70,000 oz.; and the Coast, 125,000 oz. It is not unlikely the revised returns will show a somewhat larger production than has been estimated, but the foregoing figures represent what at present seems to be the position. The average price of silver for 1911 was a fraction lower than in 1910. The two closing months of 1911, however, saw a rise to an average of 55.312c., with a prospect of a further advance. If a higher average price shall be maintained throughout the ensuing year, and production in the province be increased to the extent it now gives promise of being, the figures, for both quantity and value, should be higher for 1912 than for any other year since 1901, which had a production of 5,151,000 oz., valued at £2,885,000, and was second only to the record year, 1897, with its output of 5,473,000 oz., valued at \$3,273,000. The mines that produced the silver in considerable quantity were as follows: In the interior parts of Sloean district, the Rambler-Cariboo, Richmond-Eureka, and Ruth-Hope; and in the Sloean Lake section, the Van Roi, Hewitt (Silverton Mines, Ltd.), and Standard. More than one-half of the production of East Kootenay was from the Sullivan mine, and in excess of one-third from the St. Eugene. In Nelson division the Molly Gibson, and at Rossland the Centre Star group, Le Roi, and Le Roi No. 2 company's group, made the output of those regions respectively. In Boundary district the mines of the Granby and British Columbia Copper companies contributed most of the silver from that part, while in Lardeau the Silver Cup, and on the Coast the Britannia, Marble Bay, and the Portland Canal Mining Co.'s mine each added its share. The Skeena country may be expected to add to the province's production of silver after railway transportation facilities, now being provided, shall be available; meanwhile, in that district a number of mineral claims on which silver-bearing ore has been found are being prospected, and some of them developed. Other Portland canal properties, too, are among the probable producers of the early future.

Quicksilver Production of California

By W. H. STORMS

Contrary to predictions generally made at the end of the year, the quicksilver output for 1911 shows a considerable increase over that of 1910. The production for 1911 was 19,109 flasks, valued at \$879,205 (flasks of 75 lb. valued at \$46.01 per flask, which was the average price for the year received in the San Francisco market). This is an increase in quantity of 1444 flasks, and in value of \$80,203, over 1910. The largest production came from San Benito county, followed by Santa Clara, Lake, San Luis Obispo, Napa, Sonoma, Santa Barbara, Trinity, and Colusa counties, in the order named. The following counties also contain quicksilver deposits, some of which promise to become producers at an early date: Kings, Monterey, Eldorado, Fresno, Shasta, Solano, Stanislaus, and Yolo.

Unusual activity has been apparent among operators and owners of quicksilver mines during the past year, and at the present time the outlook for a further increase in the 1912 production is favorable. During the past twelve months a 15-ton furnace has been built in Lake county; work on a 20-ton furnace in San Benito county has been started, and a 24-ton furnace has been completed in Sonoma county; in addition to the reduction plants already in operation in those counties. New furnaces of 24 to 40 tons capacity, respectively, have also been erected in Monterey and Fresno counties. The value of the 1911 quicksilver production has not been exceeded since 1905, when the product was sold for \$886,081. The output was valued at \$712,334 in 1906; \$663,178 in 1907; \$763,520 in 1908; \$773,788 in 1909, and \$799,002 in 1910.

Magmatic Origin of Ore-Forming Solutions

By C. F. TOLMAN

The recent review¹ by A. C. Lawson of 'Types of Ore Deposits' is chiefly interesting for the attack it contains on the widely accepted theorem that magmatic waters are important factors in ore genesis. The use of such statements, for instance, as that the author of one of the contributions appearing in the book reviewed, "is smitten with the juvenile water adliction", or that "the doctrine of magmatic waters" is "one of the fashionable vagaries of the present time", does not constitute an effective attack on the theory mentioned, but it is somewhat effective in arousing a reply. The objections, either directly stated or inferred, however, should be promptly met, and the high geological authority of the writer of the review mentioned, justifies a reopening of a discussion of certain points that otherwise might well have been considered to be closed.

Surely a brief suggestion of the varied phenomena that are believed to indicate magmatic origin of ore solutions is demanded by such statements as that "there is as yet no equally clear proof of the deposition of ores by magmatic waters" (equal to the proof that the lead-zinc deposits of the Ozark region and of Wisconsin are deposited from vadose circulation). Further, Mr. Lawson's intimation that the theory of magmatic origin of ores is founded on the evidence present in contact deposits only, is not a statement to be expected from one versed in the literature of ore deposits.

I contemplate presenting, at some future time, a summary of the critical data bearing on ore genesis, but in view of the need of an immediate reply to his review, I have attempted to present here a few of the more important lines of observation and reasoning, the accumulation of which has gradually forced the recognition of the rôle of magmatic waters as metallizing agents. Citation will be confined to ore deposits with which all American students are familiar.

Mr. Lawson's first criticism is inferred from his statement that J. F. Kemp "fails to make any distinction between (1) purely thermal metamorphism wherein the changes in rocks adjacent to an intrusive mass are due to molecular mobility induced by heat alone, and (2) reactionary metamorphism wherein the changes are due to reaction between the encasing rock and the materials emanating from the intruding mass." This is hardly justice to Kemp, for it is difficult to believe that any geologist who has worked on Western contact deposits does not recognize that contact action is erratic; and that at times the intrusive is practically anhydrous (as far as escaping vapors are concerned), and at other contacts these are most abundantly developed. (For further discussion of this, see under Lawson's third objection.) Recrystallization of rock by contact action without addition of material is abundantly proved. The conclusion is evident that either little or no water was present at the time of the intrusion, or that but little mineral matter was dissolved in the water vapors. On the other hand, to one familiar with the change of massive pure limestone into an epidote-garnet-diopside-magnetite-pyrite rock, at its contact with certain granitic intrusions of Arizona and New Mexico, the chemical analyses and calculations of Kemp, proving additions from the magma, appear as but an accurate statement of facts self-evident from field studies.

As a second objection, Lawson finds evidence against ore deposition by magmatic waters in the occurrence of ore later than the intrusive (and contact action). If the contemporaneous intergrowth of the contact minerals with the sulphides, pyrite, chalcopyrite, galena, and blende, proves that the metals are given off with the first vapors, it would indeed be extraordinary if these vapors always ceased with the congelation of the outer crust of the magma.

It is abundantly proved, by field evidence mentioned later, that the progressive cooling, solidification, and expulsion of ore solutions is registered in the gradual change in mineral groups deposited by the waters in the overlying rocks.

The third, and greater, difficulty is discovered by Lawson in the fact that only a small proportion of the contacts develop ore. This objection has also been urged by F. L. Ransome² in the following words: "If magmatic emanations alone were concerned in the deposition of most ore-bodies, it is difficult to understand why the deposition of ores should not be the regular and invariable accompaniment of the intrusion of certain magmas rather than the somewhat erratic and exceptional occurrences that they actually are." Suggestive evidence regarding this point may be obtained from a discussion of Lawson's idea that the intrusion induces an intensified (both chemically and thermally) circulation of the ground-water, which dissolves the precious and base metals from the rocks through which it passes, and deposits them, first, exactly at the contact between the molten rock and the older strata, and then later, after the adjacent portion of the intrusive is cooled, a more extended circulation mineralizes both the intrusive and intruded rock. Since the ground-water is everywhere present, such an active circulation should be set up around every intrusion. Since iron, magnesium, and the other elements are always present, the intensified circulation should contain these and develop at every contact garnet, diopside, epidote, etc. The rarer metals, such as gold and copper, are more sparingly distributed, and might therefore present some irregularity in their occurrence in the contact zones.

Under the magmatic theory, this difficulty vanishes, for, as already suggested, the intrusives differ greatly in their water content. An intrusion undersaturated with vapors and gases develops a contact action shown by the merest trace of recrystallization of the intruded sediments, while other intrusives, supersaturated with vapors at the time of initial crystallization, produce the profound changes at Morenci and Silverbell, Arizona, and numerous other places. An interesting case has recently been described in detail³ where the magma was nearly anhydrous on first intrusion, contact action producing only a recrystallization of the rock, but as the recrystallization proceeded, vapors were driven off from below, strongly pneumatolytic in action, and adding to the intruded beds very large amounts of iron and considerable lead, zinc, manganese, chlorine, fluorine, and other elements.

The way the magmatic theory meets the fact that ore deposition is erratically distributed around contacts may be summarized as follows: intrusives, especially acid intrusives, when undersaturated in respect to water and other vapors, develop thermal metamorphism only, accomplishing only a recrystallization of the adjacent rock. Occasionally they are supersaturated at the time of their intrusion, and then produce various effects depending upon the amount of vapor and its chemical composition. During further crystallization of the rock, the water content is driven off, either continuously or at critical points during the recrystallization, and in the majority of cases produces veins in the outer margin of the intrusive and in the adjacent rocks. These are ore veins only when the magma contains valuable metals. Deeply eroded intrusives have lost the outer zone of metallization and vein deposition. Examples of this are known; for instance, the deeply eroded Archean granites are often barren of every kind of vein.

As an introduction to the attempt to present some of the data on which are founded the modern ideas of the rôle of juvenile waters in ore deposition, ore deposition may be

²*Econ. Geol.*, Vol. VI (1911), p. 326.

³'Die Kontaktmetamorphose in Kristianlageblet,' Goldschmidt. See *Econ. Geol.*, Vol. VI, p. 707.

considered briefly as a product of rock differentiation, and since interest here centres chiefly in epigenetic deposits formed by ore solutions, rock differentiates may be classified with special regard to their water content.

Under anhydrous differentiates (this term always being used in a relative sense) may be grouped the recognized segregations of iron ores, chromite, platinum, iron sulphides, and probably other sulphides, at the margin of a basic intrusion. Such a basic differentiation may be termed an *in situ* marginal differentiation. The basic minerals crystallize first, and so any vaporous matter in solution in the magma will tend to concentrate in the still liquid acid portion. Therefore the complement of a basic segregation is an acid rock, enriched in respect to water content. Confining the following discussion, for brevity, to the suggestion of only one example of each type of ore deposit or ore process, I may cite as an example of marginal, *in situ*, basic differentiation, the corundum-bearing deposits of Corundum Hill, North Carolina.

Satellite dikes, the extruded products of an underlying differentiation reservoir, may be ore bearing, and, if this ore is original, it may be classified as a direct differentiation product. The basic ore dikes are generally anhydrous, while the acid dikes often show evidence of containing both water-vapors and mineralizers. The ilmenite-hypersthene-labradorite dikes, in places largely ilmenite with spinel and apatite, of Ekersund-Sogndal, Norway, also accompanied by purer lenses of ilmenite and both occurring in a 1200 square kilometre intrusive *massif* of norite and anorthosite, is a proved example of later dike differentiation of the basic type. Basic rocks may not, however, be entirely free from vapors. A gabbro may, for instance, develop seapolite-magnetite-apatite-specularite veins along its margin, the mineralogy of the veins showing the presence of water and chlorine vapors. If, therefore, a basic rock undergoes further differentiation, it may produce a small portion of acid rock, and finally expel a mineralized water solution. I believe that the evidence now collected is sufficient to prove that the silver veins at Cobalt, Ontario, are the final product of such a process, the intermediate product being the veins, lenses, and bunches of soda pegmatite, which have segregated out from the extensive Keweenawan diabase.

The acid series from pegmatites to quartz veins illustrates especially magmatic ore processes. I believe that geologists are generally agreed that pegmatite is a mixed rock-and-water solution, and that it is the product of acid differentiation of a magma. The minerals, such as tourmaline, topaz, apatite, fluorite, etc., suggest that such gases as boron, fluorine, and chlorine are generally present. Further, the fact that these minerals of the pegmatites are widely distributed throughout the granites, although in small amounts, indicates that all the vapors are not expelled by the crystallization of such a mass. Numerous substantiated instances of pegmatites grading into quartz veins by the failure of the feldspar, link these deposits together genetically. To cite one of many, take the noted pegmatites of the Black Hills, South Dakota. The list of minerals in these pegmatites includes: spodumene in gigantic crystals, albite, microcline, quartz, black and white micas, beryl, tantalite, columbite, ilmenite, amblygonite, lithiophyllite, tourmaline, garnet, apatite, dufrenite, and graphite, with the following sulphides: pyrite, chalcopyrite, leucopyrite; and the oxides, cassiterite and wolframite. The related quartz lenses and veins present a simpler mineralogical group, namely: quartz, tourmaline, garnet, cassiterite, wolframite, some scheelite, and pyrite. Here there is no question as to the genetic relation between the pegmatites and quartz lenses and veins.

Pegmatites occasionally develop the same intense alteration of adjacent country rock as is found along the tin-tourmaline-topaz, etc., veins, an alteration almost certainly due to the attack of the wall rock by the heated vapors from the veins.¹ I have seen samples showing intense greisenization along the wolframite-bearing pegmatites of

Mohave county, Arizona; and the wolframite deposits of the Whetstone mountains, Cochise county, Arizona, may be cited as a connecting link between pegmatites and quartz veins in greissen zones. In this locality an acid granite fingers out into pegmatite dikes intruding a fragment of Pinal schist. These dikes lose feldspar gradually, and become massive quartz veinlets. Along each veinlet the country rock is altered into greissen which contains the disseminated wolframite, the latter only occasionally appearing in the quartz veins and pegmatites. The cassiterite-tourmaline-topaz-quartz-fluorite veins, although they can thus be traced back directly to pegmatites, show independent evidence of direct magmatic origin, in their position only at or near the margins of granitic intrusives. Accepting this interpretation of magmatic origin, it may be extended to a continuous series of deposits in regions of granitic intrusion. The phases around the granitic bosses of Cornwall and Devonshire, Great Britain, are classified according to Findlay, as follows (the numbers show the order in which the minerals are deposited in the veins, suggesting a progressive and continuous change in the character of the ore-depositing solutions):

A. Tin-tungsten phase: (1) Apatite, (2) magnetite, (3) cassiterite and tourmaline, (4) wolframite, (5) arsenopyrite, scheelite, and fluorspar.

B. Copper phase: (1) Pyrite, (2) pyrrhotite, (3) chalcopyrite, (4) arsenopyrite.

C. Zinc-lead phase: (1) Chalcopyrite, (2) fluorite, (3) blende, (4) galena (barite with both the last).

More complicated series containing bismuth, cobalt, nickel, arsenic, uranium, radium, copper, zinc, lead, manganese, etc., minerals, are developed as later products of tourmaline granite intrusions of Bohemia and Austria.

With these series of deposits so well described and understood, it is difficult to understand the reluctance to assign ore deposits of a single phase to the neighboring granite intrusive. The Mother Lode-Alaska Treadwell type of deposits are characterized by an intense alteration along the walls, developing sericite, pyrite, calcite, dolomite, and in basic rock, epidote. The vein material is chiefly quartz with fluid inclusions, and albite, and tourmaline and zircon are present in both gangue and walls more occasionally. The presence in many veins of molybdenite, arsenopyrite, pyrite, chalcopyrite, sphalerite, and galena, line them up with certain phases of European veins. Other evidence fully as important as that shown by mineral association will be considered later.

A brief review of ore deposits formed around Mesozoic-early Tertiary granite, quartz-monzonite, and quartz diorite intrusions of Arizona and New Mexico furnishes proof from petrographical, geological, and structural relations. Much of the evidence to be summarized should be public property, as it has been presented in the detailed studies of the U. S. Geological Survey regarding Arizona and Utah deposits, and in the general description of New Mexico deposits. A belt of structural weakness, characterized by faulting, intrusion, and metallization extends diagonally across Arizona, from northwest to southeast, margining the massive great plateau of Arizona and New Mexico, and swinging around the southern point of the plateau near the Arizona-New Mexico line, it trends first northeasterly and then nearly northerly into Colorado. Excluding the later ore deposits in effusive rocks, which are considered below, the copper, lead, zinc, and gold deposits are grouped around or in small laccolitic or boss-like intrusions of acid or intermediate rock, intruded during the latter part of the Mesozoic or the early part of the Tertiary. Only two hypotheses are applicable to these deposits. Either (1) they are formed by metallizing vapors and water circulation direct from the magma, or (2) by the ground-water incited to unusual activity by the intrusions of the laccoliths, or of course by a combination of the two. The important data exhibited in this metallo-genetic province will be tabulated, although it involves some repetition of the points already mentioned.

(1) Many areas had suffered repeated intrusion before the entrance of the Mesozoic-Tertiary granitic rocks. For

¹On this subject see Spurr, 'Theory of Ore Deposition,' *Econ. Geol.*, March, 1908.

instance, in the Globe region, repeated pre-Cambrian intrusions similar in mineralogical composition to the later granite rocks, were not able to develop mineralizing action, and the ground-water in their neighborhood remained inactive in respect to mineralizing action. In other cases a relatively feeble metallization, of different type from that about the later intrusives, was induced. In certain areas, especially around Globe, Ray, and in the Catalina mountains, an early Mesozoic intrusion of diabase (former observations to the contrary notwithstanding) developed no metallization, although these became, in cases, the locus of mineralization, after the granites were intruded.

(2) Many of the Mesozoic-early Tertiary intrusives themselves were unaccompanied by metallization.

(3) The minerally active intrusives, as a rule, develop metallization only in certain restricted areas, and not along their entire periphery. For instance, ore deposits are especially localized at two places around the Morenci laccolith, at Morenci and at Metcalf. It is further noteworthy that at these two points the rock is more acid than in the rest of the laccolith. A still more curious concentration of ore solutions occurs at Globe. In the Globe hills all the deposits of proved economic worth are developed along the Old Dominion complex fault-zone of adjacent parallel faults. Hundreds of other faults were developed at the same time, but the Old Dominion system caught practically all the metallizing waters. I believe that the ore solutions were furnished by the Schultze granite of Mesozoic or early Tertiary age, which also developed the Miami-Inspiration ore zone along its southwest contact with the Pinal schists. On the northeast, however, the ore solutions were drained by this one complex fault-zone. A curious distribution of the ground-water, indeed, must be assumed to account for its great concentration along this one fissure zone.

Four phases of deposition can be recognized, binding the induced products of ore deposition into one related family. (For brevity, attention is confined to copper deposits, and in order to use only better known examples, Utah and California examples of this same group will be mentioned.)

PHASES OF CUPRIFEROUS METALLIZATION AROUND ACID AND INTERMEDIATE INTRUSIVES OF SOUTHWESTERN UNITED STATES, OF LATE MESOZOIC AND EARLY TERTIARY AGE.

Phase I. Developed during the solidification of the outer portion of the magma. Contact zones.

The mineralization is developed directly at the contact of the intrusive with calcareous rocks. Ores are pyrite, cupriferous pyrite, chalcopyrite, blende, and galena, intergrown with the iron oxides, magnetite and specularite, and the lime silicates, such as garnet, epidote, diopside, tremolite, actinolite, wollastonite, etc. A continuation of the process often develops later veinlets of sulphides in the contact rock. The Morenci garnet zones in the margin of fractured limestone blocks at the contact with the laccolith or the network of dikes from the same, has received the best description, but many more extensive examples are known.

Phase II. Developed during or shortly after the solidification of the outer portion of the magma.

Veins and lenses carrying contact minerals close to the intrusive, but not at the contact.

Examples of veins: Twin Buttes, Pima county, Arizona. The veins extend several hundred feet from the contact, carrying garnet, magnetite, hematite, and pyroxene (hedenbergite?) intergrown with pyrite and chalcopyrite.

Example of lenses: Yerington, Nevada. These develop lenses of typical contact ore at considerable distance from the intrusive.

Phase III. Developed shortly after the solidification of the outer portion of the intrusive.

These are pyritic lenses in the outer fractured portion of the intrusive. Example: Shasta county, California, copper deposits.

Phase IV. Hydrothermal 'after-effect' deposits: (A) in the intrusive; (B) in the adjacent rock.

- (A) (1) Veins with pneumatolytic characteristics. Example, Cactus vein, Nevada. This is in a shear-zone in a monzonite intrusive which also develops metallization at its margin. The veins show successive cooling of the solutions; the order of mineral deposition being (1) tourmaline, (2) quartz, (3) anhydrite, specularite, and siderite.
- (2) Quartz magnetite with lenses of chalcopyrite. Example, Old Baldy veins, Santa Rita mountains, Arizona.
- (3) Deposits accompanied by sericitization and silicification of the country rock. Examples, Morenci, Arizona, veins, and Bingham, Utah, disseminations.
- (B) (In the adjacent rock.)
- (1) Lenses in the limestone, unaccompanied by intergrowth of contact minerals, and at some distance from the intrusive. Example, Bisbee, Arizona.
- (2) Cupriferous dissemination in schists. Example, Ray, Arizona.
- (3) Quartz chalcopyrite veins at some distance from the intrusive. Example, Gibson lodes south of Globe, Arizona.

The above list is, of course, not complete, but is suggestive, and indicates a 'consanguinity' of the deposits developed around these intrusive masses of this age. The mere enumeration of the phases is not a proof of their magmatic origin, but emphasizes that ore deposition of this type is a continuous and complex process. Around any intrusion certain of the phases may be suppressed, and we may get, for instance, a two-phase deposition of, say, contact deposits and veins accompanied by sericitization. In no one case known are all the phases mentioned present.

In cases where the igneous forces found relief by one intrusion, and the later dikes are lacking, we can conclude that ore deposition was started immediately after the intrusion (if contact deposits are present), and continued during an unknown time thereafter. More definite evidence is available when satellitic dikes are present. Detailed study of certain areas has brought out the more definite evidence as to age and genesis desired. Take, for example, the Shasta county copper deposits. According to L. C. Graton, the history has been one of intrusion from a magma reservoir below, differentiation, and metallization the order of which is given as follows:

- (1) The intrusion of an alaskite porphyry and the brecciation of its marginal portions shortly after the intrusion.
- (2) Intrusion of a quartz-diorite mass.
- (3) Intrusion of basic dikes.
- (4) The deposition of great masses of pyrite carrying copper.
- (5) Cutting of the pyrite lenses by quartz-chalcopyrite gold veins.

The important point is that the quartz veins are closely related to pegmatite dikes, and as these are undoubtedly the last phases of igneous intrusion, ore deposition is confined to the period of igneous activity.

It is the working out of the details of individual cases of intrusion, differentiation, and metallization that has brought forward the magmatic theory of ore deposition and proved it to the satisfaction of many field geologists who have worked in these areas.

The more important deposits of this class in Arizona have had a simple history, and although examples are known in this region to me, where progressive differentiation has taken place, the last products of which already cut the ores, a better known example is the complicated ore deposits of Rossland, British Columbia. Here the critical history of intrusion, differentiation, and metallization is as follows:

- (1) Carboniferous strata were shattered by a large laccolitic intrusion of monzonite, accompanied by a complex of related dikes.
- (2) Ore deposition followed in the following three phases: (a) as typical contact deposits; (b) in veins under high

temperature, the group of minerals including biotite, hornblende, tourmaline, quartz, calcite, pyrrhotite, pyrite, chalcopyrite, gold, with the alteration minerals chlorite, epidote, and titanite; (c) hydrothermal disseminations in the monzonite.

(3) Satellitic lamprophyric dikes cut the ore deposits.

A second great group of ore deposits of Western America is designated as metallization induced within and by superficial volcanic extravasations of late Tertiary or Quaternary age, or by intrusives into these surface flows, under conditions of light load. A consideration of the various field relations that prove the close connection between metallization and vulcanism would extend this paper further than desired. It is difficult to understand how anyone who has read the report by Waldemar Lindgren and F. L. Ransome on Cripple Creek, Colorado, can fail to appreciate that here ore deposition is a late phase of vulcanism. J. E. Spurr's work proves that a series of vein formations often occur in this class of deposits that differ from each other widely in mineral content, and follow definite periods of volcanic eruption. It seems probable that detailed field work will permit defining accurately many of these strikingly different veins in the volcanic history of the region. (Such, for example, as the early massive calcite veins, and the later quartz-adularia-gold mineralization that replaces the calcite and sometimes invades separate fissures, of the River range, Mojave county, Arizona.) Finally, Le Croix has shown that almost all of the minerals found in ore deposits are formed by fumarolic action in volcanic vents. It follows that the theory that these veins were formed by waters furnished by volcanic outburst is as well established as the magmatic source of the ore deposits in the case of the earlier granitic intrusions.

As a final example, and a suggestion of the accumulation of evidence gradually gathered during the progress of the examination of a great metallo-genetic province, I will cite the extensive group of sericitic-pyritic gold quartz veins extending more or less continuously from California to Alaska. In the early studies, little evidence was recognized that metallization was the result of igneous intrusion. The veins were found to be either in the granitic batholith, in the greenstone or their equivalent schists, or in the slates and other sedimentary rocks at considerable distance from the granite. The 'Bed Rock Complex' is here composed of two series of rocks, interstratified with immense amounts of basic and andesitic effusives and probably basic intrusives. The gold veins can by no means be connected with the volcanic activity that produced the greenstones, although often found in them, nor with the metamorphism of these volcanics into schists, for both these (extrusion and metamorphism) took place before the intrusion of the granite batholith, while the veins followed the latter.

The subsequent intrusion of the batholithic complex of granite, quartz diorite, and quartz monzonite, may be described as a slow pulsating advance of molten rock, the intrusion of which may have occupied an entire geological period or more. The earlier members were solidified and in places transformed into gneisses before the last of the igneous masses were intruded. In some areas (the Mother Lode region, for instance) differentiation split off basic diorites and gabbros. Contemporaneous and later dikes, both of like composition to the batholith, and of acid and basic differentiates, were intruded. The composite batholith and later dikes are oriented in accordance with the structure produced by pressure antedating the intrusion and expressed by close folding of the earlier rocks and by schistosity. The ore deposits occupy a similar oriented series of fractures, often following the dikes.⁵ More accurate dating of the metallization is possible as later basic dikes are occasionally found cutting the veins (Juncos peninsula), showing that the final rock solutions were extruded after some of the ore solutions.

Not less remarkable than the continental extent and homo-

geneous composition of this linear intrusion, is the fact that the composition of the solutions forming the gold ores was practically the same along the entire length of the batholith. This raises difficulties for those who would explain the deposits as the result of a diffuse descending and concentrated ascending meteoric circulation. They must explain how the solutions traversing the various belts of rocks, and depositing their load in rocks of different composition, attained such a uniform chemical composition. The mineralogy of the deposits has been mentioned before. The intense sericitization and pyritization of the wall rock with the development of carbonates and epidote, indicate an unusual reactivity of the alkaline bicarbonate solutions that caused this action, and tourmaline, albite, rutile, and molybdenite indicate granitic origin, if the evidence of other regions is accepted regarding the genesis of these minerals.

In the foregoing discussion, the evidence for magmatic origin of ore deposits has been drawn from field evidence and mineralogical association. The data that have gradually driven out the idea of the importance of meteoric circulations in ore formation are not theoretical. The hypothesis has, however, not yet reached its proper position, as it has had a severe fight to replace the theory entrenched by Van Hise's masterly presentation. Here only those deposits where the intrusive is directly at hand have been assigned a magmatic origin. Even where the mineral association in the ore deposit suggests the presence of an underlying intrusive, the field geologist has rarely had the courage of his conviction to suggest the presence of such.

From the theoretical side, however, the magmatic idea has the advantage over the hypothetical concentration by meteoric waters. The established cases of concentration by the latter rarely attain a concentration of more than 10 to 1. In disseminated copper ores the enrichment may be taken as raising the value of an original $\frac{1}{2}$ to $1\frac{1}{2}\%$ ore to a 2 to 5% ore. In Butte, where the action has been long continued, under favorable conditions, we may take 2% as the average of the original ore, enriched in places to a 60% ore, but on the average to about a 5% ore. The concentration by vadose circulation of the Lake Superior iron ores is probably less than this on the average. Further, the chemical action involved in this well known process consists of oxidation, solution, and immediate precipitation at the water-level by pyrite or other reducers. The chemistry of a dispersed deep-seated meteoric circulation is not understood, and the very existence of such circulations, except under artesian conditions, is doubtful. Further, active precipitants are everywhere present, and even kaolin and crushed rock are effective precipitating agents in zones below the level of oxidation, so that doubt is raised as to whether the metals could remain in solution long enough, in a dispersed circulation, to raise the concentration of the ore solutions to the degree demanded by the deposits of the precious metals.

On the other hand, in a cooling magma the crystallization of the common minerals takes with them chiefly those less common bases that can form mixed crystals, double salts, or chemically replace the more common elements of the rock minerals. When crystallization reaches the point of forcing out the residual water, it will contain the less common substances, especially those soluble in the water or volatile at the temperature of the solidification of the magma. Crystallization and melting may take place a number of times. The process seems competent to produce the degree of concentration (more than a million to one in the precious-metal deposits) demanded. The exceptional and erratic distribution of such deposits is explained by the exceptional and erratic concentration of such solutions, and the chance of their reaching the channels of escape.

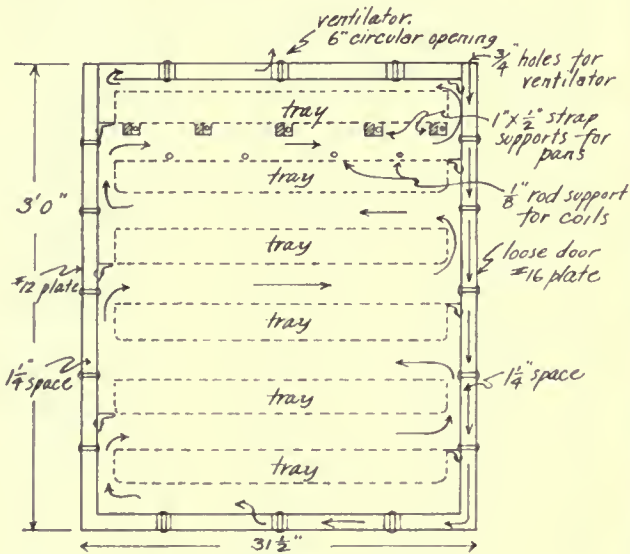

It is hoped that the above discussion, incomplete as it is, suggestive rather than detailed, is sufficient to show that the theory of the magmatic source of ore solutions is now firmly founded on field evidence. That, though it now dominates speculation regarding ore genesis, it is not a "prevailing obsession," and not to be set aside in such a summary manner; nor is it founded on such slender ground of geological fact as Lawson would have us believe.

⁵Field proof that these dikes belong to the intrusive cycle, and not to recent basaltic effusive cycle, is to be desired.

An Electrical Drier for Zinc Precipitate

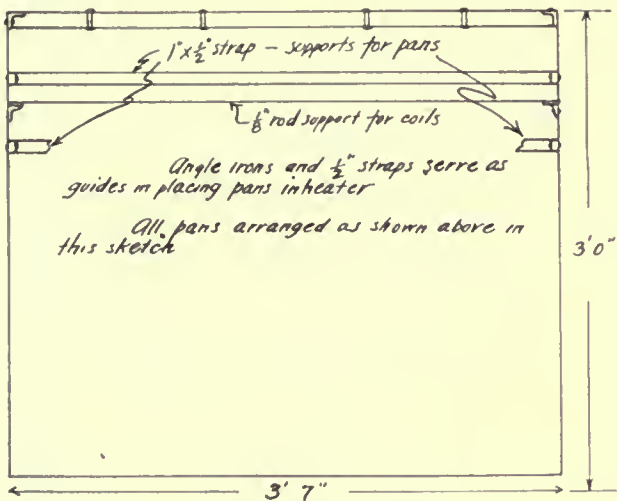

By DONALD F. IRVIN

The preparation of zinc precipitate for smelting involves a preliminary drying, although if roasting is not desired, it is customary to charge the precipitate into the crucible with a higher moisture content than formerly practised. Drying is done in various ways by direct heating, as in a coal-fired oven; or in a steam-bottom pan; or electrically. Some

TRANSVERSE SECTION.

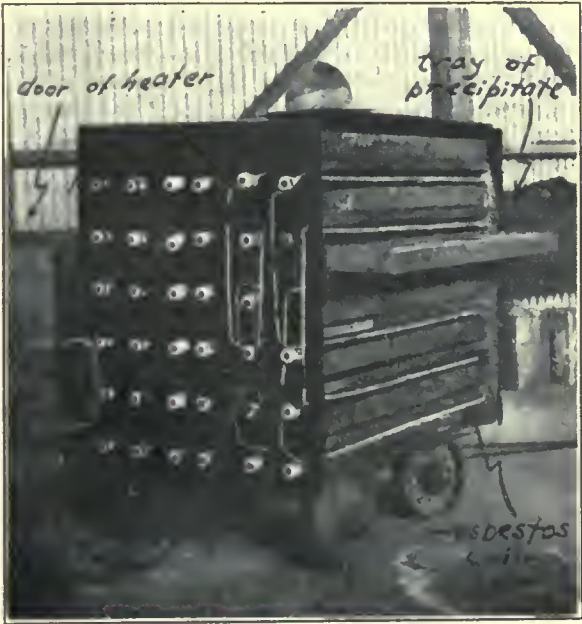

features of the last method are that drying may be carried on without the dirt caused by stoking a furnace, and also with the minimum attention in the way of regulating the heat. Furthermore, heating can be carried on safely at night, when attendants are usually off duty, a consideration of some value when melting is done on day-shift only.

LONGITUDINAL SECTION.

Thus, a small drying device does the work of one of twice the capacity, requiring constant watching. A most satisfactory electric drier is that installed for the El Tigre Mining Co. by D. L. H. Forbes. It consists of a series of sheet-iron trays, enclosed in a ventilated sheet-iron cage, the whole mounted upon wheels for ease of movement. The accompanying illustration and sketches show the construction and wiring of the heater, which is simple and effective. This drier is used for the precipitate gotten from Merrill zinc-dust precipitation presses, and no especial care is required in manipulation, save that time is gained by partly air-drying the precipitate before removing from the presses. Condensation of the rising steam occurs on the inner side of top, making contents of top tray damp through dripping. The remedy for this is more ventilation, which

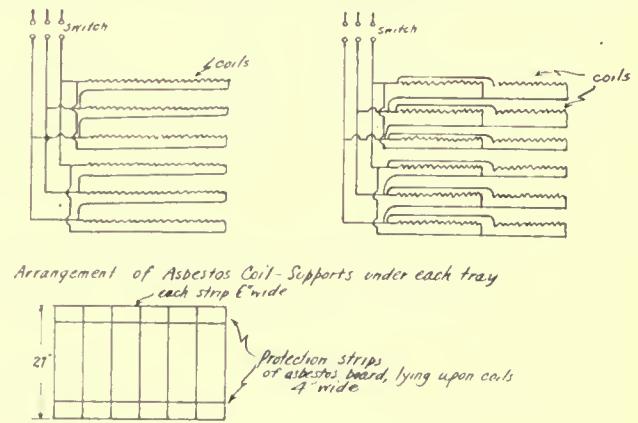

must be balanced against undue loss of heat thereby. The heating current is supplied from the regular 110-volt electric lighting circuit, and the resistance is furnished by coils of No. 18 hard-drawn iron wire. There are 1620 ft. of wire per phase, and in all, 4860 ft. is used. Each phase serves two trays, and each tray has 8 coils. Thus, each coil is wound with a little more than 100 ft. of resistance wire. This requires 30 to 35 amperes current at 110 volts. The capacity of this drier is about 175 kg. of precipitate, dried

ELECTRIC PRECIPITATE DRIER.

from the usual damp condition of fresh air-dried precipitate to absolute dryness in 24 hours.

Short-circuiting, resulting from the moist, dripping condition of the interior of the cage, is one feature to be guarded against. This may be prevented by smearing the coils with

WIRING DIAGRAM.

plaster of paris, thus protecting them from moisture. These wire coils are wound upon strips of asbestos board, 6 in. wide by 27 in. long, and 1/4 in. thick, being supported by small longitudinal rods of 1/8-in. iron, as shown in the sketches. When first built, this drier had glass tubing wound with asbestos wicking instead, but was soon changed to the present plan. This is a very handy machine and saves considerable in first cost over the construction and maintenance of a brick oven drier. A steam bottom pan is not feasible at El Tigre, as all motive power is now electric, and the former boiler room is several hundred yards from the melting house. Also, steam losses in operation would be high. Comparisons of operating cost with other methods of drying cannot include the highly desirable features of the electric drier making for convenience, cleanliness, and safety; all of which incline millmen in its favor, especially after having used one.

Cyanide Regeneration

By B. GEORGE NICHOLL

*With the introduction of the cyanide process it appeared that finality in gold-extraction processes had nearly been achieved, but the early application of the process to many ores was accompanied by such unsatisfactory results that eventually only those which contained no refractory elements were selected for cyanidation. In accumulated dumps the difficulty lies chiefly in the high consumption of cyanide, owing to the fact that other metals than gold generally go into solution readily, and the baser metals have sometimes to be fairly well leached out before the gold is attacked. This is particularly the case where copper is present in small quantities, and in the cyanidation of auro-cupriferous ores many variations of the cyanide process have been tried, mainly aiming at effecting a reduction in the chemical consumption. No plant operating on auro-cupriferous ores has yet overcome copper troubles, and so long as copper is readily soluble in a cyanide solution, in no such case will the initial consumption of cyanide be very materially reduced. The presence of copper in solution gives rise to precipitation difficulties, and these have so effectually resisted correction that precipitation on zinc-shavings had to be abandoned in favor of other methods. In the early operation of the process the only other form of precipitation practised was the Siemens & Halske electrical process, with precipitation-boxes about 4 by 8 by 30 ft., consisting of about six compartments, each 4 by 8 by 5 ft., and each compartment containing anodes of iron enclosed in hessian cloth and cathodes of lead-foil. The distance between anodes and cathodes was about 6 in., and a current density of 0.02 amperes per square foot of anode surface was generally employed. As low as this current density was, it was sufficient to cause the anodes to decompose rapidly, with consequent formation of ferro-cyanides and ultimate loss of cyanide during the passage of the solutions through the precipitation plant. The only advantage that the process offered over zinc precipitation was that more metal was recovered, and the solutions were returned to the vats in a fairly clean state. The chief difficulty, the high consumption of cyanide, had not been remedied; on the contrary, the cyanide consumption had slightly increased, and the advantages obtained scarcely compensated for the increase.

In 1903 a great improvement in electrical precipitation was effected by Charles Butters, of California. Butters used anodes of lead sheets peroxidized by electrolysis in a solution of permanganate of potassium, and sulphuric acid. These anodes resisted oxidation to a much greater degree than iron anodes, and withstood a current density of 0.5 amperes per square foot without apparent decomposition, and, owing to the use of a greater current density, the size of the precipitation plant was greatly reduced. Butters erected at Virginia City an electrical precipitation plant consisting of boxes 29 ft. long, 10 ft. wide, and 4 ft. deep, and with V-shaped bottoms. Each box had 12 compartments, and each compartment contained 18 anodes and 17 cathodes, spaced 1 in. apart. The anodes consisted of 0.185-in. lead plates, covered with lead peroxide, and not enclosed in any way. The cathodes were plates of ordinary commercial tinned steel, and fitted with an iron strip along the tops to keep them rigid and to connect them together. In using such a high-current density, the gold is precipitated as a pulverulent deposit on the tin, and is periodically wiped off, falling to the bottom of the box, where it remains until cleaned up. In the operation of the Butters plant a regeneration of cyanide was observed, and this was increased as the decomposition of anodes was reduced. It also increased with the increased precipitation of copper and the consequent liberation of cyanogen, which, in the presence of excessive alkali, reformed active gold solvents.

It was not, however, until this plant had been in operation for some time that the possibility of a recovery of much cyanide was fully appreciated, and, by carefully regulating current density, alkalinity, and other conditions, Butters was able to regenerate sufficient cyanide to defray the cost of running the precipitation plant.

In September 1905 a patent, entitled 'Method for recovering precious metals from solution,' was granted to Isaac Anderson and Michael Scanlan, metallurgical chemists, of Arizona. In this process it was claimed that the silver and gold could be precipitated in such a manner that the solution could be readily restored to its original activity with but little loss of the original solution and at a small cost for regeneration. This process is based upon the fact that when sulphuric acid is added to a cyanide solution of the precious metals in which sulphides and chlorides are present, the sulphuric acid so added will combine with the potassium of the potassium cyanide to decompose the double cyanides formed by the action of the potassium cyanide on the precious metals, and the metals freed from combination with the potassium cyanide will then combine the sulphur and chlorine present to form insoluble sulphides and chlorides, which will be precipitated, leaving the cyanogen in the liquid in the form of hydrocyanic acid, or in combination with the radicals with which the sulphur and chloride have been combined. The precious metals having been precipitated as chlorides or sulphides, the superabundant liquor can be decanted off, and the potassium cyanide may be regenerated by decomposing the potassium sulphate formed by the action of the sulphuric acid from the solution. The decomposition of the potassium sulphate and the removal of the sulphuric acid may be readily accomplished by introducing lime into the solution and decanting off the precipitated gold and silver, the lime so added causing the decomposition of the potassium sulphate with the formation of insoluble calcium sulphate and simultaneous regeneration of potassium cyanide. In the operation of this process it was claimed that a regeneration of 90% of cyanide could be effected. At the time of the introduction of this process there was little demand for the advantages which it offered, and there is no record of its operation on a working scale, except on the works controlled by the inventor, where, apparently, it was satisfactory.

In 1908 W. H. Wheelock, an American chemist, in experimenting with the action of sulphuric acid on cyanide solutions, practically rediscovered the process previously operated by Anderson, and contributed an article to the *Mining and Scientific Press* (December 18, 1909) setting forth the results of his experiments. After perusing Wheelock's article I then conducted a number of experiments at the works of the Mitchell's Creek Gold Recovery Co., Bodangora, N. S. W., on the lines laid down by Wheelock, and the following are the particulars of one of these tests: 160 lb. KCN solution containing 0.23% free cyanide, 1.5 lb. lime, and about 5 lb. copper per ton of solution was taken from the tops of the precipitation-boxes and put into a clean cyanide case for treatment. Sulphuric acid was then added (the solution being gently stirred during the addition of the acid) till a precipitate ceased to form. It took 2 lb. of acid to complete the reaction. After standing for two hours, a solution from 5 lb. of lime was added (the portion of lime that did not dissolve in water being discarded); lime solution was added only until the acidity was neutralized. After stirring and allowing the precipitate to settle, the solution was again tested for KCN and it was found to have risen to 0.695% or a gain in KCN of 10 lb. per ton of solution.

These results indicate that under careful manipulation the process of precipitation by sulphuric acid and regeneration of the cyanide is commercially possible when the following general conditions are observed: The solution to be treated should contain very little free cyanide, because if free cyanide be present a fair amount of acid will be consumed in neutralizing it before precipitation actually commences. This cyanide would be totally lost, and so would the acid used to neutralize it. The solution should be as nearly saturated with copper as possible: this can be ob-

*Abstract from *The Mining and Engineering Review*.

tained by passing the solution through successive vats until it will pick up no more metal. Acid should be added until the further addition of acid ceases to make the solution turbid. An excess of acid will prevent a good regeneration and cause a subsequently greater consumption of lime to restore alkalinity and regenerate the KCN. The precipitate formed on the addition of acid should be removed as quickly as possible from the solution and lime added before much HCN could have had time to escape.

Anderson claims that a regeneration of over 80% of the original cyanide can be obtained in the treatment of solutions carrying 0.5% of copper, and that the precipitate will contain 50% of copper; but, of course, the results must depend upon other conditions than only the amount of copper present.

At the Mitchell's Creek works several hundred tons of solution was profitably treated by acid regeneration, but lack of vat accommodation, the large amount of precipitate to handle, and the absence of conveniences to systematically continue this method placed it at a disadvantage when compared to improved electrical precipitation. The latter plant will operate continuously with very little attention, and with only a small power-cost; while facilities for acid regeneration would require large storage capacity for solutions and a special smelting plant to deal with the precipitate. On the same works an experimental electrical precipitation plant on the Butters principle was installed, and this plant consisted of a box 10 ft. long by 12 in. wide and 12 in. deep at the sides, and tapering to 18 in. deep in the middle, and containing eight compartments. About 120 sq. ft. of cathode surface was employed, and from 3 to 8 tons of solution passed through the box in 24 hours. The current density rate of flow and other conditions were occasionally varied, but the average of daily returns of this plant during about three months' run is given below:

	Top of box.	Tail of box.
Rate of Flow: Tons per 24 hr., 3.5.		
Au (dwts.)	1.6	0.4
Cu (lb. per ton)	4.68	3.83
KCN (%)	0.05	0.125
Current Density: Amperes per sq. ft. of anode surface, 0.5.		

This average is from the total returns recorded. During the trials two samples were taken daily, each sample being from a continuous siphon, and included in the returns are a number of samples taken while the current was off, and during which period a loss of cyanide was recorded. As a result of these experiments a large electrical precipitation plant was installed, but this has not been long enough in operation to furnish any valuable data. Since this plant started it has effected a regeneration of from $\frac{1}{2}$ to 2 lb. KCN per ton of solution treated, but better results than these are expected when the most suitable condition of the solutions for precipitation has been determined.

Since the installation of the above plant a patent has been granted for a method of electrical precipitation wherein rods of Acheson graphite, each $\frac{1}{2}$ in. by 24 in., are placed side by side to form a plate, and cathodes of corrugated or waterproofed felt or cardboard, which has been made superficially electrically conductive by treatment with an adhesive compound and Acheson graphite powder. Acheson graphite, by reason of its purity and high conductivity, will withstand a very high current density as an anode without injury, and the fine graphite is found to impart a highly conductive surface to the treated cardboard. Cathodes treated in this way cost about £10 per 5000 sq. ft., and this area is sufficient to obtain good precipitation from 200 tons of solution per 24 hours. The arrangement of electrodes in this plant is such that the greatest possible number of AuCN and CuCN molecules will be brought into contact with the cathodes during the passage of the solutions through the box. In electrical precipitation more depends on diffusion of the molecules than on variations of other conditions, and increasing the cathode area increases the percentage of precipitation more than does in-

creased current density, as decomposition of the metal-bearing molecules only occurs when they actually make contact with the cathode. By the use of anodes, consisting of round rods placed side by side to form a plate, and cathodes of finely corrugated, electrically conductive cardboard or waterproofed felt, the area of electrode surface in a box of given size is more than 100% greater, and the solutions in passing between the uneven surfaces of the electrodes will be more diffused and less liable to track than is the case where the electrodes are ordinary flat sheets. The cathodes require to be made sufficiently strong to prevent warping, and this can be done by running a wire around the sides and bottom, the ends of the wire being bent over so as to dip into the mercury grooves to make electrical contact. An additional advantage in having the cathodes corrugated is that the precipitated metal will not peel off and touch the anodes, causing short circuits. If the cathodes are quite rigid the distance between anodes and cathodes can be reduced to about $\frac{3}{8}$ in., the clearance required being only enough to prevent the accumulation of precipitate between the plates. The rods composing the anodes are fixed together firmly. Kerosene is poured into the box to form a layer about $\frac{1}{2}$ in. deep on the top of the solution, to prevent the accumulation of froth and the escape of hydrocyanic acid.

Precipitation and subsequent regeneration of KCN depends upon the fact that when the metal-bearing molecules in their passage through the box come in contact with the cathode they are immediately decomposed, the metal adhering to the cathode or falling to the bottom of the box, where it remains until the clean-up. The energy imparted to the liberated cyanogen is expended partly in forming compounds with free alkali, and partly in the decomposition of water and formation of hydrocyanic acid. Where the anode used has not a high resistance to oxidation, most of the liberated cyanogen would be lost in the formation of compounds with the anode material.

The total cost of a plant to treat 300 tons of solution per 24 hours would be about £500, the attention required would be negligible, and about 12 b.h.p. would be required to furnish the necessary current. A small recovery in cyanide and the higher extraction possible from cleaned solutions would soon return the cost of the plant. Attendance, power costs, and cathode renewals would not be as great as the cost of attendance, zinc, etc., in a zinc precipitation plant. In the former plant the copper also would be recovered.

In some cases it would appear to be an advantage to use a combination of zinc and electrical precipitation, the solutions passing first through the zinc-boxes, where the gold would be saved, the function of the electrical boxes being to purify and regenerate the solutions before returning them to the vats. On account of the difficulty in getting complete precipitation of the metals without excessive cathode surface in an electrical precipitation plant, a judicious combination of zinc and electrical precipitation in the cyanidation of base-euphriferous ores is almost certain to show greater economy than either method alone.

The latest process claiming to effect a saving in cyanide and a good extraction from raw sulphide or sulpho-telluride ores has recently been patented by J. C. Clancy and is now in operation at the 100-ton plant of the Ajax Gold Mining Co. at Victor, Colorado. This process depends upon the constant formation by electrolytic action of cyanogen iodide in the pulp during agitation. Mr. Clancy claims to have reduced the consumption of cyanide to mechanical loss only. I have conducted a number of experiments in accordance with Clancy's directions, but up to the present time the results have not been uniform, and trials of the process on a larger scale are now being carried out. In Australian mining at the present time more depends on the discovery of some process which will profitably extract the metals from poor sulphide ores than on the discovery of new mining fields, and the success of the Clancy process is greatly to be desired. Cooperation between metallurgists exploiting the electro-chemical processes would probably bring success where isolated experiments are certain to fail.

Combination Methods for Smelter Assays

By A. T. FRENCH

*The smelter chemist is called upon to do daily analyses of one or more ores or products which form the furnace charge, and also of the slag. The chief constituents commonly determined are, for the furnace charge: Insoluble (SiO_2), Fe, Al_2O_3 , CaO, Zn, Pb, S, and Cu; and for slags: Insoluble, Fe, Al_2O_3 , CaO, Zn, and Cu.

Many methods of determining the separate elements are given in text-books and in technical literature. It is my object to present a scheme for the combination of these methods which has been worked out by experiment, and which seems of sufficiently general application to merit the attention of others interested in similar work. The problem, then, is the separation of these elements and oxides from each other and their estimation in the presence of such usual constituents of ore as As, Sb, Mn, MgO, and others. A standard of accuracy of 0.5% is required (for example, iron, if reported 20%, must be within 19.75 and 20.25), except in the case of copper, which should be within 0.1 or 0.2% on ores and 0.025% on slags.

METHOD 'A' FOR ORES.—Weigh out two $\frac{1}{2}$ -gm. portions for the analysis and $\frac{1}{2}$ or 1 gm. for sulphur. The two $\frac{1}{2}$ -gm. portions for analysis are moistened with water, 5 to 10 c.c. of strong HNO_3 is added, and taken to dryness on the hot plate; 5 c.c. of HCl is added to each, and, after a few minutes' digestion at a moderate temperature, 20 c.c. of dilute H_2SO_4 (1:3), and the assays are rapidly boiled down to white fumes. After cooling and dilution with water to about 100 c.c., to (1) 5 c.c. of HCl is added, and to (2) 10 c.c. of dilute H_2SO_4 , and both are boiled a few minutes. In (1) insoluble, SiO_2 , Fe, CaO, and Zn are to be estimated. In (2) Pb, Cu, and Al_2O_3 .

(1) *Insoluble.*—The hot solution is filtered through an ashless paper and washed thoroughly with hot water, the filtrate is removed and the residue washed with a hot solution of ammonium acetate (if much lead is present it is better to wash back into the beaker, add ammonium acetate and digest for a few minutes on the hot plate, finally throwing back on the same filter); the washings are thrown away and the filter with contents is placed in a roasting dish, dried, ignited in the muffle, and, after cooling, weighed as insoluble.

The filtrate in a 600-c.c. beaker is diluted with hot water to 300 to 400 c.c., about 10 gm. of pure ammonium chloride added, and if manganese is present 10 to 20 c.c. of strong bromine water, then an excess of NH_4HO . The solution is brought to a boil, the precipitate allowed to settle, and then filtered, washing with hot water, or, better, if much zinc is present, with a hot dilute ammoniacal solution of ammonium chloride. The filtrate and washings are received in a litre beaker and the hydrate precipitated is re-dissolved in HCl and re-precipitated as before (not forgetting the bromine water, if necessary) in a rather smaller bulk, combining the two filtrates.

Iron.—The hydrate precipitate is either re-dissolved in dilute H_2SO_4 , the iron reduced and titrated cold with standard potassium permanganate, or the precipitate is dissolved in HCl, reduced, and titrated with standard potassium bichromate.

Lime.—To the combined filtrates 20 to 30 c.c. of a 2% solution of ammonium oxalate is added, the solution is brought to a boil and allowed to stand in a warm place for half-an-hour, by which time the calcium oxalate is filtered off, washed thoroughly, dissolved in warm dilute sulphuric acid, diluted with hot water, and titrated hot with standard potassium permanganate.

Zinc.—The filtrate from the calcium oxalate is acidified with HCl, adding 5 c.c. in excess. A current of H_2S is passed through it for 5 or 10 minutes, the solution is then

boiled for five minutes, filtered if necessary (usually this is not the case), cooled to about 30°C ., and titrated with standard potassium ferrocyanide.

(2) This portion is allowed to stand until quite cold in order that the lead sulphate may separate out and settle. It is then filtered, washing by decantation with cold water, and adding a little dilute H_2SO_4 to the wash-water from time to time.

Lead.—To the residue in the beaker is added 5 to 10 gm. of ammonium acetate, a little acetic acid, and 100 c.c. of hot water. The filter paper is dropped into it and the beaker placed on the hot plate, brought to a boil, and, when all the lead sulphate is dissolved, about another 100 c.c. of hot water is added, and the solution is titrated hot with standard ammonium molybdate.

The filtrate, to which a little strong HCl may be added, is heated to near boiling and a current of H_2S is passed for ten minutes. The sulphides are filtered off, using a rapid filter and washed with hot water (H_2S water should be used if the filtrate comes through at all cloudy, but this is rarely the case).

Copper.—The sulphides are washed back into the beaker, opening out the filter paper and placing it on the side of the beaker; a few drops of bromine water are poured over it to oxidize the traces of sulphides retained in the pores of the paper; then 5 c.c. of HNO_3 and a little hot water, and the paper is removed. A small quantity of iron is added, about 0.05 gm., the beaker is placed on the hot plate and boiled down to dryness. After cooling, 2 or 3 c.c. of HCl is added, and the copper estimated by the permanganate method.

Alumina.—A filtrate from the sulphides is boiled to expel H_2S , oxidized with 2 or 3 c.c. of HNO_3 , a slight excess of NH_4OH is added, and the solution boiled until it no longer smells of NH_4OH . After standing a minute or two to settle, the hydrates are filtered off, washed slightly, washed back into the beaker, and re-dissolved in a little HCl, pouring the acid first over the filter paper. The solution is just neutralized with NH_4OH , $2\frac{1}{2}$ to 2 c.c. of HCl is added, and the alumina is estimated by the phosphatase method.

Sulphur.—On siliceous and roasted ores, 1 gm. is taken, on pyritic ores $\frac{1}{2}$ gm., moistened with water, and about 5 gm. KClO_3 and 10 c.c. HNO_3 added. The assay is taken to near dryness on the hot plate, avoiding baking, taken up with 5 to 10 c.c. acetic acid (1:1) and 150 to 200 c.c. of hot water; about 10 gm. of ammonium acetate is added, the solution is brought to a boil, and titrated, boiling, with standard barium chloride.

Examination of insoluble silica.—(1) When the insoluble is white, as in treating most raw ores and others easily attacked by acids, the residue obtained in the first part of the analysis is fused in a platinum dish or crucible with ten times its weight of fusion mixture (K_2CO_3 and Na_2CO_3). The melt is dissolved in HCl, transferred to a porcelain capsule or casserole, taken to dryness on the hot plate, taken up with 5 to 10 c.c. HCl, diluted, and the silica filtered off, dried, and ignited. After cooling in a desiccator the SiO_2 is weighed and an addition made for the SiO_2 still left in solution. The filtrate from the SiO_2 is rendered slightly ammoniacal, the solution boiled until it no more smells of NH_4OH and, after standing a few minutes, the hydrates are filtered off, washing thoroughly with hot water. The filter and contents are dried, ignited, and weighed, reporting as Al_2O_3 and Fe_2O_3 .

(2) When the insoluble is black or red, as in treating roasted ores and substances not easily attacked by acids, the residue is fused as in (1) and the SiO_2 filtered off, ignited, and weighed.

The filtrate is tested for Cu and Pb by passing H_2S . If any is found, the sulphides should be filtered off, dissolved in HNO_3 , taken to fumes with H_2SO_4 , diluted, and cooled; the PbSO_4 is filtered off and added to the main portion and the copper in solution also added to the main portion obtained in the first part of the analysis, before precipitation with ammonium sulphocyanide. (The free sulphuric acid should be just neutralized with NH_4OH .)

The filtrate from the sulphides, or from the silica in

*Abstract from *Bulletin* of the Institution of Mining and Metallurgy.

absence of Cu and Pb, is boiled to expel H_2S , oxidized with HNO_3 , or $KClO_3$, and NH_4OH is added until the solution darkens, or, in absence of much iron, until the solution is only faintly acid, and 5 to 10 gm. of sodium acetate is added. The solution is brought to a boil, allowed to stand, and the precipitated basic acetates of iron and alumina are filtered off.

After washing with hot water the acetates are washed into a porcelain dish, about 1 in. of caustic soda or potash added, and digested at a gentle heat for a quarter of an hour. The Al_2O_3 goes into solution, the iron precipitate is filtered off, re-dissolved, reduced, and titrated as in the first part of the analysis.

The filtrate is acidified with HCl and the Al_2O_3 either estimated by the phosphate method or a slight excess of NH_4OH is added, boiled off, the precipitate filtered off, dried, ignited, and weighed as Al_2O_3 . (If the quantity of iron and alumina is large, the acetates should be dissolved in HCl and re-precipitated with NH_4OH , boiling off excess before extracting with caustic, but usually this can be omitted.)

Lime.—To the filtrate from the acetates about 10 c.c. of NH_4OH and 20 c.c. of a 2% solution of ammonium oxalate are added, and the calcium oxalate precipitated and filtered off. This precipitate is dried and ignited, weighing as CaO ; it should be tested for iron, and, if any is found, the weight of Fe_2O_3 is subtracted from the CaO , and the calculated amount of Fe added to that previously found.

Zinc.—The filtrate from the lime is acidified, gassed, boiled, cooled, and titrated with standard potassium ferrocyanide.

METHOD 'B' FOR SLAGS.—The sample should be chilled; this is usually done at the furnace, the molten sample of slag being poured into a bucket of water. Or the slag in lump form may be heated to redness in the muffle and thrown into water before grinding, the effect being to make the slag easily attacked by acids, anything up to 50% SiO_2 giving a white insoluble containing not more than 1 or 2% of substances other than silica. For the analysis, two $\frac{1}{2}$ -gm. portions are weighed into 300-c.c. beakers or casseroles. The slag is moistened with 2 or 3 c.c. of water, the beaker is held over a bunsen burner, keeping the contents in motion, and when near boiling, 3 c.c. of strong HCl is added and a few drops of HNO_3 . The heating is continued for 2 or 3 minutes, when gelatinous silica separates out and the beaker may be placed on the hot plate and taken to complete dryness.

Insoluble.—The two portions are taken up with 5 c.c. HCl diluted to about 100 c.c. with hot water, and the insoluble filtered off (use of the filter pump is unnecessary if the SiO_2 has been properly de-hydrated), dried, ignited in the muffle, and weighed.

Filtrate (1) is diluted to about 300 c.c. with hot water, about 10 gm. of NH_4Cl is added, and bromine water if manganese is present, and then NH_4OH in excess. The solution is boiled, the precipitate allowed to settle, then filtered into a litre beaker, washing with hot water, the hydrates are re-dissolved in HCl , NH_4Cl and bromine water (if necessary) added, re-precipitated with NH_4OH , and filtered off, combining the two filtrates.

Iron.—The hydrate precipitate is re-dissolved in dilute H_2SO_4 , reduced, and titrated with standard permanganate, or HCl may be used, and the solution, after reduction, titrated with bichromate.

Lime.—To the combined filtrates, which should be strongly ammoniacal, 20 c.c. of a 2% solution of ammonium oxalate is added, the solution brought to a boil, and allowed to stand in a warm place until the calcium oxalate settles. This is then filtered off, washed, dissolved in dilute H_2SO_4 , and titrated hot with standard permanganate.

Zinc.—The filtrate from the lime is acidified with HCl , adding 5 c.c. in excess, a current of H_2S is passed for 5 to 10 minutes, and the solution is boiled, cooled to about 30° C., and titrated with standard potassium ferrocyanide.

Alumina.—Filtrate (2) is just neutralized with NH_4OH , 2 or 3 c.c. of HCl is added, and the alumina estimated by the phosphate method. If much Cu and Pb are present the filtrate should be gassed, filtered, H_2S boiled off, and the solution oxidized before proceeding as above; but I have

not found this to be commonly necessary in dealing with ordinary slags.

Copper.—For copper, 5-gm. portions are weighed into a 600-c.c. beaker, about 250 c.c. of hot water added, and the beaker placed on the hot plate. When boiling, 30 c.c. of strong HCl is carefully added and the solution stirred until decomposition is complete. If pure acid has been used the sulphides which are not attacked can be filtered off, but it is safer to pass H_2S for a few minutes before filtering. The sulphides are washed back into the same beaker, cleaning the paper with bromine water, and dissolving in HNO_3 . The copper is then usually estimated by titration with cyanide or colorimetrically. A more accurate, though rather longer, method is to take to complete dryness, take up with HCl , and estimate the copper by the permanganate method.

The National Bureau of Standards

The work of the national Bureau of Standards is apparently only partly understood by the chemists of this country. Probably all are familiar with the fact that the Bureau of Standards prepares analyzed samples of various metallurgical products and calibrates thermometers and glass measuring apparatus. It is probably true, however, that the broader and perhaps more important work of the Bureau is little understood by the person who has not been brought in actual contact with its operations in various lines of industry. This broader field of work covers a line of operations in keeping with its name, and which will be of fundamental importance to scientists, particularly to the chemists and chemical engineers of this country. The ideal of this Bureau is to make it in practice what its name implies: a bureau of standards. This does not mean a bureau of standards for weights, measures, electrical units, and units of time alone, but while meaning this, also has a much broader meaning which is now being emphasized by the labors of the men in the department, and as an illustration of this, their work on paper may be cited.

The Government is a very large purchaser of paper of various kinds, weights, and qualities. It was a matter of fundamental importance to draw up specifications which would properly cover the purchase of grades of paper satisfactory for the various purposes desired. So little information was available along these lines that a small paper machine has been installed and experiments will be made to determine just what composition and method of treatment will be required to obtain a paper such as is desired for the various purposes. Such information will then be embodied in a specification drawn to cover the purchase of this material.

Work is also being done along other lines which are interesting to the chemical engineer, such as the development of standard methods for testing rubber and rubber goods; standard methods and standard apparatus for testing lubricating oils, particularly in the determination of their viscosities. Much work is also being done in comparing types of calorimeters, both for solid and liquid fuels. Suggestions will be ultimately made indicating types of calorimeters most suitable for various purposes. A large amount of work has already been done in the study of various pyrometers of all kinds. This work is being continued, and has done much toward evolving typical pyrometers which are satisfactory for all kinds of heat measurements.

The Bureau also has under consideration and in time will probably take up the definitions and specifications covering the composition of various industrial products, such as alloys. In fact, it seems to be the desire of the responsible heads of the Bureau to act in fact as well as in name as a bureau of standards, to which will be referred many industrial questions, which at present are only vaguely understood because the conception of them has been limited to that loosely formulated in trade practice or trade custom.—*The Chemical Engineer.*

Stripping Coal in Illinois

By J. W. IJAMS

*Stripping coal deposits has been done with teams on a small scale for several years. Five years ago stripping had started at Danville, Illinois, with an ordinary type of steam-shovel, loading dirt into a hopper from which it was carried by a belt-conveyor to the spoil bank. This was rather a crude method, but stripping coal at a depth of 25 ft. was done at a price that enabled the coal to be worked at a good profit.

Next a drag-line excavator was placed on the market. This operates successfully to a depth of 40 ft. or more, but will not handle hard shales such as are found in overlying coal deposits.

The early part of 1911, both the Browning Manufacturing Co. and the Marion Steam Shovel Co. brought out long boom, revolving, steam-shovels that deposit material 68 ft. from the centre of the machine and 48 ft. above the wheel base. With this machine it is possible to handle 4000 cu. yd. per day, working a double shift of 24 hr. per day. The Marion company has brought out 8 of these machines, which are now in operation. One of the first was placed at the mine of the Harrisburg-Franklin Coal Co. at Missionfield, Illinois. This is stripping coal lying at a depth of 18 to 27 ft., and is handling 1800 cu. yd. of stripping per day, working only 8 hr. per day, and is uncovering about 400 tons of coal per day. Three other machines of this type are working in the Kansas field and are doing about the same amount of work. A machine of this type will operate successfully in 35 ft. of stripping, although lately both the shovel companies have brought out a larger type of machine which is designed to operate in 45 ft. of stripping. The larger type of machine, however, is heavy, and naturally does not operate as fast as the smaller type. The stripping can be contracted on a price varying from 7¾ to 11c. per cu. yd. In an average case where the stripping lies at a depth of 25 to 30 ft. over a vein of coal 5 to 6 ft. thick, the amount of stripping to be removed for each ton of coal mined would be 4 yd., which at a price of 9c. would amount to 36c. per ton of coal.

The cost of mining coal by the stripping method, where the depth is approximately thirty feet, would be about as follows:

Stripping 4 yd. at 8½¢.....	\$0.34
Mining coal	0.25
Running over screens, general, and all other expenses. 0.10	
Total	\$0.69

The first cost of a plant as described above, including pumps, water connections, etc., amounts to about \$27,500. The depreciation on a shovel plant amounts to about 30% the first year and about 20% for each successive year. The cost of operating the plant is also comparatively high, as experienced shovel-men command a salary of \$150 to \$175 per month. However, ordinary labor can be used on the ground, making the cost of operating the shovel on a double shift about \$4000 per month. Taking into consideration the large depreciation and the large operating expense and general office and other overhead expenses, stripping can be contracted at a reasonable profit at a figure of 7¾ to 11c. per yard. The cost of operating shovels now in service fully substantiate this statement, as do also the figures on operating an ordinary type of steam-shovel, as there is little difference in the cost of operating a revolving shovel suitable for stripping coal-lands and the ordinary type of large steam-shovel such as is used every day in railroad and heavy construction work. Another argument in favor of stripping is that it does away entirely with the cost of sinking shafts, the cost of entry driving, of timbering roof, the cost of air supply and piping, and damages paid to injured miners, and from probable explosions. It also does away with delays

caused by strikes, as the mining is in an entirely open pit with ordinary labor.

The average cost of mining coal by sinking shafts and using ordinary methods is approximately 93c. per ton, showing a saving in favor of stripping of 24c., or nearly 40% saving in favor of the stripping method. Where the stripping is less than 30 ft., the price would be even lower, and where it went over 30 ft. it would increase somewhat. I think the maximum depth at which stripping can be operated successfully is about 35 ft. The only question arising is whether there are large areas of coal suitable to the stripping method, and whether they are close enough to railroads to be successfully operated.

Australasian Gold Output in 1911

A heavy decline in the amount of gold produced, both in Australia and in New Zealand, must again be recorded, according to the *Australian Mining Standard*. For several years past there has been a diminished production, and, although the shrinkage was reduced four years ago, the figures of later years show an increasing falling off, which is not pleasant reading. Not to go back beyond 1907, there was in that year a deficit of 323,329 fine oz.; in 1908 this was reduced to 112,548 fine oz.; in 1909, however, there was an increased deficit, the total being 115,507 fine oz., and this was followed by 266,819 fine oz. in 1910. Last year the Australasian deficiency was 270,713 fine oz., of a value of £1,149,915; the Commonwealth's share of the deficiency being 235,676 fine oz., the value of which would be well over a million sterling. The following table shows the authentic figures for each of the states, and for the Dominion of New Zealand, with the exception that, as the Tasmanian returns are not yet available, an estimate had to be made. At first sight it may appear that this estimate is unduly low; but it must be remembered that from before the end of September the Mt. Lyell company's mines and works were idle and remained so until the end of the year. Three months' supply of gold from the company's copper ore was therefore cut off, and when the actual gold yield of the island state is made available, it is believed that the estimate will not be far out. The total production for the past two years was as follows:

	1910. Fine oz.	1911. Fine oz.	Decrease. Fine oz.
New South Wales	189,214	181,121	8,093
Victoria	570,363	503,541	66,822
Queensland	438,784	381,845	56,939
West Australia	1,470,633	1,370,867	99,766
Tasmania	37,048	32,992	4,056
Total Commonwealth...	2,706,042	2,470,366	235,676
New Zealand	446,433	411,390	35,043
Total Australasia	3,152,475	2,881,756	270,713

The Chilean Nitrate Industry

The nitrate industry, according to A. A. Winslow, U. S. Consul at Valparaiso, enjoyed a prosperous year during 1911, the exports being about 2,000,000 Spanish quintals,* or 101,400 tons above that of the previous year, with an advance in prices of from 5 to 10%. Several new nitrate works were opened during the year and others enlarged. The outlook for the industry in 1912 is very bright, which means increased prosperity for the country in general. The nitrate company entitled El Loa, consisting of the nitrate establishments denominated María, Curie6, Angamos, and Anita, has acquired by purchase the Luisis and Candelaria nitrate properties, valued at £700,000. The Loa company will now be able to produce about 5,000,000 quintals of nitrate annually in addition to its yield of iodine. Steps have been taken in Antofagasta and Taltal to organize a joint-stock company, known as the Taltal Coöperative Nitrate Society, with a capital of \$2,000,000.

*Abstract from *Black Diamond*.

*1 quintal = 220.46 lb.

Russian Platinum Production in 1911

ST. PETERSBURG CORRESPONDENCE

The platinum business in the Urals during 1911, thanks to the high price of the metal, continued to develop and the production increased. The leading position is held by the Southern Verchotur district, including the platinum mines of the Nizhni-Tagil factories and the mines of the Platinum Company, Ltd. It is stated in a report just issued that the production in this district amounted to 230 poods,* 13 funts. 89 zolotniks, 47 dolyas. This marks an improvement, that is, compared with the production in the year 1910, of 19p. 18f. 26z. 62d.

In the neighboring Northern Verchotur district the quantity of platinum produced, although in itself important, is negligible compared with the large quantity accounted for by the Southern Verchotur district, namely, 21p. 23f. 27z. 6d., and, in contrast to the production of the southern district, the northern shows a decrease as compared with 1910, the decrease amounting to 37f. 25z. 38d. It is stated, however, that this insignificant decrease in the production is explained by purely temporary causes because of the reduction in the work consequent on the scarcity of labor in the mines of the Southern Zaozersk estate belonging to the Trans-Ural Mining Co., where the production was 2p. 8f. less as compared with 1910, which was 2p. 13f., while on the private mines on the Dyalinsk estate the production of platinum, on the other hand, showed a marked increase, amounting to 4p. 23f., or an increase of 1p. 10f. There is also to be added an increase in the production on the Nikolaieff Pavdinsk territories, the property of Vorobieff, which amounted to 14p. 9f. 78z. 79d., or a matter of 9f. 73d. more, as compared with the preceding year.

In the Perm mining district, which may be called the next in importance to the Southern Verchotur, the production of platinum amounted to 89p. 57z. 71d., or 1p. 21f. 54z. 89d. more than was won on that particular ground in the year 1910. In the Southern Ekaterinburg district there was a production of 1p. 38f. 95z. 43d., which marked an increase of 5f. 1z. 86d. on the preceding year's production. It may be observed that at this particular spot the production of platinum is carried on exclusively in the mines of the Systersk factories. In the Northern Ekaterinburg district the production of platinum is not important, being only 13z. 39d. Thus we have for the year 1911 a platinum production in the Urals of:

Districts.	p.	f.	z.	d.	p.	f.	z.	d.
Southern Verchotur...	230	13	89	47 + 19	18	26	62	
Northern Verchotur...	21	23	27	6 — ..	37	25	38	
Perm	89	..	57	71 + 1	21	54	89	
Southern Ekaterinburg.	1	38	95	43 + ..	5	1	86	
Northern Ekaterinburg. .	..	13	39	+	23	
Teherdinsk.....	—	—	—	—	—	—	—	—
Returns not yet known.								
Total for the Urals.	342	36	91	14 —

The following table shows production since and including 1902:

	Poods.	Funts.
1902	374	23
1903	366	35
1904	306	9
1905	319	32
1906	352	29
1907	328	33
1908	298	4
1909	312	21
1910	334	23
1911 (exclusive of Teherdinsk).....	342	36
Total for 10 years.....	3,337	5

*1 pood = 40 funts = 526.64 oz.
1 funt = 96 zolotniks = 13.16 oz.
1 zolotnik = 96 doll = 0.137 oz.
1 dolya = 0.0014 oz. = 3c. in pure gold.

Copper Producers' Association Report

The report of the Copper Producers' Association for February shows a decrease of 3,340,645 lb. in stocks on hand. This reduces supplies this year by more than 26,514,000 lb. and establishes a record for the smallest surplus in the history of the Association. Production for February was 116,035,809 lb., compared with 119,337,753 in January. Domestic deliveries fell off by 6,115,534 lb. and exports by over 17,000,000, making a loss in total deliveries of 23,135,341 lb. The following table shows the conditions of the supply and production of copper as compared with January:

	Pounds.
Production, February	116,035,809
" January.....	119,337,753
Decrease	3,301,944
Domestic deliveries, February.....	56,228,367
" January.....	62,343,901
Decrease	6,115,534
Foreign deliveries, February.....	63,148,096
" January.....	80,167,904
Decrease	17,019,808
Total deliveries, February.....	119,376,463
" January.....	142,511,805
Decrease	23,135,342

Transvaal 1911 Gold Output

The Chamber of Mines statistics for 1911 show that the gold production of the Transvaal for that period amounted to 8,237,723 fine ounces, valued at £34,991,620, of which the Rand was responsible for £33,543,479 and the outside districts £1,448,141 of the total value. This is a record production to date, the yield during 1910 (also a record) being 7,280,542 fine ounces, valued at £32,001,735. The Transvaal dividends for 1911 were:

Gold:	
Rand	£7,719,610
Outside districts	303,351
	£ 8,022,961
Diamonds	300,000
Coal	250,000
Tin	163,250
	£ 8,736,813
Financial, industrial, and land.....	2,397,650
Total	£11,134,463

AN agreement has been signed by the Amalgamated Zinc (De Bavay's), Ltd., and the Potter's Sulphide Ore Treatment Co., under which the option of the former over the patent rights of the Potter's company has been extended for a period of six months. The conditions are: (1) A cash payment of £5000, which is to be regarded as part payment of the purchase money if the option be exercised, or forfeited to the Potter's company if the option be not exercised; (2) if the option be exercised, the balance of the purchase money, namely, £30,000, to carry 5% so long as it remains unpaid; (3) the hearing of all pending law proceedings to be stayed during the option period. It is generally considered likely that this extension, particularly in view of the condition last mentioned, may perhaps indicate an early abandonment of the voluminous and complicated litigation now pending between various owners of flotation process patents. This is the second extension of its option which the De Bavay company has obtained, at a cost of £11,000, so that apparently the directors mean business, though it must be stated that in the event of the option being exercised £10,000 of this amount will form part of the purchase money.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

How Can Alaska Be Developed?

The Editor:

Sir—The letter from Julius Thompson, and the comment thereon by H. Foster Bain, both appearing in your issue of February 17, have aroused a desire on my part to add some remarks to the discussion of the contemplated change of the national mining laws from the viewpoint of a prospector.

Mr. Thompson contends that, in order to promote the further development of Alaska, the prospector must be given the utmost facilities for acquiring mineral lands, and that if he cannot obtain title to these, and if he should be forced to lease from the Government, he will cease to prospect and mine in Alaska. I do not agree with him in any of these contentions. I have some personal knowledge of the special conditions retarding operations in that country, gained during a six years' residence there, beginning in the days preceding the Klondike boom, when all the disadvantages of that remote region existed to a considerably greater extent than at the present time. 'Miner's Law' ruled the land then, and it may be safely assumed that regulations adopted by a small body of men for their own government express with tolerable accuracy the dominant ideas and wants of the individuals. They invariably limited individual holdings by cutting down the size of claims, by allowing only one claim in a district to each person (except the discoverer of new deposits, who could hold two claims), by not tolerating locations by proxy, and in a number of other ways. If prospectors who have everything so entirely their own way as these Alaskan pioneers had it, do not become land-grabbers, it would appear extremely unlikely that they would at any time make much of an outcry for more land. Whoever knows the real prospector in his haunts knows also that he is usually too busy trying to develop his discovery to bother about adjoining land, and that he always welcomes neighbors who will get in and dig and by their additional finds enhance the value of his own. If he could eliminate those other 'prospectors' who will surround his discovery locations and, without making the slightest effort to contribute to the development of the country, await an unearned increment accruing from the prospector's labors, he would be quite content with a minimum acreage, so long as it included his orebody.

Leasing was in vogue on every creek along the Yukon that had enough 'pay' to justify it, and it is astonishing to learn from Mr. Thompson that 90% of the present population of Alaska condemn the practice as un-American. The natural inference is that now only 10% of the residents of Alaska are prospectors and miners, as these take kindly to leasing wherever they go, and, providing the terms are otherwise favorable, it is hardly conceivable that they would develop a prejudice against leasing from the Government. Of course, laws which a great majority of an American community do not want should not be forced on them, but on the other hand, a general objection to the passage of new laws should not be assumed merely on the ground of a few assertions which are emphatically contradicted by the past actions of the persons about whom they are made. In my opinion, the statement is also quite unwarranted that nothing but title to the land will satisfy the prospector. He very rarely obtains a United States patent, and the possessory title under which he usually holds his claim does not give such absolute security of tenure that it could not easily be improved upon under a leasing system.

It appears to be generally conceded that the development

of the country's resources must be encouraged by all means, and although the present conservation movement seems to be a step in the opposite direction, its sole aim undoubtedly is the prevention of wasteful exploitation. The enforcement of such a policy does not preclude a simultaneous encouragement of diligent search for new deposits. It should be quite practicable to so frame the proposed new enactments that they would offer as great inducements to the prospector as do the present laws, and to reward in an adequate manner the discoverer of mineral resources which add to the present or the future wealth of the Nation, and to abolish at the same time existing abuses. The principle of discovery, upon which our present mining code is based, seems to be sound and should be retained, although it has in the past been honored in the breach rather than in the observance. The trouble was probably caused largely by the difficulty of arriving at a satisfactory definition of what constituted a discovery, and instead of attempting a solution of this problem, a number of makeshifts have been provided to regulate the evasion of the first requisite of a legal entry. The next principle involved, that of use, or occupancy, has been nominally adhered to by requiring a certain minimum performance of labor. In practice this has been quite futile in its effect, and has never prevented the holding of mineral ground for purely speculative purposes. The advance of scientific and practical knowledge since the enactment of the present mining laws should make it possible to define the word 'discovery' in such positive terms as would leave little or no doubt of its construction. Then it should be possible to provide liberally for the recognition of the discoverer's service, perhaps by giving him an equity in future royalties and, of course, a preferred right to a mining lease, but it seems to me that, under a leasing system, rights acquired through a duly verified discovery should not be made contingent upon use or occupancy. The idea is obsolete and does not fit well with modern mining conditions. Its present enforcement results largely in a waste of time and labor and tends to retard rather than to advance development, especially in the case of those types of deposits which are not immediately productive but which are of great potential value, as judged by geological evidence.

I can see no reason why the proposed change to a leasing system should be condemned in advance, although I realize also that the new laws might be made extremely distasteful to the prospector.

ANTHONY ELFFNER.

Diamonds in China

The Editor:

Sir—In your issue of November 25, 1911, under 'Concentrates' you have, "Black diamonds are harder than white ones, their color varies from dark gray and brownish opaque to black. They are found only in Brazil." I would like to add that black diamonds, weighing two or three carats, are also found in two provinces in North China. They are superior in hardness to ordinary diamonds, have a fairly good brilliancy, and are used as ornaments by the natives. They are picked up in the rice and *kaoliang* fields shortly after the rainy season. It is curious that the diamonds are never found in the same fields two years in succession. I think that some years ago the Germans had permission or a concession to search for diamonds in the Province of Shantung. This, however, proved unsuccessful, as the coolies kept all the diamonds they found, so that the concession was allowed to lapse.

EDWARD DI VILLA.

Tientsin, China, January 4.

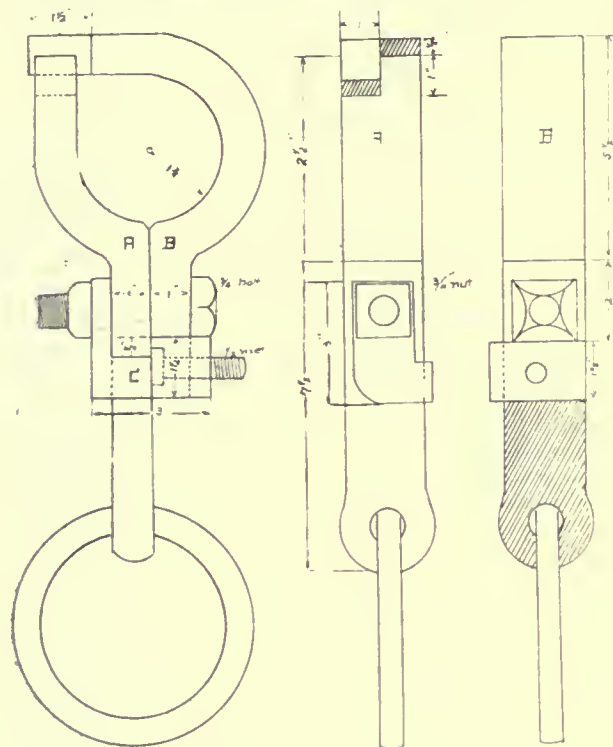

[The story among the natives in regard to these diamonds is that they become lodged in the meshes of the straw sandals used by the farmers while working in the fields, and are thus recovered. There seems to be no reliable estimate of the number found annually, but it is certainly small. Mr. di Villa is apparently the first to call attention to the fact of these diamonds being of the black variety.—EDITOR.]

Clamps for Stamp-Milling

The Editor:

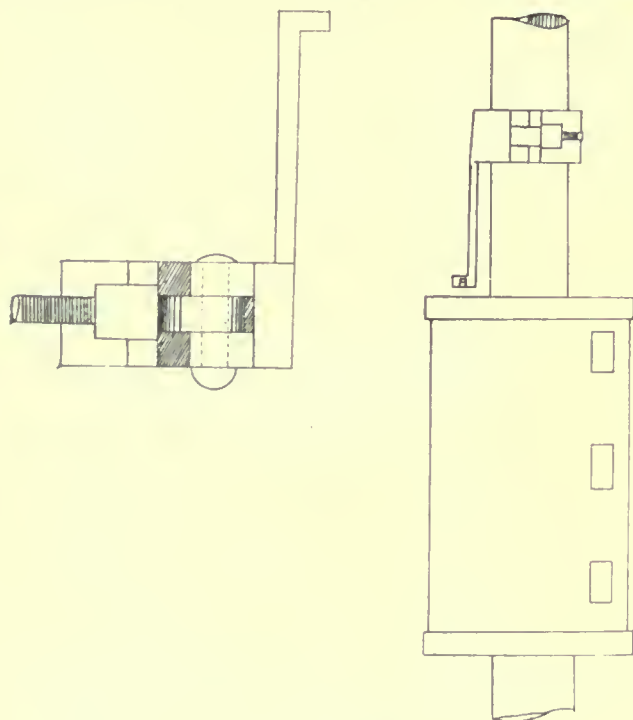

Sir—I enclose drawings of two devices used at the Lightner mill, Angels Camp, which may be of interest to readers of the *Mining and Scientific Press*.

The first one is a clamp used for raising stems. In the

STEM CLAMP.

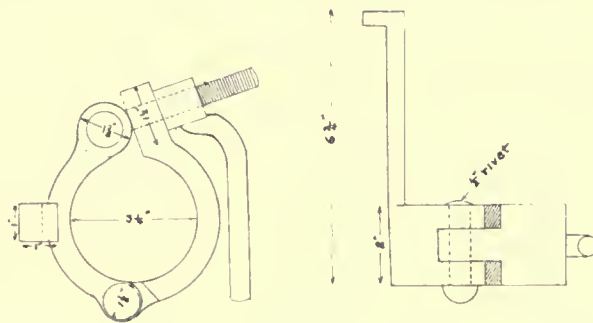

turning of stems end for end, after being broken in the boss, the broken end is often so battered that the ordinary ring type of clamp will not go over the battered top. This difficulty is obviated by use of the clamp shown in drawing.

TAPPET GAUGE.

as it can be quickly and securely placed around the stem below the battered end. The clamp fits firmly and will not slip when stem is twisted.

The second shows the tappet gauge employed at this mill for resetting tappets upon the stamp stems. The wearing of shoes and dies of a stamp battery necessitates the constant re-setting of tappets in order to maintain a uniform drop. The tappet gauge shown not only renders easier the setting of tappets but shortens the time usually spent in this operation. With this clamp the stem cannot drop below

TAPPET GAUGE.

the set distance, consequently the use of a chain block is never required. In operation the clamp is placed around the stem the distance above the tappet which the stamp is required to be dropped. The keys are then loosened and the stem allowed to drop until projection A rests on the tappet. The keys are then set, the clamp loosened, and the gauge removed, when all is ready to start again.

Iron as a Cyanicide

The Editor:

Sir—There is nothing new in the statement that small fragments of iron in the ore will consume cyanide during lixiviation. However, a word regarding such a common cyanicide may not be amiss. Julian and Smart make the statement that iron dissolves in KCN, yielding potassium ferrocyanide; one part of iron consuming 7 parts of KCN, the reaction also consuming oxygen, which is required for the dissolution of the precious metals. In a recent cyanide test this cyanide occurred in such a way that it made its presence known. The table concentrate from an ore carrying a small amount of sulphide, after standing a few hours, showed rusty streaks which gave the concentrate the appearance of an oxide rather than a sulphide.

One gram of this rusty material was withdrawn by means of a magnet and treated 16 hours in a cyanide solution, with a resulting consumption of 34 lb. KCN per ton of material. Investigation before cyanidation showed that only about 10% of this rusty material was metallic iron; the rest was simply discolored gangue clinging to the iron. The rust gave this pulp the appearance of containing limonite and, as nearly as could be determined by intensity of discoloration, none of the rust was dissolved. A consumption of 34 lb. KCN per ton of solids treated is 1.7% of 1000 mg. or 17 mg. KCN.

Since the entire consumption is chargeable to metallic iron, which amounted to 100 mg., and iron consumes cyanide at the rate of 1 to 7, it can be seen that no appreciable amount of iron was dissolved, though the cyanide consumption due to its presence sounds large. Since this magnetic material constituted only about 1% of the concentrate, it is evident that the cyanide consumption due to iron in the concentrate would have been 0.31 lb. Going one step farther, it is seen that the consumption in the ore would have been negligible in a laboratory test.

One thing worthy of note is that, as shown by the calculations, after iron consumed cyanide at the rate of 34 lb. per ton it had only begun, and that in long-period agitation (6-day, for instance) it is important to select crushing machinery that will contribute a minimum amount of metallies.

WILL H. COGHILL.

Evansville, Illinois, March 1.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

VOLUME of the lithosphere, or stony crust of the earth, including the continents elevated above the sea, is estimated at 1,633,000,000 cubic miles.

VELOCITY of an air current that appears almost stagnant may be estimated, where an anemometer is unavailable for immediate use, by the use of a heavy rag, or a piece of brattice cloth charged with dust. A rap of the hand on the rag or cloth will raise a cloud of dust which the air current will carry away, allowing the observer to form an estimate of the velocity.

WOOL GREASE, from wool cleaning, is sold to refiners, who by means of distillation obtain stearin (the better qualities of which are used for soap and the remainder for leather dressing) and olein, or wool oil, which is blended with other oil and used in the shoddy manufacturing districts. The residuum of wool grease distillation is known as wool pitch and is used, among other things, for insulating electric wires.

TOTAL sulphur in coal may be determined in the following manner. One gram of the substance is intimately mixed in a porcelain crucible with 2 gm. copper oxide and 1 gm. anhydrous sodium carbonate. The crucible is placed in a hole in an asbestos pad and heated with a bunsen burner; if stirred occasionally, the action is complete in about two hours. When cool the crucible is transferred to a large beaker and moistened with bromine water to oxidize any sulphites to sulphates; the residue is then treated with hydrochloric acid and bromine water, heated to effect solution and finally to expel bromine, filtered, and the sulphur estimated in the filtrate in the usual way.

CAUSE for the unstable condition of the graphite industry in this country is found in the facts that the largest domestic deposits are schists which carry small flakes of graphite disseminated through them and that the separation of the graphite from the accompanying minerals, especially mica, in such rocks is a problem of unusual difficulty. The one firm which can be said to have become firmly established in the treatment of such graphitic rocks, the Joseph Dixon Crucible Co., possesses an important advantage over other firms in that it manufactures much of its product into graphite paints, graphite grease, etc., before placing it upon the market. When the margin of profit is small, such control of markets becomes of vital importance.

AUTHORITY controlling the use of explosives in the United States lies with the legislatures of the states. Up to the present day the regulations in different states have been far from uniform and in many states have been inadequate. Accurate information in regard to the action of different kinds of explosive materials is necessary for efficient legislation, and such information has been nowhere available. It is to remedy this condition and provide accurate data in regard to explosives, that tests of coal-mining explosives are being made by the Bureau of Mines. These tests serve to show which explosives are safe and which are dangerous for use in coal-mining, and to determine such other properties of explosives as are of importance in the safe and efficient use of these materials.

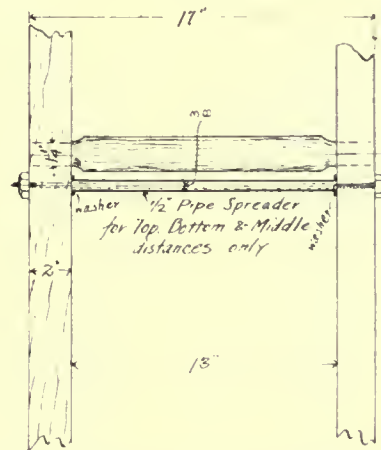

LOSS of head or pressure in compressed-air transmission has been found to be proportional directly to the density and the length of pipe, as the square of the volume discharged and inversely as the diameter in inches. In other words, the economy of transmission depends, exactly as in the transmission of direct-current electricity, on how much

capital is to be tied up in the first cost. For example, in driving the Jeddo adit a 6-in. main was used to convey the air power to two 3¼-in. machine drills over a distance of 10,900 ft., and the loss of pressure was only 0.002 lb., a practically negligible loss. However, it would not be economy usually to design a pipe for such low velocity of air, as the interest and depreciation on the additional investment over the cost of a smaller pipe-line would more than counterbalance the saving in fuel, unless a future demand should make a decided change in the conditions.

WATER legislation, according to the 'California system', recognizes the law of appropriation and riparian rights, working side by side. The states which have adopted this are California, Montana, North Dakota, South Dakota, and Washington. Oregon recognizes riparian rights obtained prior to 1909, but at present only appropriated rights can be initiated. In these states having the 'California system', appropriation may be made subject to prior appropriation and riparian rights. As the United States is the owner of the public land and primarily of the water upon its land, and chooses to allow appropriations of water upon its land, the patentee of public land acquires the riparian rights that go with it (where they are recognized) subject to all prior appropriations, but no future appropriations disadvantageous to his riparian rights can be made over his protest, though the surplus may be appropriated.

TIN SCRAP is utilized by detinning old tin cans at the plant of the London Electrical Works Co., Ltd., which treats 20,000 tons per year. The process consists in unloading the cans upon a shaking conveyor, which frees them from readily detachable dirt. This is also used as a picking belt, only tinned scrap being allowed to enter the works. The cans then go through a series of drums, in which they are crushed, perforated, and heated. In the last, all extraneous matter, including solder, is removed. The cans are then pressed into briquettes ready for the detinning process. So far, in the United States, conditions of distance and wages have operated to render detinning of old cans more or less unprofitable, unless the new dry chlorine process has furnished what has long been hoped for; namely, a process so good as to overcome these inherent disadvantages and lead to a new industry which can still support highly paid labor.

MINE LADDERS should be constructed of good timber, as it is not worth while to risk a fall by a miner by using cheaper material. A convenient and good way to construct a ladder is shown in the illustration. The ends of the ladder rounds are tapered and fitted into round holes.

The ladder is held together by the 3/8-in. rod, which is provided with nuts on both ends, and the 1/2-in. pipe slipped over the rod serves as a distance-piece. Washers at each end prevent the pipe sinking into the wood. This is a more satisfactory method than splitting the ends of the rounds and wedging them into the sidepieces. Broken rounds can thus easily be replaced without resorting to the usual practice of nailing a piece on.

Special Correspondence

TORONTO, CANADA

TORONTO MEETING OF THE CANADIAN MINING INSTITUTE.— PAPERS AND DISCUSSIONS.

The fourteenth annual convention of the Canadian Mining Institute held at the King Edward hotel, Toronto, March 6 to 8, was the most important meeting since the establishment of the Institute. The attendance, which was nearly 300, was thoroughly representative of the mining interests of Canada, and included many prominent Americans. The papers read were of unusual interest and gave rise to several animated and instructive discussions. The chair was occupied by the president, Frank D. Adams, of McGill University. The convention was opened by an address of welcome by W. H. Hearst, Minister of Lands, Forests, and Mines for Ontario, who spoke of the growth of the mineral industries of the province. These have trebled in value in the course of five years and the silver mines of Ontario now produce one-seventh of the world's total production. Mr. Hearst paid a high tribute to the work of the Institute and pointed out that the field for mineral exploitation had been extended by the recent acquisition by the province of additional territory to the extent of about 100,000,000 acres, concerning the resources of which very little is known.

H. Mortimer Lamb, the secretary of the Institute, read a message from the Duke of Connaught expressing his regret at his inability to be present, and conveying his best wishes.

Frank D. Adams delivered the annual presidential address. He congratulated the members on the continued prosperity of the mining industry. The small decrease shown in the total mineral output of Canada was directly due to the protracted strike of coal miners in the West, which, besides lessening the coal output, had materially affected the copper smelting industry of British Columbia. He reviewed the work of the Institute, which now has 945 members on the list, as compared with 850 last year, and spoke of the service rendered by the geologist to practical mining, giving numerous instances of scientific discoveries which have proved of great value to the industry. The increasing appreciation of the value of geologic work is shown by the fact that so many of the large mining and railroad companies have secured the services of geologists on their staffs.

John McLeish, of the Canadian Department of Mines, presented the preliminary report of the mineral production of Canada for 1911. The figures, which are given subject to revision, show a total metallic output of the value of \$46,197,428, and non-metallic \$56,094,258, making a total of \$102,291,686, as compared with \$106,823,623 for 1910. The only item of metallic production showing an increase was pig iron, which was produced to the amount of 917,535 tons, valued at \$12,306,860, as compared with 860,797 tons, valued at \$11,245,622, in 1910. The coal output was 11,291,553 tons, valued at \$26,378,477, as against 12,909,779 tons of the value of \$30,909,779 the previous year. Statistics of smelter production showed 2,192,727 tons of ore treated, as compared with 2,683,714 tons in 1910. The miners' strike and the closing down of the Granby smelter are assigned as causes of the shortage.

T. W. Gibson, Deputy Minister of Mines for Ontario, presented a preliminary report of the mineral production of Ontario for 1911 showing a total value of \$41,432,898, as compared with \$39,313,895, or an increase of 5.38%. E. Jacobs presented a preliminary review and estimate of the mineral production of British Columbia for 1911, compiled by W. Fleet Robertson, Provincial Geologist, showing a total value of \$23,211,816, or a decrease of \$3,165,250. Theodore Denis, Superintendent of Mines for Quebec, presented the preliminary report of mineral statistics for that province for 1911, giving the total value of the output at \$8,567,143, as compared with \$7,323,281 for 1910.

At the afternoon session several papers on coal mining were read. Charles H. Clapp discussed the geology of the Nanaimo coal district, which furnishes one-third of the

British Columbia output, pointing out that there are frequently great variations in the seams, due to the inequalities of the roof and the floor, which are often slickensided or contorted. These irregularities and disturbances are frequently the cause of industrial disputes on account of the difficulty of fairly adjusting wages where they occur. D. D. Cairnes dealt with coal formations of the Yukon, where lignite is found in the Tertiary formation and coal in qualities ranging from lignite to anthracite occurs in the Jura-Cretaceous. The most important deposits are those of the Tantalus area. The known Tertiary bed covers 2090 square miles, while the Jura-Cretaceous formation is 4000 square miles in area. The estimated amount of coal in known coal areas is 3,325,290,000 tons.

H. Foster Bain contributed a paper on 'Fuel Problems of the Pacific,' which was read by James McIlwain. The coal situation on the Pacific is rapidly changing, by reason of the competition of the cheap coal of Japan, which in some cases is delivered for less than \$1 per ton, and the use of fuel oil, which is burned by many steamships. The output of Japanese coal has risen from 500,000 tons in 1877 to 15,000,000 tons in 1910. Hydro-electric power is also largely taking the place of coal for manufacturing purposes. 'International Coal Competition' was the subject of a paper by Allan Greenwell, which was read by the secretary. He pointed out that in working power a ton of coal equals the labor of 672 men for ten hours, and that it would require the labor of half the able population of the world to man the present steam-driven navigation. Canada is the only coal-producing country which consumes more of the imported than the domestic article. E. Jacobs gave statistics showing that 97% of Canada's usable coal deposits are in the Western provinces.

In the course of the discussion which ensued, J. B. Porter replied to Mr. Greenwell's statement as to the undue consumption of imported coal, pointing out that this is due to the demand for anthracite. The condition is only temporary, and the export trade will grow rapidly. Robert V. Norris regards the competition of oil for fuel as a serious matter. On the Pacific coast the only demand for coal is for domestic purposes, which renders useless the slack, amounting to about 40%. The market for coal is limited by its transportation range, and therefore it is natural that Eastern Canada should import American coal and the American West look across the border for a supply. This opinion was endorsed by several other speakers, who favored the free exchange of coal across the border. E. W. Parker said that the use of approximately 52,000,000 bbl. of oil for fuel displaced 15,000,000 tons of coal. Some of the Japanese steamers use oil on their trips west and cheap Japanese coal on the return voyage.

A paper by Victor G. Hills on the tungsten deposits of Nova Scotia dealt with the occurrence of scheelite in gold-bearing rocks. Other speakers said that this mineral had also been found in Poreupine and the Manitou area, and was likely to occur in most gold districts.

In the evening an interesting address on accident prevention was given by W. H. Tolman and illustrated by colored slides showing various safety devices in use by railways and in the steel industry. He complimented the American iron and steel interests in accomplishing as much in the way of prevention of accidents in three years as the Germans have done in twenty-five years. After discussion a resolution was adopted to the effect that the question should be brought to the attention of the Government.

Sanitary conditions in mining camps was the subject of an address by Charles H. Havi, in which he advocated timely action by health officials in the early days of a district, instead of waiting until a town had grown up before anything was done.

E. W. Parker gave a comprehensive address on the coal-fields of the United States, expressing the opinion that with the adoption of improved methods production would continue for two centuries.

On the second day most of the morning was occupied by a discussion on the proposed workmen's compensation act, opened by an address by Charles A. O'Connell, of Cobalt,

who presented at some length the views of the Cobalt mine owners. They are prepared to concede the principle of the English act that a workman injured by accident is entitled to compensation, even though there had been no negligence on the part of the employer or defect in the plant, and favor a system under which the employer and employed should contribute. The compensation to dependents in case of death should be equal to three years' earnings, but not less than \$1000 or more than \$2500. After discussion a committee was appointed to draft a resolution to be submitted at a later session.

Robert H. Richards discussed the concentration of silver ores and presented a series of tables showing the results of tests made on the concentration of Cobalt ores. J. W. Evans gave a description of the Evans-Stansfield electric furnace, by which he claims it has been found possible to produce tool steel direct from titaniferous magnetite at a cost of 2.01c. per pound of steel.

F. A. Jordon gave an address on the concentration of iron ores at Moose Mountain, Ontario, explaining the difficulties encountered in treating a refractory ore. These were not overcome until the company adopted magnetic separation and installed a Gröndal plant of 800 tons capacity, which is expected to be in steady operation in May. David H. Browne described recent improvements and additions at the Canadian Copper Co.'s works at Copper Cliff, Ontario, where the ten stands of acid converters have been removed and five basic converters substituted. The erection of two large reverberatory furnaces was begun last year, and the first one was blown in last December.

The feature of the afternoon session was the reading of a paper by T. A. Rickard on 'The Domes of Nova Scotia,' illustrated by a number of lantern slides explaining clearly the geological characteristics of the gold-bearing rocks. At its close, John Hardman asked if Mr. Rickard had not made a report to the Government of Nova Scotia in 1905, and why that report had not been published. Mr. Rickard stated that he had made a report to the Nova Scotia Government on the gold deposits, the substance of which was that while the deposits are not of such a character as to justify the organization of companies with heavy capitalization to operate them on an extensive scale, they do justify the Government in encouraging mining enterprises by simpler and less costly methods.

A. E. Barlow read a paper on the origin of the quartz veins of the Porcupine district, followed by one from Reginald E. Hore on the origin of the Porcupine gold deposits. Mr. Barlow expressed the opinion that there is less free gold in depth and the ore becomes more refractory. This drew forth a strong protest from H. T. E. Haultain against the assumptions of geologists. He said that a man brought up as a geologist remained hopelessly benighted, and that he was pleased to see that the conclusions of alleged eminent scientific experts were not always in accordance with each other.

Charles A. O'Connell dealt interestingly with Cobalt, its past, present, and future, and J. B. Tyrrell gave an address on the copper mine country in the extreme north of Canada, giving an account of early discoveries and present conditions. In the evening the members enjoyed a smoking concert.

On the third day J. Parke Channing gave an interesting address on the Miami copper mine and mill. A paper by F. L. Garrison on 'The Decrease of Value of Ore-Shoots with Depth,' drawing adverse conclusions, was replied to by J. F. Kemp, who said sufficient allowance was not made for the importance of secondary enrichment. T. A. Rickard favored Mr. Garrison's conclusions. Carl Reinhardt presented a paper on the origin of the ores of Cobalt, which also provoked some controversy. He attributed the origin of the ores to the Keewatin lavas underlying the diabase and overlying the Keewatin cherts. After a brief discussion, a resolution as regards the proposed workmen's compensation act was unanimously adopted. The election of president resulted in favor of A. E. Barlow, of Montreal. The other officers were chosen previously to the convention. The convention closed with the annual banquet at the King

Edward hotel, at which the principal speakers were G. G. S. Lindsey, W. R. Brock, A. M. Hay, J. Parke Channing, Frank D. Adams, H. A. Machin, W. G. Miller, C. A. O'Connell, and H. Mortimer Lamb.

JOHANNESBURG, TRANSVAAL

RESULTS FOR 1911.—SIGNIFICANT CHANGES.—GRADE VERSUS WORKING COST.—CONSOLIDATIONS AND COST INCREASES.—NEED FOR REDUCTION.

With the appearance of the analysis of mining results for December, issued by the Chamber of Mines, it is possible to summarize those of 1911 and make comparisons with preceding years. It may not be necessary to go back for purposes of comparison beyond 1909, because prior to that date conditions were somewhat different from those prevailing today, in several details, but in comparing present-day results with those of two years ago, some significant changes are noticeable, as the following figures show:

Year.	Tons Milled.	Average			
		Yield, per ton.	Cost, per ton.	Profit, per ton.	Total Profits.
1909...	20,543,750	28s. 11d.	17s. 1d.	11s. 6d.	£11,794,376
1910...	21,432,541	28s. 6d.	17s. 7d.	10s. 6d.	11,216,105
1911...	23,888,258	27s. 11d.	18s. 0d.	9s. 7d.	11,415,861

The most striking feature, perhaps, of the above statement is the steady decline in the yield per ton milled and the almost equal steady increase in the cost of production per ton, with the natural result that profits per ton are donbly affected. It need scarcely be pointed out that after the recent extensive preaching of the doctrine that mines should be worked so as to procure the largest legitimate profit, the above results are anything but satisfactory, as it is known that in several instances this doctrine has been followed. Disappointing, however, as these results are, they are not so bad as promised during the first half of the year, when the yield sunk to 27s. 6d. per ton milled. A recovery of 27s. 11d. for the year shows that the grade of ore milled has taken at last an upward turn. This change for the better in the yield is not altogether due to selective mining, as several mines of decidedly higher grade were started during the second half of the year and could not fail to produce a beneficial effect on the grade, which in August had sunk to as low as 26s. 8d., but in December had recovered to 27s. 10d. per ton. It has always been the case on the Rand that an artificial raising of the grade of ore sent to the mill has been attended with higher working costs, which have to some extent neutralized the benefits, and it is therefore all the more encouraging to find a natural rather than an artificial increase in grade taking place. There are, however, no prospects of a natural increase in grade being sustained on the Rand to any extent, for even during the last three months of the year, when the grade of ore milled steadily increased, exactly one-half of the increase was swallowed up by the increased working costs. In the present condition of affairs the experience of the past three years goes to show that with an honest or natural yield, low working-costs per ton are more conducive to profits than artificial attempts made to improve the yield.

In dealing with the costs, it may be interesting to refer to the statement of results for the year 1909, in which it is shown that with working costs at 17s. 1d. per ton milled (the lowest cost yet reached on the Rand), the profits constituted a record at £11,794,376, and with the present higher costs it will require an increased tonnage milled of five millions to yield the same total profit. It may seem impossible to raise the present-day grade by mining on existing lines, to that of 1909, but there ought to be less difficulty experienced in bringing the costs of working down to, if not lower than, those of three years ago. This was one of the objects aimed at when the extensive amalgamations were brought about, but in almost every instance these amalgamations seem to have added to rather than reduced the costs of working. This increased cost of

working seems to have been brought about at the different amalgamated concerns by different causes; at the East Rand Proprietary Mines, by inefficient administration and by placing the individual mines under less qualified control than before; in others, by more expensive administration and extra costs caused and rendered unavoidable by reason of the amalgamation. So far, nowhere does amalgamation seem to have resulted in improved methods of working to such an extent as to bring down the working costs; not because the methods cannot be improved, but because those in control do not seem to have the necessary courage to bring about the necessary innovations. There is more than one instance where the costs of working were expected to be in the neighborhood of 12s. per ton, but continue about 19s. per ton, with but little prospect of being reduced for several months to come. Results for 1909 may be taken to show that working costs can be reduced, and there must be something wrong where an increased output of more than 3,000,000 tons results in adding a shilling per ton to the cost of working. It is a well known axiom in mining that a big or growing output should cover a multitude of sins, particularly with regard to working costs per ton, and why it should not be the same on the Rand is difficult to explain.

LONDON

REPORT OF THE EXPLORATION COMPANY.—ENCOURAGING OUTLOOK.—THE BUENA TIERRA MINE.—PLANS FOR DEVELOPMENT.—RECORD OF THE MT. MORGAN.

The Exploration Company, of which R. T. Bayliss is the leading spirit, had not much of startling novelty to report as regards its doings during the past year. The only item of conspicuous interest is the flotation, as a separate company, of the Buena Tierra silver-lead mine. But before referring to this venture, I will give an outline of the position of the Exploration Company. The profits for 1911 were £34,871, and a dividend of £37,500, or 5%, was distributed. This is the same rate as last year. Mr. Bayliss, in his speech to the shareholders, stated that little change had been made in the company's holdings, and that the El Oro and Tomboy continued to be the principal producers under their control. He reported that the new subsidiary, the Santa Rosa, in Zacatecas, was now equipped with a modern 100-ton plant, and that development work at the Buena Tierra, in Chihuahua, had proceeded so satisfactorily that the time had arrived when it was advisable to float a separate company to continue operations. The Exploration Company still holds large blocks of shares in American copper companies, acquired before the last collapse of the copper market, and Mr. Bayliss expressed his confidence that within a short time these securities would advance in value owing to the present position as regards production and consumption of the metal. He also reported that the company's real estate in Johannesburg, which has for so long been unmarketable, is at present forming the subject of hopeful negotiations. Another point of interest is that a new company, the China Clay Exploration Syndicate, has been formed for the purpose of acquiring china-clay pits in Cornwall, and of applying the new refining process purchased two years ago. On the board of the syndicate, besides Mr. Bayliss and Mr. Shaw, are James Wickett and J. W. H. Bolitho, two well known Cornishmen.

As recorded in the preceding paragraph, the Exploration Company has floated a subsidiary, the Buena Tierra Mining Co., for the purpose of acquiring the mine of that name in the Santa Eulalia district, Chihuahua, Mexico. The mine has for some time been a producer, under local ownership, of argentiferous lead carbonate, occurring in limestone, and is on the same group of lodes as the Potosí, Santo Domingo, Velardeña, and Mina Vieja, mines which have been profitable producers. The ore also contains a large proportion

of iron. During the 18 months that the mine has been worked by the Exploration Company, 47,624 tons of ore was shipped to the A. S. & R. smelter at Chihuahua, and the price received was \$7.71 per ton. The cost per ton of ore delivered at the smelter was \$3.89, leaving a working profit of \$3.82. The results would have been more favorable if it had not been for irregularity in the operations of the smelter. The average content of recent shipments was 11 oz. silver and 16% lead. It is expected that the sulphide zone will be reached at 150 or 200 ft. below the seventh or present bottom level. Complete statements of the position are given by R. T. Bayliss, R. M. Raymond, and A. C. Brinker. They estimate the reserve at 250,000 tons, averaging \$7.50 per ton, giving a profit of \$4.50 per ton, and the monthly output will be about 4000 tons. The yearly profit is therefore figured at £43,000 for 5 years, the life of the present reserve. The capital of the company is £330,000. Of this, £300,000 in cash or shares is the purchase price paid to the Exploration Company, which had devoted £167,927 to the purchase, development, and equipment of the mine. In the present issue, it is intended to devote £30,000 cash as working capital.

The interim report of the Mount Morgan Gold Mining Co., Rockhampton, Queensland, is causing some perturbation in this country, and the facts disclosed come as somewhat of a surprise. During the half-year ended November 30, 82,476 tons of auriferous copper ore was smelted, together with 43,131 tons of fluxing ore from the Many Peaks mine; the former yielded 2269 tons copper and 36,136 oz. gold, and the latter 1009 tons copper and 335 oz. gold. In addition, 53,570 tons of silicious sulphide ore was treated by the chlorination process and yielded 26,726 oz. gold and 420 tons copper. The content of Mt. Morgan ore smelted during the half-year has shown a considerable decrease as

TOMBOY MINE, COLORADO.

compared with the figures for the year ended May 31, 1911, the yield of copper being $2\frac{3}{4}\%$ as compared with 3%, and that of gold $8\frac{3}{4}$ dwt. as compared with $10\frac{2}{3}$ dwt. On the other hand, the ore treated in the chlorination plant averaged nearly 10 dwt. gold as compared with $9\frac{1}{2}$ dwt. The explanation of the decrease in the quality of the smelting ore is that stoping is now done in such a way as to prevent falls of rock and other accidents. Important modifications are being made in the smelting operations, for it has been found that by the recent introduction of sulphide fluxing ore from the Many Peaks mine in place of the barren oxide iron ores from Iron Island, it is possible to adopt pyritic smelting. A. L. Dean, of the Mount Lyell smelter, has made an examination and recommends certain necessary alterations. The old practice of producing first a low-grade matte and subsequently re-smelting so as to produce a grade suitable for the converter is being abandoned in favor of a single process. During the half-year the revenue from the sale of gold and copper was £452,336.

and the expenditure £381,730, leaving a balance of £70,606. A dividend of £50,000, at the rate of 1s. per £1 share, was paid in October last, and in order not to make a break in the distribution of dividends, £50,000 has been withdrawn from reserve and paid as a further dividend, bringing the total dividend for the half-year to £100,000, or 10% on the £1,000,000 capital. This course has been taken, as it is confidently believed that the decrease in yield and profit is only temporary.

NEW YORK

LATEST NEVADA-UTAH PLAN FOR REORGANIZATION.—LEWISOHNS AND LAKE COPPER.—GUGGENHEIM EXPLORATION REPORT.—GENERAL MARKET NEWS.

Nevada-Utah shareholders count the day as wasted which does not see the statement of some new plan for the reorganization of the company. The Stockholders' Protective Committee has formulated a scheme to issue \$1,500,000 shares of stock, par \$4, and \$1,000,000 in bonds, making a total capitalization of \$7,000,000; the new company to acquire the property of the old corporation and provide working capital; stockholders to pay an assessment of either 20 or 40c., as they may choose; those who pay 20c. to receive new stock, share for share against present holdings; shareholders paying 40c. to receive bonds in full for the amount paid in, and share for share of new stock as a bonus. On this basis there should be produced \$600,000 in cash, and \$400,000 in bonds left in the treasury. The debts of the old company aggregate \$200,000. The reorganization expenses are estimated at about \$50,000, on which it is calculated the new company will be enabled to start in business with a working capital of \$350,000. A New York Stock Exchange house has succeeded to the management of the Shareholders' Syndicate, which is opposing the plan above outlined. The Syndicate is now submitting a modified plan to the stockholders, calling for an assessment of 50c. per share; a bond issue of \$900,000, of which \$750,000 is to be sold at once, and a new stock issue of 2,000,000 shares, par value \$3. The Syndicate in conclusion works out its status of the new company to be called the Consolidated Nevada-Utah, which will be formed showing \$750,000 of bonds outstanding; bonds in the treasury to the amount of \$150,000; stock outstanding, 1,650,000 shares; stock retained for bond conversion, 300,000 shares; cash in the treasury (estimated), \$390,000; from all of which it may be noted that the shareholder is expected to pay the bill, in reality the principal item. Judgments are piling up against the old company, and the shareholders must use a great deal of cold-blooded analysis in order to determine whether they are not repurchasing their equity in the properties at considerably more than their real worth.

There was a good deal of comment recently when the formation of the board of the Inspiration Consolidated showed a strong representation from the Lake copper country. Now it appears that the tide of invasion may be turned in the other direction. Announcement has been made that the Naumkeag Copper Co. will be formed by the General Development Co. under the laws of Michigan, to develop a tract of land comprising 1200 acres on the south side of Portage lake just west of Houghton. The property embraces 1200 acres and includes the Dakota, 200 acres; the South Side, 200 acres; the St. Marys Mineral Land Co., 160 acres; the Naumkeag, 400 acres; the Pacific, 140 acres; and the Sheldon Douglas, 160 acres. The whole territory is practically virgin ground. The management will be under the direction of J. Parke Channing, and the first work will be a thorough exploration by diamond-drills, which, if satisfactory, will be followed by immediate sinking of shafts and further opening of the ground. The entry of the Lewisohns into the Lake Copper Co. is a rather important move, and is undoubtedly due to the work which Mr. Channing did last year, in connection with the attempted Calumet-Hecla consolidation. Another new Lake Superior copper flotation will probably be brought out within a short time, covering some 2000

acres of land about six miles south of the Mayflower, the preliminary exploratory work to be carried on with the idea of picking up the southerly extension of the Mayflower lode.

The regular chain of Guggenheim dividends has been declared. The report of the Guggenheim Exploration Co. is interesting, as showing the holdings of this concern in the various subsidiaries, and the appraisal value attached thereto, as per the following:

Assets: Treasury stock, \$1,206,700; American Smelters Securities Co., 'A' 154,000 shares, \$13,860,000; American Smelters Securities Co. 6% bonds at par, \$1,500,000; Esperanza, Ltd., 3016 shares, \$15,094; Utah Copper Co., 404,504 shares, \$9,161,767; Yukon Gold Co., 2,769,639 shares, \$9,883,088; Alaska-Yukon Properties & Equipment, \$1,170,230; miscellaneous investments, \$831,179; furniture, fixtures, and equipment, \$2704; bills and accounts collectable, \$121,483; cash and demand loans, \$7,721,033; total assets, \$45,474,178.

Liabilities: Capital stock, \$22,000,000; surplus, \$23,474,178; total, \$45,474,178.

An independent estimate of the value of Guggenheim Exploration stock, according to current quotation, is as follows:

American Smelters Securities Co. preferred 'A', 154,000 shares	\$13,860,000
American Smelters Securities bonds (\$1,500,000 at 103 ⁵ / ₈)	1,554,375
Esperanza, Ltd., 3016 shares at £1 16s. 3d.	26,513
Utah Copper Co., 404,504 shares at 57 ³ / ₄	23,360,106
Yukon Gold Co., 2,769,639 shares at 3 ³ / ₈	9,347,532
Alaska-Yukon Properties & Equipment	1,170,230
Miscellaneous investments	831,179
Cash and quick assets	7,846,120
207,033 shares at \$278.91	57,096,055

This book value of \$287.91 does not include the good will of the Guggenheim Exploration Co., which of very great value in mining enterprises. It will be noted that 404,504 shares of Utah Copper are carried on the books of the Guggenheim Exploration Co. at an average price of \$22 per share. The present market in Utah Copper is between \$58 and \$59, so that the profit on this item alone is a tremendous one. The ownership of this stock carries with it the Guggenheim holdings in Nevada Consolidated, which is held directly by the Utah Copper Co. In this way there is a further stock-holding that does not appear upon the Exploration company's books in any way, but which in case of liquidation would of course be subject to separate appraisal.

The Ray Consolidated stockholders have authorized the increase in the capital stock from 1,400,000 shares to 1,600,000 shares, and the Ray Central shareholders are now given the option to exchange their Ray Central stock for Ray Consolidated stock on the basis of eight shares for one. N. Bruce McKelvey, Felix Rosen of Hayden, Stone & Co., Keith Stewart, C. W. Peters, and P. A. Clark have been elected directors of the Ray Central company, the old board resigning. Chino is to be the object of some new financing; 50,000 shares of new stock will be underwritten by Hayden, Stone & Co. and offered to the shareholders at \$25 per share. Additional capital will be needed as a working fund in the first stages of production, and it is best to provide the funds in this way rather than postpone dividend payments until these requirements could be made up out of earnings. Both Ray Consolidated and Chino are now regularly listed on the Paris cote.

The Phelps-Dodge interests have never figured very largely in the present movement toward acquiring additional properties, and, like the mining properties controlled by W. A. Clark of Montana, have always been regarded as independents; that is, free from any numerous affiliations. The trend of affairs, however, is apparently to have its influence upon the Copper Queen owners. It is stated upon pretty good authority that negotiations are on foot for the acquirement of the Shattuck-Arizona. The James J. Hill people are said to be heavily interested in

the Phelps-Dodge company, and it is thought that Louis Hill has been picking up some Shattuck-Arizona, probably for the Phelps-Dodge interests. The rumor is borne out in part by the fact that, although plans were completed for a smelter for the Shattuck-Arizona some time ago, nothing has as yet been done, and the property is practically idle. The Shattuck-Arizona has developed some very rich orebodies, but in size is hardly sufficient to warrant the erection of a smelter such as would be necessary for profitable operations on Shattuck ores alone. The Phelps-Dodge output for February was hardly in line with general expectations. The increase in output has been anticipated all along the line, but the Copper Queen people produced 10,742,950 lb. of copper, this being quite a little less than was produced the previous month, or in February one year ago.

For some months shareholders in the La Rose Consolidated have been endeavoring, under the leadership of E. P. Earle, to secure some distribution of the cash surplus which the company has accumulated. Some two years ago or more the directors cut the La Rose dividend from 16% to 8%, since which time the company has accumulated more than \$1,000,000. D. Lorne McGibbon, president of the company, has insisted upon keeping the treasury fund intact, and Mr. Earle, having concluded that his efforts in behalf of the shareholders were futile in this regard, resigned from the board of directors.

ST. PETERSBURG, RUSSIA

CONTROL OF THE MARKET BY EUROPEAN SYNDICATE.—RELATION BETWEEN PRODUCTION AND PRICE.—CAUSES OF FLUCTUATIONS.—DOMESTIC REFINERY.

Russia, rejoicing in her platinum monopoly, is very much exercised on the question of making this monopoly something more than natural. It has been a source of great vexation to nearly all leading Russian industrialists that the metal should simply be mined in the Urals and sent away half washed to western Europe to become the plaything of syndicates there that have had, practically nothing whatever to do with getting it out of the ground.

The methods by which these syndicates have obtained control of the platinum situation is now sufficiently notorious and need not be further referred to. It is known that, whether these methods were wise or unwise, they were, at all events, effectual, and the platinum industry of Russia is really a foreign concern except in respect to getting the metal in semi-erude form from the sand, which is a simple operation for the most unsophisticated workman. It seems strange that a metal that could be so completely under the control of the Government, or even of a local combination of producers, should be the subject of such violent fluctuations in price. We find, for example, that in the year 1900 the price of platinum per pood (one pood equals 32.7 oz.) was 14,193 rubles for 83% metal, or 17,100 rubles for 100% metal. The corresponding price in Germany was 19,337r. per pood. This price remained practically stationary until 1904, when the 83% metal, which is the standard by which it is sold on the leading Russian precious-metal exchange (namely, Ekaterinburg), made 15,429r. per pood, rising to 17,435r. per pood in 1905, then careering through 1906 on to 34,000r. per pood in the month of October and declining to 29,560r. per pood in the month of December—the year averaging 23,000r. per pood. Then in 1907, after dropping to 21,120r. per pood in May, rising to 24,576r. in June, and reaching the nadir for the year of 17,764r. per pood, it averaged practically 20,000r. July 1908 showed a further decline to 14,208r. per pood, with a slight rise toward the end of the year, but finishing with an average of 16,500r. per pood; 1909 found the average 19,814r., 1910 showed platinum to have reached an average of 27,455r., and in the year 1911 the record price of platinum was registered, namely, 10 rubles 10-25 kopeks per zolotnik, or about 39,200r. per pood.

Now, as the production at the mines did not vary in anything like these proportions throughout the whole period

under review, and again in the first four years 1900-3 the production did vary very considerably while the price remained practically stationary, and while again in 1906, when the production showed a marked increase, the prices instead of falling rose considerably, followed by a serious decline in price in 1907 with an even more serious decline in production, while 1908 again shows an even greater decline still with a decline from 328 poods of 83% metal in 1907 to 298 poods in 1908, it will be seen that the rate of production bears no relation whatever to the rise or fall of the market, but that, on the contrary, the market rose as production fell, or it may be argued *vice versa*. All the same, when platinum was scarce as far as production was concerned, the market was falling, and when platinum grew plentiful the market rose. This might appear to be a natural sequence if the production had followed the market, but as these two phenomena were coincident we must look elsewhere for the reason. The cause was undoubtedly in the maneuvers of the western European platinum controllers, who simply ran the market up and down at their own sweet will as they found it convenient in order to boss the situation in the Urals.

It is quite likely that the following is the correct explanation of the present high level of platinum prices, though the situation is sufficiently complicated to make it very difficult to assign to any one of the causes of preponderating influence. First are the operations of the western European syndicate referred to above. Second, there is, it is to be feared, indubitable evidence that the platinum sands are becoming exhausted and other discoveries must be made if the world's demand is to be satisfied. The third is the growing demand, as shown not only in the natural increase in the consumption of platinum goods, but also in the increased demand in the jewelry trades, probably called into existence by the very reason of the appreciation in the price of the metal; and the fourth reason is the almost certain enactment of a Government law on platinum and the complete control of the industry in Russian interests.

I am disposed, at all events for the moment, to give the palm to the operations of the syndicate, whose policy it is to make the Russian platinum producer as comfortable as possible, that he may resent the paternal interference of the Russian Government. All other reasons given, which may or may not be permanent, although the obvious exhaustion of the sands must be called a permanent one, would not operate so directly, at all events so immediately, on the price of the metal as to raise it to its present dizzy height. But the next important factor is, without doubt, the growing conviction that the sands are rapidly being exhausted and the increasing doubt as to whether other useful deposits are going to be found. This appears to be the position of the platinum industry at the present day. Whether it will ever suit the convenience of the foreign syndicate to run the price down again will depend upon the firmness with which the Government proceeds with its new policy of holding the platinum industry both as a producing industry and a manufacturing or refining industry in the country itself.

The reasons for binding the refining industry to Russia are sentimental rather than material, for the small plant that is required to refine the small quantity of platinum produced, although it happens to be practically all that is produced in the world, will add but a few thousand rubles to the earnings of Russian workmen, and it may be that to the country generally this money will be lost in lack of efficiency in refining. But against this must be set the retention of the precious associated metals, such as iridium and osmium, in the country; but which are obtained by the western European refiners at no expense to themselves whatever, or nearly so. The probability is that the Government will proceed on its present lines and that with the demand always remaining a good one (the frequently announced successful alloys having all proved failures) the value of platinum will retain a good high level, if not its present one; and it may be prophesied that under the encouragement of the Government, with the necessary advances to producers from the Imperial Bank, the violent fluctuations in the platinum market quoted in the article will have become a thing of the past.

General Mining News

ALASKA

KUSKOKWIM

(Special Correspondence.)—Work was continued this past summer at Golden Gate Falls. H. W. Reeth built a new station about 55 miles northwest of the falls to be used as a supply station and stopping place while traveling. It is about at the head of navigation on this river. He spent considerable time on the northwest slope of the second mountain range and reports a great variety of rock, probably of Post-Jurassic age. He found a sheared zone following a diabase intrusion in contact with slate, and traced it over 18,000 ft. It is from 50 to 500 ft. wide, and in one place a body of mineralized rock is exposed for 100 ft. vertically. Two samples assayed \$2.40 to \$9.98 in gold with a trace of silver. Two miles below Golden Gate Falls he dug a ditch 1000 ft. long and late in the season ran through 5 cu. yd. of gravel, using two sluice-boxes, one 12 ft. and the other 10 ft. long and over 12-in. grade. No quicksilver was used, but 60 grains of fine gold was cleaned up. Half a dozen parties were mining this summer near the Tuluksak, but made slow progress on account of the water. One miner came down the latter part of August with \$900 worth of gold dust. A number of prospectors worked on the different tributaries of the lower Kuskokwim, and five miles below Quinhagak three drills were testing dredging ground. The men in charge report encouraging prospects. Gold is also said to occur on the beach between Cape Newenham and Cape Peiree. In what quantity is not stated. One great drawback to prospecting in this area is the high retail price for dynamite; No. 2 sells in Nome at 17c. per pound, and the Kuskokwim Commercial Co. at Bethel charges 50c. The prospector can never think of looking for any quartz vein with the price of powder what it now is. As a rule, he is a man with limited means and has to look for a placer ground and pass by the quartz leads.

Bethel, November 1.

ARIZONA

GILA COUNTY

(Special Correspondence.)—Besides the work of actual mining and underground development that is being carried on in the Miami district, another sign of the interest that is being taken by outside capital is the exploration by churn-drilling. Four companies are conducting this kind of exploratory work, with six churn-drills, all of 'Star' manufacture, in continuous operation. The Miami Copper Co. is working one drill northeast of the orebody in the vicinity of No. 3 shaft, on ground whose surface indications are considered very favorable for the development of another body of ore. The New Keystone Copper Co. is operating one drill northeast of the shaft. The Southwestern Miami Development Co., whose property lies to the southwest of, and adjoins, that of the Live Oak Development Co., is running two drills and intends to add another as soon as possible. The Lewisohns, who have an option on the Barney group, west of, and adjoining, the Live Oak, are operating two drills. In addition to these, others may be added in the near future. The Miami mine continues to produce at the rate of 3000 tons per day, all of which is readily handled by the concentrator, which is now in full operation. In the sixth unit of the concentrator, F. W. Solomon, the mill superintendent, is experimenting with the view of introducing graded crushing to a greater extent than is now practised and also the roughing system. An additional water-supply is being developed by air-lift wells on the company's ranch near the pumping station at Burch, about four miles from the mine. The work of enlarging shaft No. 2 at the Live Oak mine from 2 to 3 compartments, is proceeding rapidly and is expected to be finished this month. The surface equipment is being erected at the same time. The Southwestern Miami Development Co. hole No. 2 is 875 ft. deep. Ore is ex-

pected within a comparatively short distance. Hole No. 3 is 125 ft. deep. Hole No. 1 on the Barney group, under option to the Lewisohns, is 1175 ft. deep. Hole No. 2, near the Live Oak boundary, is 130 ft. deep. It was near this hole that a hole drilled by the Barney Copper Co. is reported to have cut ore at a depth of 500 ft., penetrating it for a distance of 20 ft. before it became necessary to abandon the hole on account of caving. At the Superior & Boston, development work continues on the 12th level. W. G. Rice, president of the company, is now at the mine. W. H. Aldridge, L. D. Ricketts, and W. D. Thornton, vice-president of the Inspiration Con. Copper Co., are visiting the mines and are in conference regarding the construction of the mill and other important matters.

Globe, March 14.

PIMA COUNTY

Operation is to be resumed in the near future at the Gould mine, 11 miles west of Tucson, according to a recent report. The mine is owned largely by the Pioneer Smelting Co. The Pioneer company's new smelter is almost completed. About 50 tons of ore per day is being stored at the plant. The Southern Pacific railroad recently published rates to the smelter from nearby points. From Patagonia, the rate on ore less than \$15 per ton in value is \$1.50 per ton. From Vail, Calabasas, and nearer points the rate is \$1 per ton.

YAVAPAI COUNTY

Press rumors from Prescott state that the Tiger Gold company, operating the Grey Eagle and Oro Belle claims, is planning extensive additions to its plant. The Ruth mine, near Prescott, owned by J. I. Gardner and James Slack, has a carload of ore ready for shipment to Pueblo, Colorado. It is reported that a stamp-mill will be erected on the Juanita company's property, in the Crook canyon district. C. E. Warren is superintendent for the company. A large quantity of telluride ore has been blocked. Reports from Prescott state that the vein assays \$24 per ton.

CALIFORNIA

NEVADA COUNTY

Recent reports state that the shaft of the Golden Gate mine, now down about 900 ft., is being sunk at a rate of 150 ft. per month. The 10-stamp mill of the property is in steady operation. W. P. Martin, superintendent of the property, states a Grass Valley rumor, is about to order more machinery for the mine.

PLACER COUNTY

The Beaver Gold Dredging Co.'s dredge at Loomis, which sunk recently when a leak was sprung at the stern, has resumed operation. The dredge settled to the bottom of the 14-ft. pond at 5 p.m. Wednesday, February 21, and was in operation at 7 a.m. the following Saturday. S. B. Dunton, superintendent for the company, had charge of the floating of the dredge.

SAN FRANCISCO COUNTY

The San Francisco chapter of the American Metallurgical Society on March 13 discussed the resolutions adopted in February against J. E. Raker's bill for Government free assaying and testing laboratories. The trustees of the State Mining Bureau have asserted that by such establishments promoters would be able to display Government assay certificates as for samples from their mines, and that an office for qualitative analysis is maintained in San Francisco, obviating the necessity for a Government station at Auburn.

SHASTA COUNTY

(Special Correspondence.)—Adit No. 5 at the Mammoth mines is in 2455 ft. It is 9 by 10 ft. and will be used as the main working-level. A 700-ft. drift connects the new adit with the old workings. The company is installing electrical automatic bag-shakers at the bag-house, replacing the levers formerly used for this purpose. The ninth section of cooling pipes is nearing completion. This gives a total of 45 cooling pipes, employed in reducing fume temperature before the smoke passes into the bag-house. The Afterthought Copper Co. is reported to be consider-

ing the erection of a zinc-extraction plant at Ingot. The company has developed a good body of ore in its mines, but the presence of large percentages of zincblende has made the smelting of ore difficult. J. H. Bull is superintendent. It is said the long-projected railroad from Ingot to Bella Vista, a distance of 12 miles, will be completed this year. The Noble Electric Steel Co. is placing its furnace in condition to resume production of pig iron. E. P. Conner confirms the sale of his Grand Central claims to the Victor Mining & Power Co. The property is situated near Harrison Gulch.

Redding, March 11.

SISKIYOU COUNTY

(Special Correspondence.)—The North American M. & D. Co. is arranging to erect concentrating equipment and a cyanide plant at the Mono mine, near Yreka. A large reserve of ore has been opened between the fifth and sixth levels, and deeper development is planned. About 25 men are employed, and the company has expended about \$35,000 in development and equipment since last July, when the mine was acquired. The Mono has a productive record of \$300,000. The main offices have been removed to Yreka. S. J. Silva is general manager, and Ernest Harrison secretary. Shepard & Co. are opening a group of claims containing gold and copper ore. In the Humboldt district much quartz mining is under way at the Flag, Conservation, and other small properties. Redding people have taken over the Cape mine, Yreka district, for a reported price of \$40,000. The group embraces six claims, of which three are patented. Harry Doggets reports the discovery of an 18-in. vein of \$30 ore on Barkhouse creek, about 12 miles from Yreka.

Yreka, March 9.

TRINITY COUNTY

A report from Trinity Center says that Angelo Belli, after taking \$25,000 in one week from his claim last fall, sold the claim to San Francisco investors for \$25,000 six weeks ago, as he thought he had exhausted the property. The purchasers have taken \$17,000 from the mine, and expect to obtain much more valuable ore.

TUOLUMNE COUNTY

(Special Correspondence.)—It is reported that the management of the Harvard mine is considering the erection of a cyanide plant.

The old Mammoth works, near Jacksonville, are coming once more into prominence. Connections for electric power have been made, and the mill, which is being repaired, is about to start. Fifty stamps are now dropping at the Shawmut. At the If I Can mine, on the Stanislaus river, 20 men are at work. Grading for two big water tanks is in progress. The mill will handle 200 tons of ore per day. The new adit, which is about 400 ft. long, will be sent in about 1500 ft. to cut the main channel. At the Nonpareil, near Big Oak Flat, a mill test is being made of 300 tons of ore. Results will determine the future line of action of P. G. Gow, who holds the property under bond. An inspection of the Rising Sun mine, near Arastaville, was made this week by San Jose capitalists, who intend starting work shortly. New orebodies of unusual size and good grade have been discovered at the App mine. It is definitely announced that the famous property is about to change hands. A week's clean-up at the Gem mine, owned by J. F. Wulzen, near Confidence, has amounted to over \$2000. One hundred and sixty acres of the old Pereira orchard, at Janestown, which is interlaced with a network of gold-bearing veins, is to be developed by Pennsylvania capitalists.

Tuolumne, March 11.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Work has been resumed on the Shigley property on Griffith mountain. A streak of ore 6 in. wide is showing that is worth \$24 per ton in gold and silver. A carload shipment of ore will be made from the Pulaski mine on Leavenworth mountain next

week. The ore will be sent to Denver for testing purposes to determine the best method of treatment. When the report is made, work will start on a 50-ton mill. B. F. Kelly is manager. The Pixley and Aunt Jack mines on Saxon mountain have been taken over by McDonald & Poindexter of Seattle, Washington. Work will soon be resumed by the Gold Fissure M. Co. The property is situated on Silver mountain. Willis Bristol is manager.

Georgetown, March 9.

GILPIN COUNTY

The Black Jack mine recently shipped from its 100-ft. level four loads of ore from which \$22 per ton was received. A raise is being driven to connect with the 140 and 100-ft. levels, and development will be pushed on the former level. E. Perley is superintendent of the mine. The shaft of the Coaley mine, of which Mr. Perley is superintendent, has been retimbered to the 200-ft. level, and some high-grade silver ore has been found. The latter mine was recently opened after having been idle for a number of years. From the Topeka mine about 80 tons of ore per day is being shipped to the Iron City mill for treatment. Development will be resumed soon at the Illinois and Edinburg mines on Quartz hill by Young & McGruder of Denver. The property of the Fifty Gold Mines Corporation will be sold at public sale April 17.

OURAY COUNTY

The Camp Bird, Ltd., has paid its regular quarterly dividend of 2s. per share on the 1,100,051 shares of stock outstanding, making a disbursement of \$550,026. This brings the total disbursement in dividends by the London company, since 1901, to \$8,470,152. A number of snowslides aroused some excitement in the district recently, and some railroad laborers were killed, but little damage was done to property. The boiler and boiler-house of the Atlas mine were moved about seven feet, putting them temporarily out of commission. The Camp Bird mill was not damaged.

SAN JUAN COUNTY

The zinc plant of the American Zinc Ore Separating Co.'s Sunnyside mill at Silverton has been put in operation. Louis Schafer is in charge of the new plant.

INDIANA

LAKE COUNTY

The International S. & R. Co. is about ready to let the contract for the construction of buildings for its proposed lead refinery at East Chicago, 24 miles from Chicago, according to an announcement by E. P. Mathewson. The company has bought a tract of land along the canal connecting Lake Michigan and the Calumet river. The site has good railroad facilities. The proposed plant is to have a capacity of 3000 tons per month and is to be completed in six months.

NEVADA

ESMERALDA COUNTY

The Goldfield Merger Mines Co.'s shaft on the St. Ives claim is down 750 ft., and is being sunk at the rate of 140 ft. per month, states a recent Goldfield report. It is probable that the rate will be increased to 150 ft. per month. The shaft has penetrated two bodies of quartz, which, while not of profitable grade, will be prospected later by lateral development.

The Goldfield Con. Mines Co. has declared its regular quarterly dividend of 30c. per share, and the customary extra quarterly dividend of 20c. per share, payable April 30 to stockholders of record March 30.

NYE COUNTY

In the week ended March 9 a total of 9072 tons of ore was produced in the Tonopah district. The production of the various companies was as follows: Tonopah Mining, 3550 tons; Belmont, 2250; Montana Tonopah, 962; Tonopah Extension, 1015; West End, 775; and the MacNamara, 520 tons of ore. The estimated value of the whole production was \$226,800.

The profit of the Tonopah Belmont company for Feb-

ruary is reported at \$165,632. The company produced 9813 tons of ore, of which it milled 7642 tons and sent the rest to the smelter. The gold produced amounted to 3891 oz., and the silver to 374,973 ounces.

The Montana Tonopah has intersected a 2½-ft. vein of valuable ore on the 615-ft. level. Development is to be resumed at the Wandering Boy shaft of the Jim Butler property. An electric hoist will be installed.

STOREY COUNTY

In the Con. Virginia mine during the week ended March 9 the 3-compartment raise from the 2400-ft. level was carried 9 ft. and timbered. From this work 34 cars of ore valued at \$1112 was saved. The Ophir company produced during the week 247 tons of ore, valued at \$7618, and also shipped 329 tons of ore to the Kinkead mill. The Mexican mill, running 88% of the time, treated 482 tons of ore, of which the gross assay value was \$12,021. The Union Con. extended the west cross-cut from the winze used jointly with the Sierra Nevada, for 52 ft. Timbering was not needed. The Mexican cleaned out the north drift from the winze, and is clearing a heavy cave, south of the line between the Mexican and Union mines. The Crown Point produced 660 cars of ore, valued at \$4637. The pumping report showed the level to be below the 2500-ft. level of the C. & C. shaft. The Yellow Jacket mill resumed crushing Jacket dump ore. The usual repairs were made in the mine.

NEW MEXICO

SOCORRO COUNTY

The new Socorro power-plant is operating both mine and mill. The full mine-crew is again at work. A crack in the crank-shaft of the oil engine at the Deadwood Mines was discovered last week, and the mill is temporarily closed pending replacement of the defective part. Development will continue in the mine, hoisting being done by gasoline engine. The Ernestine M. Co.'s ore treatment last week was 640 tons. Bullion for the second 10-day period of February amounted to 7675 oz., with a concentrate product of 11,000 lb. The second 10-stamp Allis-Chalmers battery was started on February 26. The Deep Down lessees have installed a temporary gasoline pump in the adit and unwatered the winze, where good ore has been discovered. The Deadwood mill will handle the product. The Oaks Co.'s winze in the Pacific adit has intersected high-grade ore in limited quantity. There are indications of a rich ore-shoot below this point. Work is going on in the South shaft and also the drift from the North shaft.

Mogollon, March 1.

TEXAS

LLANO COUNTY

N. J. Badu, of Llano, and associates, who are extensively interested in iron ore deposits in the Llano district, are preparing to erect a hydro-electric plant for smelting purposes. Mr. Badu claims that the electric process he plans to use is not only feasible, but that its practicability has been proved in Sweden. It is planned by Mr. Badu and associates to erect a large dam across the Colorado river at a point about 12 miles from Llano to form a storage reservoir which will give a water-supply for generating the electric power. The iron furnaces will be situated near the plant.

The Llano Gold & Rare Metal M. Co., which placed its 50-ton reduction mill in operation at its Heath mine, north-east of Llano, a few weeks ago, is preparing to double the capacity of the plant. This mine is a gold producer and the mill is said to be the only one of its kind in Texas. It has been running day and night since the completion of the pipe-line by which it was provided with the necessary water supply, and has a capacity of 50 tons of ore per day. The company owns 200 acres adjacent to the mine. Recently representatives of a Chicago syndicate visited asbestos properties near Llano and after an investigation made a favorable report on them. The Chi-

cago syndicate has obtained control of the deposits and will soon begin mining operations, it is announced.

UTAH

JUAB COUNTY

The Iron King Con. M. Co. has stopped operation, owing partly to failure to secure advantageous ore contracts, it is reported. C. E. Loose, general manager, stated that the management has not abandoned hope for precious metals under the iron orebodies developed by the company. When the sale of iron proves sufficient to meet the expense, exploratory work will be started. During 1911 the adit was extended 840 ft. Assessment No. 6 will meet all obligations and leave a balance.

The Grand Central shaft has reached a point 25 ft. below the 2300-ft. level and the work of cutting a station on that level is under way. With that completed driving will be started. Good ore was found at the 2200-ft. level and in a 40-ft. winze sunk from that level. The shaft last month was sunk at a rate of 108 ft. in 30 days. New shaft timbers are being placed in the Black Jack mine, preparatory to resuming development in the Star Consolidated part of the property.

TOOELE COUNTY

The second furnace of the lead smelter at the International S. & R. plant at Tooele is to be started in the near future. As soon as the business warrants it, more blast-furnaces will be erected, says a recent announcement. The company is reported to have a stock-pile of 60,000 tons, and contracts to come in force May 1 will provide ore in excess of the plant's capacity, 500 tons.

UTAH COUNTY

The directors of the company operating the Dream mine, near Salem, recently decided to install machinery to rush development. Twenty men are employed, being paid in stock. Lars Olesen is superintendent of the property.

To facilitate development at the Dream mine, near Spanish Fork, machinery will be ordered, and an adit driven to tap the bottom of the workings. Lars Oleson is superintendent for the company.

CANADA

BRITISH COLUMBIA

For the first time in many months the Granby smelter is running at full capacity. In January the company produced 1,607,558 lb. copper, 29,693 oz. silver, and 4440 oz. gold, against a production in January last year of 1,758,518 lb. copper, 33,730 oz. silver, and 4426 oz. gold.

ONTARIO

The directors of the McKinley-Darragh-Savage mines are considering the construction of a wire-rope tramway to deliver ore from the Savage mine to the McKinley mill. Coarse crushing and regrinding of the oversize, as employed at the mill, has been notably successfully, as has the by-passing of primary fine for treatment in independent units.

QUEBEC

The La Compagnie des Champs d'Or de Rigaud-Vaudreuil, with offices at 107 St. James street, Montreal, has secured a concession of about 70,000 acres south of the St. Lawrence, in the central part of the province, says G. Willrich, consul at Quebec, in the *Daily Consular and Trade Reports*. The company has completed extensive preparations for resuming hydraulic mining on a large scale. It started operation in 1911, but was troubled by lack of water. The company secured machinery from the United States, and has in its employ Californians experienced in this class of mining. While Quebec has not produced gold in recent years, recent quartz discoveries have caused the Bureau of Mines to organize an exploration party to investigate the northeastern part of the province.

YUKON

The Canadian Klondike M. Co. has ordered from the Marion company a duplicate of its 16-in. ft. dredge, the

Canadian, now operating near Dawson. The new machine is to be completed in four months, and it probably will be assembled on the Boyle concession, says a news despatch from Dawson. Charles Boyle is resident manager for the company at Dawson.

MEXICO

SONORA

It is reported that the Pedrazzini Gold & Silver M. Co. probably will close the Las Chispas mine, near Arizpe, on account of labor troubles. The miners decline to submit

MILL OF PEDRAZZINI G. & S. M. CO.

to the searching process which the company instituted to stop 'high-grading.'

Press reports state that the freighting contract has been let for the delivery of the machinery of the new reduction plant of the Richfield Copper Co. The mill will be erected on the property, about 45 miles from Querobabi, the station where the machinery now is. J. A. Cooper, general manager for the company, recently returned to Nogales, Arizona, after an inspection of the property.

Reports from Navajao state that the Promontorio mine, which has been shut down for several years, may be reopened in the near future. It is rumored that machinery soon is to be ordered for the South Sonora Silver M. Co. property in the Promontorio district. W. G. Du Bes is manager for the company. The Plata Fina M. & O. Co. has its shaft down 108 ft., in good ore. The property, which is in the same district, is in charge of T. P. Brinegar.

PHILIPPINE ISLANDS

(Special Correspondence.)—Mining in the Philippines does not amount to much. The Headwaters property is closed temporarily on account of several typhoons in succession, that smashed things up generally, and of a painful lack of cash at the same time. Dredging has had a small run of luck lately, but nothing worth mentioning until it is seen whether or not the properties will pan out equal to expectations. Sixty-odd inches of rain has fallen in seventy-two hours, and several of these showers occurred in quick succession, so that transportation and everything else is badly smashed.

This country has suffered from the rankest kind of wild-cattening and also from extremely bad engineering, or no engineering at all. There are some good properties, and eventually some of them will become steady producers, but it will take a new generation of capitalists and operators to make them. Mining is expensive, owing to local conditions in many places and also owing to the character of the deposits, which are generally lenticular, with spotty ore in big soft veins that take a lot of timber and careful mining to handle.

Manila, February 8.

Among the Copper Mines

THE PHELPS-DODGE SMELTERS in February produced 10,724,950 lb. copper, compared with 11,423,100 in January.

The CALUMET, ARIZONA, smelter turned out 4,432,000 lb. of copper in February, as compared with 4,544,000 lb. in January, and 3,570,000 lb. of copper one year ago.

The INSPIRATION CONSOLIDATED offering of convertible 6% bonds met with flattering success; 99% of the bond issue is reported to have been taken by the shareholders.

THE SHANNON COPPER CO. in January produced 780 tons of copper, the largest month's production for the company since 1907. It is reported that the company is planning to exceed during 1912 the production for last year by about 3,000,000 lb. The Leonard Copper Co., a subsidiary of the Shannon company, is shipping about 5000 tons of ore per month to the Shannon smelter.

The CALUMET & HECLA M. Co and its subsidiary companies in February produced 10,803,641 lb. of copper, it is estimated, as against 10,796,956 lb. in January and 11,125,979 lb. in December. The total estimated production in pounds of the Calumet & Hecla and subsidiary companies for the past two years is as follows:

	1912.	1911.	1910.
January	10,796,956	10,684,785	11,651,527
February	10,803,641	10,235,801	11,358,545
March		10,030,364	12,277,142
April		10,732,707	11,115,793
May		12,190,543	10,975,331
June		11,515,759	10,742,250
July		10,551,847	10,507,713
August		11,374,064	10,628,106
September		10,596,233	9,842,635
October		10,676,411	10,774,602
November		11,608,122	11,800,263
December		11,125,979	11,253,933
Total		131,322,615	131,927,840

February Copper Review

By MISHA E. APPELBAUM

From February 8, when the January statistics were announced, until March 9, copper has ruled very firm, and closes at 14⁵/₈¢, per lb., delivered 30 days, for electrolytic and 14³/₈¢, per lb. for lake. The statistics for the month of February were in line with what most of the producers expected, but the decrease was about 20,000,000 lb. less than I estimated. The domestic deliveries were very low at 56,000,000 lb., and the exports fell to 63,000,000 lb. It may be that, due to the strikes abroad, the full quantities of copper contracted for were not shipped, and if such is the case, then the exports for the present month will be so much greater; that is, of course, supposing that the coal strike will be settled during the next few days. The visible supply in this country now is about 66,000,000 lb. However, there has been quite a change in the financial district and a slight improvement can be noted in most lines, with every indication that the improvement may go further. Should this materialize, I am afraid a runaway copper market might develop. A visible supply of 66,000,000 lb. of copper is none too large, and is a very small one with which to enter upon a period of business expansion. One thing appears to be certain, that the low copper prices which have existed for the past few years will not again be witnessed for some time to come, and that the average price of copper during the present year will be nearer 15 than 13¹/₂¢, per pound. A steady market at that level would be desirable to all concerned, as it would not interfere with the consumption, and would leave a good margin of profit to the producers.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

VICTOR BARNDT, of Tonopah, is in San Francisco.

A. DEWINT FOOTE was in San Francisco last week.

F. L. SIZER has gone to Calaveras county, California.

T. A. RICKARD is expected in San Francisco tomorrow.

FRED H. REECE has left southern Colombia for New York.

S. F. SHAW has left New York and is now at San Antonio, Texas.

SUMNER S. SMITH has returned to Juneau from Fairbanks, Alaska.

ROSS B. HOFFMANN and CHARLES JANIN leave San Francisco today for London.

C. W. KNIGHT was married to Miss GRACE E. HEWSON, at Toronto, on March 2.

C. W. BOTSFORD has been inspecting properties in the Kelly district, New Mexico.

ROBERT E. CRANSTON has opened offices in the First National Bank building, San Francisco.

DRUMMOND MACGAVIN will leave soon for Spitzbergen, where he will assist SCOTT TURNER.

A. H. CASE is manager for the Tennessee Copper Co., instead of acting manager as formerly.

VICTOR C. ALDERSON, president of the Colorado School of Mines, spent February 23 and 24 at Telluride and Ouray.

J. H. THELLER has accepted the position of superintendent of the River Bed mine, Walker, Siskiyou county, California.

T. LARSEN, of the Waihi Gold Mining Co., has left Sydney for Siberia, where he joins the staff of the Spassky Copper Mining Co. at Akmolinsk.

E. A. JULIAN, general manager for the Nevada Hills Mining Co., who has been ill in San Francisco, is convalescent and is now visiting friends at Mare Island.

FRANKLIN GUITERMAN has been made technical director for the Guggenheim interests, with an office in New York. The work in Colorado will hereafter be in immediate charge of L. G. EAKINS.

Obituary

GEORGE OSLER SMART, who died on November 29, 1911, at the age of 47 years, though a comparatively young man, had long been prominent in South African mining affairs. He went to Natal from his home in Scotland in 1881, and in 1888 went to the Rand, where he was successively with the George Goeh and Simmer & Jack companies, being at the time of his death reduction works manager for the latter company. He was considered one of the best millmen on the Rand and had a prominent part in the development of the methods of South African metallurgy.

WILLIAM CHATTIN WETHERILL, an engineer and metallurgist best known for the prominent part he took in the development of the metallurgy of zinc, died of heart failure at Denver, on February 10, at the age of 60 years. A graduate of the Polytechnic College of Philadelphia, he engaged in railroad construction in America, later going to Brazil for railroad surveys along the Amazon, and upon his return engaging in surveys for the Northern Pacific; later he was chief engineer of the Mexican Central railroad. In 1889 he was appointed general manager for the Empire Zinc Co. at Joplin, and in 1901 he became vice-president of the Empire Zinc Co., at Canon City, Colorado, for which he was also consulting engineer; these positions he held at the time of his death. He was well known throughout the metallurgical world, and leaves many friends. He was the son of Samuel Wetherill.

EDITORIAL

MEXICAN conditions continue extremely unsatisfactory, and to none more so than the mine operators who see silver mounting in price while their mines are perforce idle.

ANNOUNCEMENT that Mr. George W. Perkins has bought control of the New York *Evening Mail* suggests that the desire for publicity may sometimes even lead to the ingestion of indigestible wood-pulp.

EUROPEAN banks have increased their holdings of gold during the past five years by \$500,000,000; a little less than one-quarter of the total gold production of the world during that period. The amount consumed in the arts, accretions to the treasuries of the nations, and to private banks and individuals, go to make up the difference.

TRANSFER to America of art collections owned by Mr. J. P. Morgan should elicit only approval. European cities naturally regret their loss, but it is not possible to sell cake and have it to eat as well. Exhibition of the collections in the second largest city of the world will make them accessible to a larger and no less appreciative public, and Mr. Morgan deserves compliment in procuring for the people an educational advantage that, though needed, was not likely of realization by public initiative.

DESPATCHES from Seattle announce a rush of men and material from that port to Alaska, in anticipation of the spring thaw, which renders the trails to the interior impassable during the transition from winter to summer. The stampede of early spring and the exodus of early autumn are characteristic and iterative episodes in the life of the Far North. They reproduce annually some of the features of the old days when the spirit of adventure was gay and unsoiled, of the days when the West was all on the frontier, when the world was young and life an epic.

FREE SUGAR and pension increases are to be made possible by the excise tax bill which passed the House on Tuesday, according to the Democratic program. This provides for an income tax on all incomes of \$5000 per year, or over, including salaried persons, though nominally a tax upon the privilege of doing business. One result of carrying out these proposals is clear: radical readjustments of our social and economic relations will be made necessary, and Congress might well consider first whether the possible advantages to be gained will compensate for the inevitable cost of readjustment. But the Congressman with one ear to the ground is naturally unable to see very far.

PATENT laws in the United States are in a notoriously unsatisfactory condition, and the recent decision of the United States Supreme Court will not contribute to their popularity. The maker of a mimeograph decided to sell his machine at low profit, but imposed as a condition that the buyer should use only a specified brand of ink which the maker of the mimeograph manufactured and upon which the profit was large. The court held that the manufacturer was not only within his rights in imposing this condition, but might impose others as well. The possible results of

this decision are startling, and we shall wait anxiously to know whether users of vacuum or other patent filters are to be required to buy only certain brands of overalls, and to wear silk hats while working.

CONVICTION of Mr. George Graham Rice and his associates is principally important in that it establishes criminal responsibility for what has been commonly considered heretofore punishable only by civil action. It is interesting to note that men can be sent to prison for what is not legally a crime in most states, and only becomes a crime when the mails are used as one of the means to inveigle money from the pockets of the unwary. Many of the worst frauds are perpetrated without recourse to the mails, so while the decision is of large import and will make it easier to prevent many frauds, state legislation is necessary if complete reform is to be effected.

ORGANIZATION of a central body to keep in touch with associations and chambers of commerce throughout the country, and to represent commerce in its relations to the national Government, was effected at Washington recently. The suggestion came from the President, and invitations to the conference have been widely extended. In the United States, chambers of commerce have heretofore had no official standing, being purely volunteer organizations. In England the Board of Trade is a body of large powers, and in Germany and elsewhere on the continent there are close relations between the commercial organizations and the Government. In Japan, directors of each chamber of commerce are elected by popular vote, and it may interest the suffragettes to learn that women property holders are qualified voters. More and more governments are becoming agencies for securing social justice and commercial well-being, and the conference at Washington should be productive of much good.

ONE of the interesting suggestions of the week is that made by Mr. Walter Fisher, Secretary of the Interior, that the men and machinery which will be thrown idle by completion of the Panama canal, be shipped to Alaska and utilized in building a railroad from Seward to Fairbanks. This is in line with his earlier suggestion that the Government open a colliery in the Alaska coalfields and supply the necessary transportation facilities. We have already indicated our approval of the general scheme. The Secretary now points the way to practical work. The development of Alaska is a great national duty and a trunk-line railroad is the first desideratum. Rightly or wrongly, the old policy of Government guarantee of bonds of a private company, with or without a land grant, is now condemned. Private capital can not afford to do the work except on the basis of monopolistic exploitation. The Government has the trained men, the machinery, and the money. Why not give Alaska the same help as was given the Western states, though the means be in keeping with the times?

FINE ORE, when present in too large proportions, is often the *bête noire* of the metallurgist, interfering with the proper distribution of heat throughout the smelting column by occluding the passages through which the gases of combustion must pass, and producing an undesirable quantity of flue-dust that is even more difficult to treat than the fine ore from which it is derived. There appears elsewhere in this issue a classification, by Mr. Walter S. Landis, of all the processes that have been devised for the agglomeration of fine material of whatever nature. Mr. Landis is many centuries in error, however, in citing the briquetting of peat at Paris as the earliest example of the agglomeration of fine material, for, like many other useful inventions, it was known to the Chinese in

early times. Ibn Batuta, who in the fourteenth century followed in the footsteps of Marco Polo in his travels through Cathay, very clearly describes the making of balls of combustible material by the agglomeration of fine bituminous coal with a small percentage of clay as a binder, just as is still done in the cities of that country today. Origation is less to the point than application, however, and the metallurgists of recent years who have done so much to solve this difficult problem of the smelters' art have accomplished much more than had been achieved in all the centuries which preceded.

ENGINEERS are the men who, according to Wellington's definition, can do well with one dollar that which any bungler could do with two, after a fashion. This faculty of the true engineer can be exhibited in many ways, and often no more effectively than in economy of labor. This is well illustrated in the admirable contribution, by Mr. George Spence, to the discussion of the efficiency of native labor, which appears on another page. Too often an engineer who would be disturbed by the necessity for employing machinery of low efficiency is entirely unmoved by a 50 per cent efficiency foreman. This is not altogether unnatural; the efficiency of a machine is easily determined, but it is not practicable to obtain the indicator diagram of a foreman for comparison with ideal standards of efficiency. Mr. Spence's contribution is equally notable as an example of the valuable jottings of an engineer's notebook that escape becoming of service to the oncoming generation of engineers unless thus made public. Many men have neither the leisure nor facilities for preparing long technical articles upon a topic of interest, and others have valuable bits of experience to communicate which, from their nature, can scarcely be made the basis of an article. We hope that our readers will more and more recognize in our 'Discussion' columns a proper place for the publication of such suggestions, reflections, personal beliefs, and bits of experience as might otherwise never see the light of publication.

Cobalt and Its Future

The argentiferous deposits of the Cobalt district of Ontario are an inexhaustible source of interest to economic geologists. The association of a variety of silver minerals with arsenides and sulphides of cobalt and arsenic is unusual, though not unparalleled. Their mode of occurrence is equally interesting. Conglomerates, graywackes, and graywacke slates, forming the Cobalt series, rest unconformably upon a greenstone complex which is regarded as Keewatin. Both series have been intruded by a sill of quartz-diorite, which is nearly horizontal in some parts of the district, but steeply inclined in others. As soon as development of the mines had proceeded far enough to furnish evidence, considerable differences of opinion developed as to the nature and origin of these deposits, which have been studied, to some extent at least, by nearly all of the more prominent economic geologists, the most extensive work having been done by Mr. W. G. Miller, provincial geologist of Ontario, and his assistant, Mr. C. W. Knight, who in addition to field studies has, in conjunction with Mr. W. C. Campbell, made detailed petrographic studies of these ores. The most generally accepted opinion, if any one may be regarded as of general acceptance, is that ore-bearing fissures, due to contraction upon cooling after the intrusion of the diorite, have been filled by up-rising solutions subsequent to the intrusion. The diorite and the overlying Cobalt series was naturally more fractured than the generally underlying Keewatin; the conclusion was early reached that the fissures would extend to no great depth, tending to disappear in the Keewatin, and early de-

velopment tended to confirm this generalization which, in the form of an amusing verse, gained wide publicity.

With later work, increasing numbers of veins were found, both in the diabase and in the Keewatin, and recently, as recorded in our Toronto letter, the No. 9 vein in the Coniagas has been proved not only to persist, but also to be profitable in the Keewatin. Apparently the prospects in depth are not so hopeless as was at first supposed. Another view as to the origin of these deposits was held by the late S. F. Emmons, who in a notable paper published in this journal shortly before his death, advocated the hypothesis that the veins occurred in fissures of the ordinary type, their small size being due to their representing only the 'roots,' as it were, of larger veins formed in great thickness of overlying rocks. With this conception as a basis it is easy to ascribe the phenomenal richness of the veins to secondary concentration during erosion. This view also leads to a pessimistic outlook as to the ore-content of the Keewatin rocks. One swallow does not make a summer, and a few veins traced a short distance into the Keewatin cannot be assumed, after the fashion of promoters, to indicate that the ores extend to the *ewige tiefe*, but the outlook is at least now more hopeful. A district which has one producer of five and one-half million ounces of silver annually, a second of three and three-quarter million, and a third of nearly a million ounces, has established a place for itself among the great districts of the world, even if it should be subject to a too early decline. We hope the deep levels may prove unexpectedly remunerative, and that this district, of which the early days were youthfully spectacular, may have a succeeding period of quiet productive maturity.

The Canadian Mining Institute

By T. A. RICKARD

The recent meeting of the Canadian Mining Institute (at Toronto, March 6 to 8) must have left pleasant and enduring impressions on those who were in attendance. The three days devoted to the convention at the King Edward Hotel passed rapidly and profitably, affording opportunities neither too long to be tiresome nor too short to be hurried for discussion of technical subjects of immediate interest. The chair was occupied most worthily by Mr. Frank D. Adams, professor of geology and dean of the science department in McGill University. His presidential address was devoted to a most appropriate subject, namely, the service rendered to mining by the geologist. Several instances were adduced of the actual discovery of mineral deposits and the consequent birth of profitable industry due to the application of scientific observation in the field, notably the case of Cobalt, which owed its beginning to the detection of uncommon minerals by Mr. Willet G. Miller. Other instances, chiefly in the iron regions, were mentioned. I venture to add, however, that the first aid to mining on the part of the geologist is not often the most impressive, for the simple reason that usually he comes in the wake of the prospector; he does not precede him. Most of the big ore deposits of the world have offered a readily recognizable aspect to the first seeker that happened upon them, for example, the Comstock, Broken Hill, Mount Morgan, Goldfield, Calumet & Hecla. Not often is the geologist the first to arrive; he contributes intelligence to exploration, he unravels complexities, he gives the miner a chart underground, but his place is rarely in the forefront of mineral exploration. At Tonopah, Leadville, Cobalt, Nome, and Bendigo the conditions were not simple, and the miner stood with pick in hand until the student of nature overtook him on the trail; but this has happened rarely.

This address, the appearance of which in print will be

welcomed by my readers, was followed by the dry recital of statistics by representatives of various mining departments, and in the afternoon a series of papers on coal was submitted. These papers gave a vivid impression of Canadian fuel resources. According to Mr. D. D. Cairnes the quantity of coal in the Yukon alone is enormous; indeed, the sub-Arctic regions of the American continent appear destined, like Spitzbergen, to modify our ideas of essential cold. On the Pacific coast, as stated by Mr. H. Foster Bain, whose paper was read by deputy, the use of California oil is now general in maritime transport and the supply of Japanese coal suggests another fact affecting industrial expansion. This writer submitted several suggestive ideas in regard to the influence of the Panama Canal upon the trade routes of the world and outlined the far-reaching effects of the artificial union of the Pacific and Atlantic waterways. On the program Mr. Eugene Coste was set down for another paper on the "fallacies" of other people in regard to the origin of oil, but he did not appear, and so we lost a chance of seeing once again how oil does not smooth the troubled waters of disputation. That proverbially benign effect apparently is not a quality of oil having inorganic origin. At the evening session the sanitation of the miner's and metallurgical worker's environment was discussed in a lecture by Mr. W. H. Tolman. The relentless flow of his speech and the rapidity with which his magic-lantern slides succeeded one another on the screen were almost too much for any but the most alert of his hearers. I was again convinced that the magic lantern as an aid to exposition is overdone by my American friends. The picture thrown on a screen leaves no enduring image, it is erased from the memory by a rapid succession of similar pictures, and often tends simply to bewilder the mind with cinematographic phantoms. One or two photographic illustrations are a decided help to the lecturer, but an orgy of slides is tiresome. They leave confused impressions and detract from the value of the spoken word, which, skilfully used, should be a sufficient exposition. At the following morning session the principal papers were those of Mr. Robert H. Richards and Mr. W. R. Ingalls. The famous author of 'Ore Dressing' received an attentive hearing to his timely description of tests made by him in the concentration of the silver ores of Cobalt. The editor of the *Engineering and Mining Journal* gave an excellent paper on recent progress in electric zinc smelting, a subject on which he is a recognized authority. So far there had been but little discussion; in the afternoon, however, the paper on the domes of Nova Scotia, by myself, put several of the representatives of the maritime Province on the alert. It was known that in 1905 I had made a report for the Government on the best method of aiding the Nova Scotian gold-mining industry, and it was known that the report had not been published, because it was not optimistic. The beautiful structure of the doubly anticlinal lodes of this region and the attempt to explain the mysterious crenulation characteristic of the veins was subordinated to the personal and political aspects of the subject. However, my desire to be fair and to be as discreet as circumstances permitted was fortunately appreciated and elicited the most friendly comment from Messrs. John E. Hardman and F. H. Sexton, both of whom made notable contributions to the ensuing discussion. Papers on the geology of Porepine were then presented by Messrs. A. E. Barlow and Reginald E. Hore. These received close attention, and the comment of Messrs. J. B. Tyrrell and W. F. Ferrier. Then came an unexpected outburst on the part of Mr. H. E. T. Haultain, professor of mining in Toronto University. He complained that certain geologists took themselves too seriously and so forth. This provoked no retort, despite the fact that the

president invited the culprits to respond. Good nature marked all the proceedings and prevented friction throughout. Mr. Charles A. O'Connell gave the story of Cobalt and foretold the extent of its probable productivity. His recital of facts was interesting and his forecast seemed to me to be reasonable. Incidentally, to those of us who had not been to Cobalt he gave an instructive outline of the ore occurrence in that area. Mr. Tyrrell submitted the data collected by him in regard to the Coppermine district, an almost mythical part of the Northland. He has traveled widely throughout sub-Arctic Canada, a part of the earth's surface that has been as yet but slightly explored and offers many chances to the mining adventurer. During this session the president announced that Capt. Scott had reached the South Pole, evoking general (but mistaken) applause, for we learned next day that Capt. Roald Amundsen was the man who had accomplished the feat. He also is the man who deserved whatever honor it may carry, for he found the northwest passage, the chief result of the long continued gymnastic exercise and misplaced sentiment associated with polar adventure. If 5-ounce gold were announced at either Pole, or near either of them, I venture to say that there are a hundred prospectors in Canada and Alaska that would get there, without fuss, medals, or speeches. In the evening of this, the second day, we had a smoking concert, rendered memorable by one of Mr. James F. Kemp's humorous sketches. This time it was an account, illustrated by the magic lantern, of how he reached the Pole and what he found there. Colonel A. M. Hay sang a clever composition of his own on a kindred subject; Mr. J. Parke Channing told some excellent stories; I ventured, under the protection of the chairman, Mr. J. J. Penhale, a fellow Cornishman, to read some supposedly humorous verses; and the harmony of the proceedings was emphasized by a glee club from the University, together with general singing, such, for example, as the chorus following the rendering by Mr. R. W. Brock, the director of the Canadian Geological Survey, of 'Drill, ye farriers, drill', the official saga of the Canadian Mining Institute.

The last morning session was devoted to several important papers. Mr. J. Parke Channing gave a lucid and instructive description of the mining and milling methods practised at the Miami copper mine. The ore averages 2.58 per cent copper, disseminated in schist as chalcocite. Of this, 75 per cent is extracted, so that the yield is 37 pounds copper per ton of ore. Among the noteworthy features is the saving of water, only 365 to 500 gallons of new water being consumed per ton of ore treated in the concentrator. The total consumption of new and re-used water is 2100 American gallons per ton of ore. Reference was made to the good work done by the Hardinge conical tube-mills, a mention highly pleasing to the inventor, who was present in the audience. Power at Miami costs 1.25 cents per kilowatt-hour, oil being used at \$1.70 per barrel delivered. In response to a question, Mr. Channing outlined the story of the discovery of this famous mine, and showed how sometimes romance is linked to science. This was a pleasant touch. Then came another unexpected incident, Mr. Haultain drawing attention to the fact that two such authorities as Messrs. Richards and Channing had adopted the style of using the singular of tailing, concentrate, slime, sand, and similar terms, when the meaning does not involve a plural idea. Mr. Haultain congratulated the reformer to whom this usage was to be credited, but asserted his own undeviating conservatism in the matter. After Mr. Channing came Mr. F. Lynwood Garrison with a paper on the persistence of ore in depth. The subject, of course, is highly contentious but always fascinating. The discussion was started by a recognized authority, the

Columbia University professor, Mr. Kemp, and was continued by several other experienced men. This discussion, when it appears in print, will prove interesting. A thoughtful paper on the education of miners was presented by Mr. F. H. Sexton, who is known to have done excellent educational work in Nova Scotia. The paper was based on his experience in that Province, supplemented by the careful study of European methods. The professor of mining at McGill University, Mr. J. B. Porter, offered some useful comment, and others followed. It was evident then, as at other times during the meeting, that those assembled were as quick to appreciate careful scientific study as they were to detect slipshod reasoning or merely showy observations. It must be added, however, that there was not much of the meretricious type of exposition. The papers were mainly earnest contributions to technology. In the afternoon two famous geologists, Messrs. James F. Kemp and Waldemar Lindgren, addressed the convention on favorite subjects, namely, contact zones and vein formation. Mr. Kemp supplemented his researches on the garnets and other minerals that testify to the agency of magmatic waters at the contact of eruptive rocks with limestone, as illustrated by andradite, a ferruginous garnet. Mr. Lindgren described the detailed structure of the veins at Republic, in the state of Washington, and drew attention to the replacement of calcite by quartz; also the frequent presence (in veins of geologically recent age) of adularia, a variety of orthoclase. I had heard him lecture at McGill University, Montreal, a few days previous, and regretted that others present had not been so fortunate. In the evening a public banquet marked the close of the meeting. This concluding function was likewise highly successful. The result of the election for a new president was announced most gracefully by the unsuccessful competitor, Mr. G. G. S. Lindsey, K. C., a public-spirited citizen of Toronto, who honored himself in his generous tribute to Mr. A. E. Barlow, elected president that day. A society is fortunate that has the choice of two such men. Mr. Barlow, I ascertained later, is beloved throughout the northern mining regions of Canada, as much for his geological ability as for his manly sincerity. The toast of the Ontario legislature received response from Capt. H. A. C. Machin, who used his fine voice, not only in an effective speech but in song as well, later in the proceedings. The Mining Industry was the toast to which Mr. Channing responded; it is not often that engineers are good speakers, but this was the second time the same day that my friend had proved an exception. Responses to the toast of the Sister Societies were made by Messrs. Kemp, Sexton, and myself. This suggests the mention of the fact that the American Institute sent a delegation of thoroughly representative men, many of whom might be rated as also representing the Mining and Metallurgical Society of America. The British Institution was not officially represented by anyone, for I was there unofficially. This was a great pity, for at one time it had been planned to hold a joint meeting of the Institution and the Canadian Institute. All I need to say is that my compatriots missed a rare chance to become acquainted with men and things worth knowing. The meeting, in my opinion, was one of the most pleasant and instructive ever held. It was marked by the hospitality of the Canadians and the valuable papers of the American contingent. For the excellent arrangements all of us were in debt to Mr. H. Mortimer-Lamb, the secretary. This, I am glad to add, was generally recognized. The Canadian Institute seems destined to be a common meeting-place for those that search for minerals and describe their experience in the language if not always of the Bible, nor even of Shakespeare, then at least in a tongue that passes current throughout the chief mining regions of the world.

The Future of Cobalt

By CHARLES A. O'CONNELL

*Having resided in Cobalt for the past seven years, I am more of an optimist than the majority of engineers, but the longer I live there the more I am convinced that this district is without a peer on the continent. The proved ore-bearing zone is a rectangle five by three miles, and from within this zone there has been produced in seven years to January 1, 1912, 126,064,189 oz. of silver. I do not think there has ever been anywhere on the continent a district as rich as Cobalt, which was so long producing before it attracted particular notice. It was not until August 1906, three years after the discovery, that

concentrate. It is difficult to state the exact amount of dividends paid, but the records show that \$31,671,622 was distributed by companies making returns to the Department of Mines. To this should be added at least \$2,000,000 as the profits from privately owned properties. From the inception of operation in the year 1904 to date 47 separate mines have shipped to the smelters, but 17 of this number did not contribute to the output during 1911.

Much has been said and written as to the geology of the Cobalt area, and the articles by W. G. Miller, Cyril Knight, and others have been especially important. The bulk of the ore, as formerly, comes from the Lower Huronian formation, and while the amount contributed from the Keewatin series has been considerable, it forms only a portion of the whole. The quantity of ore extracted from the veins in the diabase is small. Since the year 1906 the extent of the proved ore-bearing zone has not been enlarged. The limit is marked on the south and east by the Temiskaming mine, on the west by the Princess, and on the north by the Hudson Bay. The district west of the town of Cobalt, extending to Portage bay, has been prospected, but no productive veins have as yet been found. The properties on what is termed the 'West Ridge', extending from the Hudson Bay on the north to the Buffalo on the south, have been especially consistent producers. This is largely accounted for by the multiplicity of veins in the Huronian formation along this ridge. Taking a line from the Hudson Bay through the Trethewey, Comiagas, and Buffalo mines, I would venture to say that in this area there are more than 80 known productive veins. These are largely made up of the main vein systems running east and west from which innumerable branches lead. The Trethewey property alone, from the main vein system near the south end of the property, has 22 productive veins. Some of these are branches from the main vein system, which strikes east. It will doubtless interest all mining engineers and geologists to know that only four of these veins showed a marked outcrop on the surface, and ore was found in only two at the surface. More than six do not come closer to the surface than 50 feet.

As to the origin of the ore, much has been said and written during the past eight years, and many theories have been advanced. Personally I am firmly convinced that the theory first advanced by W. G. Miller is the only one tenable.

During the past three years much has appeared in the public press as to the decline of the Cobalt, but I am extremely doubtful whether the peak of production has yet been reached. The immense quantity of milling ore which is to be extracted leads to the belief that the maximum number of tons per annum will not be reached for several years. The Nipissing Mines Co. is now constructing a mill with a capacity of 200 tons per day, and this will be in operation some time in the fall. This will largely increase the output of the district, as it is admitted by all that this property (the Nipissing) is still the premier producer. On this property, comprising 846 acres, has been found the greatest number of veins, and the tonnage of milling ore will undoubtedly be much larger than that contained in any of the other mines at Cobalt. There has been a vast improvement in the method of concentration during the past five years, and the tonnage in all the mills has been largely increased.

The history of most mining districts of a similar nature shows that the time from the inception of operation to the peak of production does not cover more than seven or eight years. The decline to nominal production covers a much longer period, and when it is known that there are extremely favorable chances of finding other productive orebodies within the proved ore zone it will be seen that ten years would not be too long a period to estimate as the future minimum life of Cobalt. I am willing to predict that the total production will exceed 250,000,000 oz., and while this statement may be criticized as being the view of an extreme optimist, I make it without reserve, for it is largely based on the figures covering the past seven years' production as herein given.

MAP OF THE COBALT DISTRICT.

more than passing notice was given the district. At that time there were about twelve producing properties. The whole of the township of Coleman had been staked, and any man who could show 'cobalt bloom' on his claim could sell it. Some have said there was an orgy of speculation, but that was largely fabrication. I know well that all the statements issued by the Department of Mines, and most of those over the signature of W. G. Miller, warned the public time and time again against reckless speculation and the purchase of claims that were not inside the proved ore-bearing zone or that had not been examined by a competent mining engineer. Mr. Cochrane and the officers of the Department did all in their power to protect the public.

The production to date is stated as being 126,064,189 oz. fine silver, worth \$64,918,752. The first shipments were made in 1904. The total shipped that year was 159 tons. The following year the shipments amounted to over 2300 tons, and from then increased by leaps and bounds until the year 1910, when 33,000 tons was shipped. The shipment in that year had a value of \$15,500,000. In 1911 the tonnage declined somewhat and less than 25,000 tons was shipped, but the grade was higher, owing to the fact that more was shipped in the form of bullion and con-

*Abstract of a paper read before the Canadian Mining Institute.

Packing Supplies in a Mining Region

By JAMES DAVIS

Many undeveloped prospects, that are miles away from a railroad, and by no means accessible with wagons, remain undeveloped for no other reason than that they are too hard to reach with suitable machinery. From a purely economic standpoint, the miner who goes into mining to win, necessarily must ask the question: "Is it accessible? Can this prospect be reached with supplies without too much expense; without enhancing the cost of the venture beyond hope of profit?"

This problem can be met, to a certain degree, by the proficient packer. In many instances an unskilled muleteer is employed to transport heavy pieces of machinery and supplies, to the detriment of the enterprise, owing to

'racked' saddles are likely to cause injury to the animal, and should be avoided. The saddle should always be built to fit the animal's back, therefore 1 and 2 of Fig. I should be hewn, and smoothed accordingly. Incidental to the frame are the breast-strap and crupper. These are fastened to the frame by means of buckles, which can be used to regulate the position of the frame upon the back.

The pad and cover may be taken together as the second part of the saddle. The pad is made of canvas and leather, and takes the form of a rectangular bag with holes cut in the plane across the centre, large enough to accommodate the horns of the frame. Both sides of this bag are filled with grass of some sort, so that the rough sur-

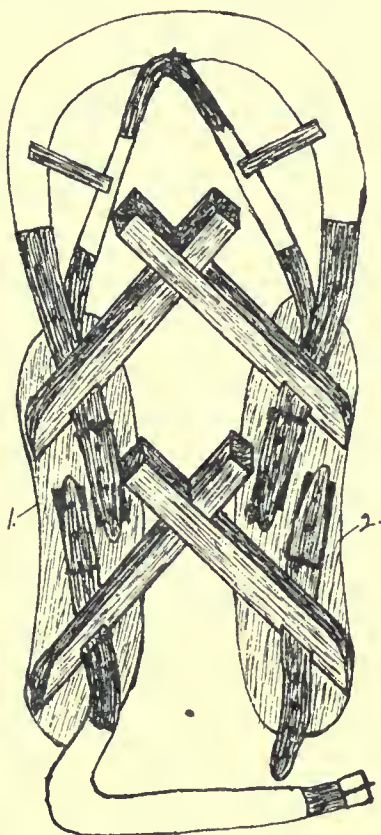

FIG. I. THE SADDLE.

the cost such a course involves, not only in regard to unnecessary labor, but also in the maiming and often complete incapacitating of animals. In this article I aim to remind those who are confronted with such difficulties that there is a comparatively easy and scientific way to transport certain loads; that there exist certain 'tricks of the trade', certain hitches and devices in packing, that call for attention on the part of the adventurer. The following illustrations will, I hope, give some idea of the use of the most important hitches, and frames, used by experienced packers, which I have seen employed with success in northern California by such skilled men as B. J. Neilon and Herbert Finley, who have packed machinery in the most rugged section of the state.

THE SADDLE

The modern pack-saddle is composed of two distinct parts; the tree or frame, and the pad and cover. The frame is usually built of seasoned oak timber. It has six component parts, as shown in the figure, which are fastened together with bolts suitable to the size of the frame. In many instances nails are used for fastening, but they are far inferior to bolts, as there is apt to be some 'give' to nails when they are not clinched. Such

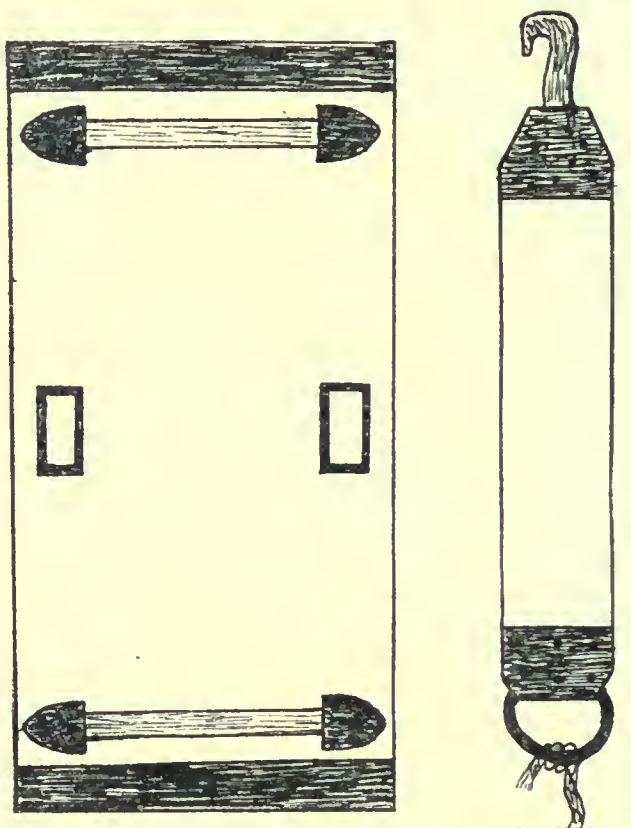

FIG. II. COVER AND CINCH.

face of the pack may rest upon this soft pillow. The cover is nothing more than a canvas strip which is thrown over the saddle-pad to bear the brunt of wear and tear. It fits on the saddle exactly like the pad, and is in fact a part of it.

ROPES

Pack ropes may be divided into three classes, of which the cargo ropes are the first class. These are usually half-inch ropes about 35 or 40 ft. long, with a noose at one end. The cargo rope is used to lash or bind several packages into side-pack, which in turn is half a mule-load. It is much more convenient to handle a tightly lashed side-pack consisting of several different parts than to handle the same parts separately. As a rule, there are two cargo ropes per animal, in a well regulated outfit, as provision must be made for two lashed side-packs.

The sling ropes are the second class. These ropes are also about 35 or 40 ft. long, and are frequently interchanged with ropes of the first class. In fact, most pack ropes are of this average length. At each end of this rope there is a 'turks-head' knot. The sling rope is fastened on the fore horns of the saddle by means of a double half-hitch at the centre. The primary purpose for

which this rope is used is to hold the side-packs in position in order to strike a balance.

The last and most important class embraces the lash ropes. Rope, cinch, and hook comprise the lash-rope. The cinch is generally made of heavy canvas, while the rope is $\frac{3}{4}$ or $\frac{7}{8}$ in. and about 40 ft. long; the hook may be

packers. Fig. IV shows a view of a diamond hitch from the top.

THE COMMON LOAD

The common load, as I have chosen to call it, is usually made up of two side-packs. I shall not exclude from this load the incidental top-pack, for very often packages

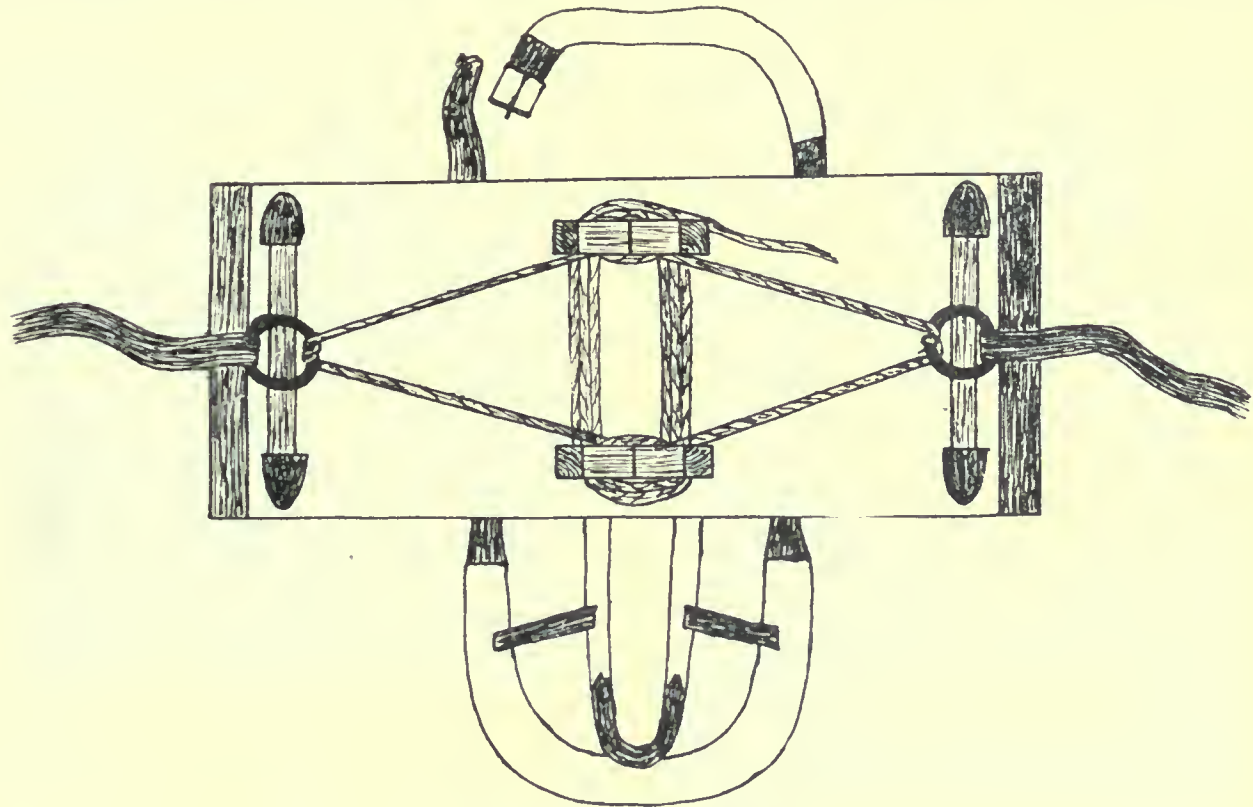

FIG. III. THE PACK-SADDLE.

made from any hard, tough wood, oak being very serviceable.

THE DIAMOND HITCH

It is with the lash-rope that the well known diamond hitch is formed. Too much cannot be said in favor of this simple, effective, systematized device. As soon as the packer determines that the load is riding straight by

of small weight deserve special care, and therefore cannot be lashed to other portions of the burden. In this case such a top-pack may be placed on top of the two side-packs, directly above the horns of the saddle, assuming that the side-packs are of equal weight. However, a top-pack of this type can be made an effective instrument in balancing an uneven load. In that case, the lesser side-

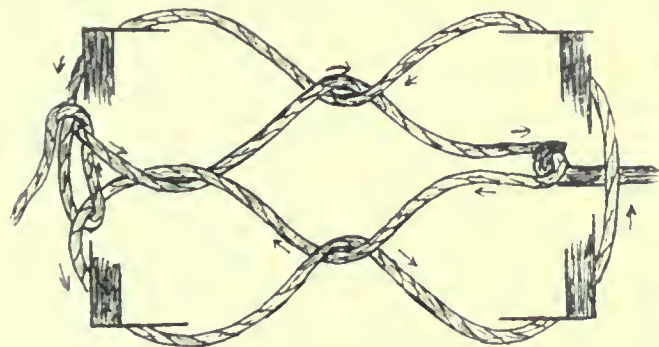

FIG. IV. THE DIAMOND HITCH.

sighting along the line of the horns of the saddle and the animal's back as it is being led away at its regular pace, he completes his work with the diamond hitch. There are various other hitches, as the 'double diamond', and the 'squaw hitch', but of all hitches the diamond is far superior, except in a few special cases. The double diamond is frequently used with high top-packs, and the squaw hitch is often the choice of those who work alone, but even in such instances the diamond is preferred by men who know the relative merits of the two. The figure illustrates the diamond hitch better than a detailed description, while skill in the art of 'throwing' the diamond, as distinct from 'weaving' it, can only be attained with satisfaction by actual experience and instruction by proficient

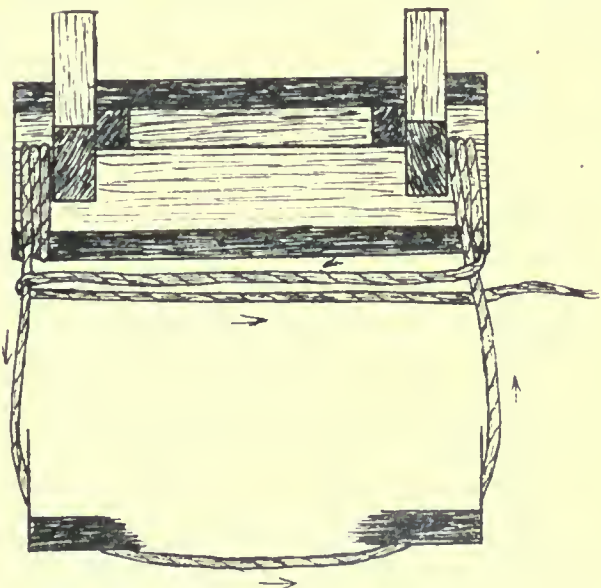

FIG. V. TOP-PACK FRAME.

pack is lowered slightly and the top pack placed on top of it rather than on the horns, as mentioned before. It is always best to place the top-pack beneath the tie-ends of the sling rope, which crosses over the pack. Frequently, however, the sling rope is tied and the top-pack placed

over it, but the first method is preferable where possible.

WEIGHT AGAINST BULK

Inexperienced men have often called my attention to a 'crooked' load while on the trail. Such loads are generally not crooked except to the passerby. Among muleteers who know the business there exists what might be called the rule of 'bulk against weight.' A bulky box weighing 100 lb. can often be placed to offset a side-pack of smaller proportions weighing 150 lb. Such a load appears awkward and uncomfortable on the beast, but so long as the saddle sets straight the packer rests assured that no discomfort is produced. The essential thing, then, is to strike a balance with the load, and to always keep the saddle in position, and in proper relation to the burden and the saddle blankets.

THE BARREL AND PIPE HITCH

Freight in various forms and shapes is constantly confronting the muleteer with as many different problems. Barrel loads are a source of much chagrin to the inexperienced adventurer, and yet professional packers rejoice

PACKING CABLE FOR THE NELLIE TRAMWAY, TELLURIDE.

when barrels of sugar, pork, and particularly whisky, must be transported many miles. The barrel hitch, a handy device to meet the difficulty, readily transforms the load from an eyesore to a treat. Here again the trick is performed with the sling rope. I have explained above how the sling rope is attached to the saddle. One division of this rope is thrown to the 'off' side of the animal. The 'near' side rope is brought around in such a way that it is wrapped several times around the rear horn, leaving a small loop between the two, which is then permitted to hang suspended on the 'off' side, similar to the first rope. The barrel is then lifted to the top of the saddle, so that it rests on the forks of the horns. The two ropes are gathered up in a coil and thrown over the top of the barrel, so that they pass over the top and bottom hoops respectively, or at least very near them. With the first barrel still resting on the horns, and the two ropes as described, barrel No. 2 may be lifted into position. The rear rope can then be drawn over barrel No. 2 near the band, as in the first case, and carried through the loop between the horns, and thence back over the front band. At this point the first rope, which was described as being beneath the fore part of barrel No. 2, is carried over and tied to the rear rope, which has already been passed through the loop. Having tied these two ropes, the off-side man may roll barrel No. 1, from the top, settling it in position on the off-side. If the load sets too high, or the side packs are unevenly balanced, the trouble may be easily remedied and adjusted by slacking up in the knot.

The same hitch may be used for pipe loads, in fact this hitch is, properly speaking, the 'pipe-hitch,' though it is most frequently called the barrel hitch. When packing long joints of pipe, however, the cargo ropes are used to tie the

ends together to hold the loads in place, as well as to prevent any overhanging tree branches from catching hold between the two side packs.

THE TOP PACK

Large unwieldy top-packs cause more trouble than any other load, both to animal and muleteer. They are constantly shifting from balance, and a very slight movement may plunge an animal to destruction. In order to accommodate single packs which are too heavy for side packs, the top-pack frame was devised. This construction is nothing more than a heavy, false frame built of 2 by 4-in. scantling and made to fit solidly on the saddle. The two pieces on the side are notched on top at each end, and into this incision is carefully fitted the cross-piece that joins the two sides. When fitted upon the saddle these cross-pieces are level on top, any slipping either to the front or to the rear is prevented by the horns of the saddle as these are adjacent to the cross-pieces, respectively, and between them. The principal knack in using a top-pack frame lies in tying it firmly into position. On every frame there is usually about three inches of the longitudinal scantling (as distinct from the cross-pieces) that extends beyond the cross-pieces of the frame. Beginning again at the point of origin of the sling rope, which is at the front horn of the saddle, the two divisions of the rope are used to fasten the frame on both sides of the saddle. On the near-side the rope is drawn free and is then carried over the jutting scantling, given about three turns completely around, thence it is carried down around beneath the saddle corner, over the cinch, around the rear corner, up again, and over the jutting point at the rear end of the frame; about three turns are taken as at the front end and then the rope is tightened and tied as shown in the figure. The same operation is performed on the off-side, and when well done and completed the frame is fixed and immovable. The top of the cross-pieces then affords a level plane which will accommodate any angular load. On a top-pack no hitch with a sling is necessary. The load is merely balanced, adjusted, and, if it is a piece of machinery or the like, may often be prevented from slipping by the use of nails which can be driven into the frame. The diamond hitch with the lash-rope is really all that is needed. Very often where the trail to be followed is very much down-hill, or up-hill, the front cross-piece can be built up a trifle higher than the rear, or the reverse, according to the grade of the trail which the pack must be carried. Fig. V shows the top-pack frame fitted to the saddle and tied with the sling rope.

THE LUMBER FRAME

One of the most useful contrivances of the muleteer is the lumber frame. Lumber being a necessary article must often be carried miles on mule-back, and as it is unwieldy and cumbersome it is often more expensive to transport it by pack-train than to whip-saw it. In fact it would be almost invariably so, if the inventive mind of the packer had not quickly devised an easy way of loading lumber. The lumber frame is easily described, because of its simplicity. It is built up of two divisions which are similar in structure. Each division is made of 1 by 12 by 36-in. lumber. Across each end of this piece is nailed a strip to strengthen the board, and at the same time to accommodate pegs which are driven into holes near the lower ends of the strips. The lumber rests upon these pegs, is balanced, and lashed by the lash-rope. The sling rope is used to tie the ends together. The two divisions are tied together with $\frac{1}{4}$ or $\frac{3}{8}$ -in. rope, and in order to make them firm the two tie-ropes are in turn tied together with a third rope which can be twisted by means of a short stick, held in place by a string.

PACKING A MULLER RING

It seems that there is always a solution for every problem. For a long time a muller ring, if packed over a very rough trail meant much risk, owing to its shape and weight. A ring weighing 450 lb. and of awkward shape naturally falls into the class of hard top-packs. But after packing these rings on top for many years the idea of placing the rings around the mule occurred to one of the packers. The ques-

tion of how to get the mule into the ring arose, but met with ready solution, as it was of sufficient diameter to lift over the mule's rump, consequently it is no more than a matter of placing the ring on the ground, and leading the mule over it so that its hind feet will be within the circle. Here the top-pack frame comes into use again, as the pack must be elevated so that the lower portion will not interfere with

the mule's stride nor strike the ground when inequalities in the trail must be crossed. Another ideal pack presents itself in transporting a long wire cable. It is practicable in such cases to wind the cable into coils, making the regular load of two side-packs on every mule, and having these coils as numerous as the length of the cable requires, linking them together by lengths that will fit the trail turns best.

PACKING A MULLER RING.

THE TOP PACK.

The Purisima Grande Mill, Pachuca

By E. GIRAULT

*This mill, designed and built under my supervision, is at the place once occupied by the oldest *hacienda de patio* of Pachuca, where it is said that Bartholomé de Medina invented in 1557 the amalgamation process. Some interesting features of the new mill are that it is built on practically level ground and that Chilean mills are used as primary grinding machines; four of these were taken from the old mill. These four Chilean mills are the only old machinery used in the new construction. About 100 tons of ore is put through the mill per 24 hours; the general plan of operation consists of fine grinding, concentrating, agitation in Pachuca tanks, filtration with Moore filters, and precipitation on zinc-shavings.

Ore Treated.—The ores are from the Guadalupe and Fresnillo mines; ore coming from the lower levels contains an average of 75% silica, 10% lime, and 7% iron. The ore from the upper levels carries oxides of manganese and iron; and although it proved refractory in the old patio process, it causes no trouble in cyaniding.

Grinding.—There are one 15 by 9-in. Blake crusher, and five Krupp Chilean mills with runners of 1.5-metre diameter, weighing with new tires 4080 kg. each. The runner shafts can move up and down independently, by which arrangement the wear of the tires and dies is uniform. The five Chilean mills are driven by a 100-hp. motor and have a speed of 18 r.p.m.; the power consumption of each mill varies from 15 to 20 hp., depending on the hardness of the ore and the proportion of fine and coarse.

The consistence of the pulp in the mills is 1 of solid to 6 or 7 parts of solution of 0.2% cyanide. Nine kilograms of lime is added per ton of ore. The mills are provided with No. 4 screens, the discharge is 10 cm. above the bottom, and the depth of the pulp is 20 centimetres.

*Abstract from the *Informes y Memorias del Instituto Mexicano de Minas y Metalurgia* by G. Witteveen

The average capacity per mill per day is 24 tons when the feed consists of 78% fine and 22% coarse, calling fine that which does not exceed 5 cm. Recent sizing tests of the discharged pulp showed:

	Percent.
On 100-mesh	38.2
On 150-mesh	9.5
On 200-mesh	5.1
Through 200-mesh	47.2

The tires and dies are of manganese steel. The tires, when new, weigh 1660 kg.; they last six months, and at the time of renewal weigh 400 kg. The dies weigh 1500 kg.; they last three months and when worn down to 300 kg. are renewed. The consumption of iron is 830 gm. per ton crushed, which is three or four times as much as in stamp-mills. Taking into account the total iron and steel consumed, it amounts to 1.054 kg. per ton of ore crushed.

Concentration.—The discharge from each mill goes over one Willey table. The extraction on these tables is about 18% of the content in 1/2% of the weight of the ore. At the same time part of the classification of the pulp takes place on the tables, some slime being sent directly to the thickeners.

Classifiers. There are two Dorr classifiers.

Tube-Mills.—Of the two No. 5 Krupp tube-mills, 1200 by 6000 mm., only one is in operation at this time. They are provided with El Oro linings, cast in Pachuca with 25% manganese steel from old tires and dies. These linings weigh 6 to 7 tons and last more than a year; the price is \$0.12 per kg. Instead of flint, hard 10-cm. pieces of rock from the mine, selected from the dump, are used. The daily consumption is about 1500 kg. The tube-mill discharge is pumped up about 11 ft. to the Dorr classifiers by means of a 10 by 54-in. Premier pump.

Centrifugal Slime Pumps. The slime is pumped 20.5

metres to the thickener by means of No. 2 Traylor centrifugal sand-pumps. Each pump has a capacity of over 100 tons of slime per day, the slime having a consistence of 1 of solid to 7.7 of solution. Each pump is driven by a 20-hp. motor and consumes 16.3 hp. They are fed under pressure through a conical receiver of 6 ft. diameter. The pumps have been in operation almost one year without causing the slightest trouble. The Traylor pumps make 1700 r.p.m. and can lift slime of 1 to 4 solution to a height of 20.5 m. The mechanical efficiency by actual measurement is 18.4%. The linings are cast in Pachuca; they are set with cement and last two weeks. The shafts last three months, the packing three weeks. With the exception of the high power consumption the pumps are satisfactory.

Thickener.—One 30 by 12-ft. Dorr thickener handles easily more than 100 tons of the thickening pulp from 1:7.7 to 1:1.44. A sizing test of the discharged pulp showed:

	Per cent.
On 100-mesh	12.27
On 150-mesh	8.50
On 200-mesh	3.95
Through 200-mesh	75.28

Pachuca Tanks.—There are four 15 by 45-ft. Pachuca tanks, which are charged with 94 tons of slime and 136 of solution, of about 0.257% KCN. It takes a little less than 24 hr. to fill a tank. During the filling a moderate agitation is maintained. After the tank is full, agitation by means of the air-lift is kept up for 36 hr., using air at 25 lb. pressure. The tank is then left to settle for about four hours. A series of comparative tests showed not only that lead acetate is not necessary, but that the extraction was not as good and the cyanide consumption higher when using acetate. With acetate the cyanide consumption was 676 gm. per ton and the extraction 73.40%, against 524 gm. per ton and 74.7% without it. These results coincide with those obtained in other small mills in Pachuca, but not with San Rafael practice, where a constant use of acetate is necessary to get a good extraction. The reason for this difference seems to be that in the small mills, all the solution is passed through the zinc-boxes, which is not possible in San Rafael, owing to the large quantity of solution in circulation.

Compressor.—The 300-cu. ft. compressor for agitation, filtration, and other purposes, has in some cases proved to be insufficient. The pressure of the air is 25 lb. Two tanks in active agitation consume 26.3 hp.; two tanks and the filter, 31 hp., which is also sufficient to keep the four tanks in moderate agitation. In the plans, the air consumption per tank was estimated at 100 cu. ft. per minute with a power consumption of 10 horse-power.

Filter Plant.—A Moore filter with two sets of twenty 10 by 6-ft. leaves is used. The contents of a Pachuca tank containing 95 tons of dry slime is filtered as follows: New filter-leaves, 20 cycles in 12 hr. with 1 to 1¼-in. cake; half-worn leaves, 23 cycles in 14 hr. with ¾ to 7/8-in. cake; old leaves, 30 cycles in 20 hr. with ½-in. cake. Taking the average of 62 tanks, the unwashed cake contained 50 gm. of silver per ton and the washed cake 49 gm. The water of the discharged cake has 2.5 gm. silver per ton.

Precipitation is effected in five zinc-boxes of five 3 by 3 by 2-ft. 9-in. compartments. No. 9 zinc is cut into shavings 0.15 mm. thick. The zinc consumption is 1.450 kg. of precipitated silver.

Melting.—There are four coke furnaces, 2 ft. 2 in. inside diameter and 4 ft. high, with 2-ft. sheet-iron chimneys 80 ft. high. Either No. 300 Dixon graphite crucibles or Morgan crucibles with clay lining are used. The precipitate, air dried in the Shriver press, contains 8 to 14% moisture and is melted with the following fluxes:

	Kg.
Moist precipitate	100
Ground glass	10
Ground borax	6
Carbonate of soda	8

The first melt lasts about 6 hr., the next one 4 hr. The total cost of the mill, including what has been adapted from the old mill, has been about ₱1500 per ton per day capacity. The total power consumption is 2.07 hp. per ton of ore. From the results obtained in this mill, it seems that with a small mill the installation cost of the combination slow-speed Chilean mills and tube-mills is less, and that the operating cost and the extraction are about the same as with stamp-mills.

Philippine Bureau of Mines

The Division of Mines has had four men in the field for the past two months, investigating the iron deposits of Bulacan province. Recent development work has shown that a much greater deposit exists than formerly was thought to be the case. The special work that the Division of Mines party is undertaking is the magnetic survey of the whole field, and investigation of adjacent water-power sites. It is very gratifying to report that Wilson & Rose, of Cavite, have completed plans for an improved eupola furnace and up-to-date machinery for making plough points and shares to be operated in this field. They expect to have their new plant in operation in about six months. There are now five native furnaces running in the district.

Three large companies are making serious preparation for the construction of cement mills in the Philippine Islands. One of these will be on Laguna de Bay, not far from Manila, and the other two probably on the island of Cebu. It is understood that machinery for one of these plants has already been ordered.

The Division of Mines has recently moved into commodious quarters on the ground floor of the new wing in the Bureau of Science in Manila. There is now space for a museum and laboratories, making this probably the largest geological and mining headquarters in the Far East. The work of this division has recently been extended beyond the confines of the Philippine Islands, assaying and cyanide tests having been made on samples from the Celebes, Indo-China, Mongolia, and neighboring localities.

The staff has been increased so that in addition to the chief of the division, who is chief geologist, there is one mining engineer whose specialty is gold and copper, an assayer who has had special training, a coal engineer, a geologist who has had special training in the geology of non-metallie minerals, and assistant geologist with special training in petrography, and two Filipino assistants who have studied in engineering schools in the United States and Europe. Also, the Division of Mines coöperates with the geological department of the University in special research work. For the fourth annual carnival, which took place between February 3 and 10, 1912, a large exhibit has been prepared in which the Division of Mines and the various mining men over the Islands are coöperating. It is expected that within another year the equipment of the Division of Mines will be augmented by the installation of a complete ore-testing laboratory. A lack of funds has delayed this very much needed feature.

On the whole, the Philippine mining industry is in far better condition than at any time in the past, as the unscrupulous promoter has been pretty generally weeded out of the mining element, and the ridiculous prospectuses of the early days have been replaced by more conservative promotion literature. It is almost a certainty that the present mining laws, which have seriously hampered development, will be materially changed in the near future. The labor situation seems to be improving in some quarters at least, and the main thing needed now is capital, with experienced men to properly invest it. The outlook is, on the whole, distinctly encouraging.

THE Waihi Grand Junction Co. in 1911 produced bullion to the value of £142,604, an increase of £9081 as compared with 1910. The total value of bullion produced by the mine is £544,714.

Gold Mining in Formosa

By W. M. KNOX

Formosa, or Tai-wan, as it is called in the vernacular, is a large island lying ninety miles off the southeast coast of China, and extends from 25°19' to 21°54'N. and from 121°15' to 122°05'E. It is shaped like an ellipse, with its longer axis north and south, corresponding with a chain of mountains, the Ta-shan, which has lofty peaks, one of which is said to reach 12,850 ft. This range divides the island into a broad western versant with alluvial plants, and a narrow eastern versant ending in a precipitous coast line. The western portion was, at the advent of the Portuguese in the sixteenth century, occupied by Chinese, while the rougher central and eastern parts were given over to savage natives. Owing to the hostility of the native tribes, the notorious head-hunters of Formosa, the interior of the island has been very little explored and is practically inaccessible. This being the case little is known of the geology of the mineral deposits and natural resources of this area. At the close of the Chino-Japanese war the island was transferred to Japan, and its administration is now in the hands of that country. Gold, silver, copper, coal, sulphur, and petroleum are the principal sources of mineral wealth. The production of these during the past five years is shown in the table below:

possible for the following reasons: (1) the ground is too low grade, being less than 5c. per cu. yd.; (2) the bedrock upon which most of the gold is found is too hard to be cut by the buckets of a dredge, and consequently bedrock gold cannot be recovered; (3) the area is too limited to warrant a dredge, besides the claims are scattered and not adjoining; (4) the nests of hard limestone boulders would soon destroy a dredge.

The method of mining at present employed, that of tribute by Chinese, is in my estimation the only one suitable for this district. Hydraulic mining is not adapted to work here, owing to the flatness of the country and the impossibility of disposing of the large amount of tailing made by that form of mining. A hydraulic giant would soon block up the harbor of Keelung, and for this reason would never be permitted by the Japanese governmental authorities to be put into operation.

This is the most important placer district of the island. Two other small districts are known at the mouths of rivers flowing toward the east coast. Years ago natives prevented work on these and nothing has been done since. The fact that they are not now being worked is good evidence of their not being rich.

MINERAL PRODUCTION OF FORMOSA, 1906-1910.

* 1 tsubo = 3.95 sq. yd. = 1/1210 acres.												
1 yen = 49.8c.												
1 sen = 1/100 yen.												

The gold deposits are in the northern part of the island, and consist of both placers and veins. The main alluvial deposits are found flanking the Keelung river, a stream about 30 ft. wide, with a fairly steep gradient. The ground now being worked is that on the benches bordering on both sides of the river. The river bed is too low grade, and the water too troublesome to handle. Claims have been taken up for a distance of about twelve miles along the river bank, but not all this area is covered by mining rights, there being sandy places and barren patches intervening. About 1,500,000 sq. tsubo, or 1250 acres, held at present under mining patents, will cover the workable places. During my trip twenty of these claims were visited and carefully tested by panning, and the whole twelve miles of river was traversed and inspected.

On a claim owned by Kimura, consisting of 600 tsubo, 15 Chinese were at work. One day's output by these miners was purchased for 1.65 yen. The gold was weighed, its value calculated, and the yardage treated estimated, and it was thus found that the value of the gravel treated was less than 5c. per cubic yard. Farther down on another claim 30 Chinese were at work, each averaging about 20 sen or 10c. gold per day, treating 1 cu. yd. per man per day, and paying a royalty to the owner. Another claim gave pannings of about 30 sen or 15c. per cubic yard, but this ground has been almost all worked out. There are in all about 300 Chinese at work in this district, all working on the tribute system. The method of working consists of sorting the fine gravel by hand into small baskets, carrying it and dumping it into small sluices.

The gravel is, on an average, 9 to 20 ft. deep, overlain by a stratum of soil 6 to 10 ft. thick. It varies in size from fine pebbles to huge limestone boulders weighing tons. The bedrock is hard slate and flat-lying shales.

As a dredging venture I regard this district as hopeless, the conditions here making that form of mining im-

The sole district where profitable gold-bearing veins are known to exist is in a small range of hills in the north-eastern part of the island, close to the sea. Here an intrusion of andesite in limestone, about 1½ miles in diameter, contains two parallel veins of auriferous quartz, 2 to 20 ft. wide. These fissures are confined to the andesite, outside of which they do not extend.

The Zuiho gold mine, owned by Fujita & Co., is situated on the coast about ten miles southeast of Keelung and one-fourth mile from the shore. There is excellent tide-water transportation; a wire-rope tramway about 6000 ft. long handles ore from mine to mill, working 100 tons per day of about 27 yen ore, which costs 12 yen to mine and mill. The equipment consists of 6 Huntington mills, 8 filter-presses, 18 cyanide tanks, settling-vats, and other machinery. The gold content of the tailing is 2.76 yen. The country rock here is slate and limestone and the gold occurs in two parallel veins, 2 to 20 ft. wide, averaging 6 ft. Nearly 1000 men are employed. Surface men are paid 38 sen per day; 80 sen to miners. The property contains 2,451,360 tsubo and produces about 80,000 yen per month.

The Kinkwaseki gold mine owned by Tanaka & Co., is a little to the north, adjoining the Zuiho mine on the same vein. It is fully equipped, having about 20 stamps, 6 Huntington mills, and works 80 tons per day of 50-yen ore. The cost is 9 yen per ton for mining and 5 yen for milling. This mine produces 100,000 yen per month, and comprises 2,198,400 tsubo.

The Botanko mine, adjoining both these mines, is owned by Kimura & Co. It has 36 stamps, 2 Huntington mills, and full cyanide equipment; it works about 33 tons of 40-yen ore. The cost is 15 yen per ton for working and the output is 150,000 yen per month at a cost of 80,000 yen. This mine consists of 566,083 tsubo.

These mines are not for sale, and as their lines unfortunately cover veins there are no extensions. So it is use-

less for others to try to get a foothold in this district. It may be remarked in passing, that the placer gold found in the district previously described has been derived from the weathering and erosion of these veins. It cannot be seriously questioned that these veins are on the watershed of the Keelung river, and they are beyond doubt the source of all the placer gold on this river. Outside of this district, no other quartz mining is being done on the island, and indeed no other veins are known to exist.

As you leave Keelung to go to Teipeh, the coal mines commence to be seen. No better coal is to be found in Japan proper; many of the seams are from 2 to 10 ft. in thickness. Only one coal seam is known in the southern part of the island and but ten working mines are known to exist in the north.

Timber in the Arisen district is in the interior about 55 miles distant from the west centre; about 560 square miles of timber land averaging 28,000,000 ft. per mile. Many of the trees are 14 to 18 ft. diam., and are known as *hinoke*; they resemble Oregon pine.

At a place called 'Sod' on the east coast is a gold mine owned by a Japanese. The owner started to equip this with modern machinery, but was prevented working by natives who had been prevented from doing placer work at Shaikorán.

At Hokudo north of Teipeh is a large extinct volcano in which is one of the largest sulphur mines in Formosa. Ditosan mountain, nearly 4000 ft. high, in the same locality, contains large quantities of sulphur. From Broutsh, where there is a producing oil well operated by Samuels & Co., down the west coast to Hazen, three-quarters of the length of the island, there are over 170 distinct and well defined evidences of petroleum. In many places the natives simply cut the sod, and it is so saturated with oil that it will burn.

Steam-Shovel Work at Chino

During January 1912 the No. 1 Marion model 91 steam-shovel of the Chino Copper Co., equipped with a $3\frac{1}{2}$ -yd. dipper, loaded 101,547 cu. yd. of material in place in 59 shifts. Of this material, 88,172 cu. yd. was rock and 13,375 cu. yd. was earth. The work for the shovel was complicated, as part of the material was waste and part of it was ore, some of the ore having to be sent to the ore-dumps over a haul of 4500 ft., having a total of 225° curvature with adverse grades up to 4.3%; while the other portions of the ore had to be loaded in 50-ton ore-cars for the mill. Out of a possible 590 hours, the shovel was actually loading 505.56 hours, or at the rate of 200.8 cu. yd. per loading-hour. This is thought to be the record for moving material. The conditions were not especially favorable for work during the month. The shovel was served by two trains only, and was somewhat handicapped through having only 12-yd. ears instead of 18-yd. ears. The shovel crews and the train crews, however, took the deepest interest in the work and used their heads to the best advantage to prevent any delays. The actual cost for labor and supplies for this shovel for January was 12.84c. per cubic yard for stripping, and 9.33c. per ton for loading ore.

L. VOGELSTEIN & Co. give the following figures of German consumption of foreign copper during January 1912:

	Tons.
Imports of copper.....	17,872
Exports of copper.....	956
Consumption of copper.....	17,342

as compared with consumption in January 1911 of 12,690 tons. Of this quantity 16,328 tons was imported from the United States.

PLANS are under way for the construction of 16 new nitrate works in northern Chile during 1912, with a monthly capacity of 1,070,000 Spanish quintals of 101.4 lb. each, and giving employment to 6500 men when in full operation.

Liquid Products From Natural Gas

By IRVING C. ALLEN and GEORGE BURRELL

*By fractionating natural gas, either during or after liquefaction, four products can be commercially obtained. Roughly, these four products may be described as follows: (1) The gaseous product, the common natural gas of commerce; (2) the semi-liquid product, known as the new 'wild' product, which should be used only as a liquefied gas and should be held in high-pressure steel containers only; (3) the light liquid product, or light gasoline used for blending with heavy naphthas; and (4) the heavy liquid product, or ordinary high-grade gasoline. The possibility of handling the second product in the way that Pintsch and blau gases are handled, enabling small towns, hotels, and country estates to have the advantage of gas illumination, manifestly opens a new field of comparatively great importance in the natural-gas industry and should add materially to the investments made in it.

The liquefaction of gases by pressure is not a new industry, but only recently has its application to natural gas been recognized as practicable. Until the past two years the general practice followed in the manufacture of liquid natural gas was to make the product by compression of the gas in single-stage compressors operated at a pressure of 150 to 300 lb. per square inch. The one product obtained, so-called 'natural gasoline', was run into a tank and 'weathered.' The weathering consisted in allowing the lighter portions to volatilize spontaneously and escape into the open air until such time as the boiling away of the liquid had practically ceased. Thus the process involved a loss of 25 to 50%, or even more. This loss was an absolute waste, not only of power and of cost of operating the engines and compressors, but of the product itself.

The next step in the industry was to pass the waste gases (of which only the small quantity used for power had been utilized) from the single-stage compressor through a higher-stage compressor, thereby getting a second and more volatile product—a 'wilder' liquid—which was run back into the first and mixed with the first or heavier condensate. This mixture was then again weathered to a safe degree, whereby it lost the greater part of the more volatile product than had been condensed in the second stage. Recently the process has been improved another step, in that the first-stage compressor product is run into one tank and handled as ordinary gasoline; the second compressor product is run into a second tank and handled as lighter gasoline, with which the heavy refinery naphthas can be enriched.

The last-mentioned method of using the second-stage compressor product should receive wide recognition, and a market for the product should develop that would be no mean factor in the industry. Blending in the proportions of, say, one part of the product to four or five parts of the refinery naphthas makes these heavy naphthas more volatile and of greater value as fuel for automobiles; it also greatly increases their general usefulness. The proportions to be used in blending, however, must be determined more definitely by test. The natural gas of this country frequently contains light products that do not condense in the second-stage compressor, and for which it is practicable and necessary to install three, four, and even higher stage compressors. These light products, true gases at ordinary temperatures and pressures, can be compressed and liquefied, but the liquid gases so obtained must be handled as gases and not as oils.

The mistake heretofore made in the 'natural-gas gasoline' industry, as some have recognized, has been the attempt to handle the light gaseous products as oils and not as gases. Until the manufacturers of this lightest third or fourth-stage compressor product recognize its gaseous nature, the absolute necessity for insuring the safety of the public involves certain restrictions in its transportation, and not until it is realized that this extremely volatile liquid should be handled only in strong steel containers capable of withstanding high pressures will it be transported with safety.

*Abstract from Technical Paper No. 16, Bureau of Mines.

Rogue River Gravel Beds

By CLEMENT H. MACE

In the present search for new dredging fields, the gravel deposits along Rogue river, in southern Oregon, should not be overlooked, and merit careful investigation. The Rogue is a clear mountain stream rising in the Cascades and flowing through the valley of Medford and Grants Pass, now famous for its apples. As compared to the physical surroundings of most mining districts, this region is a paradise, especially to one accustomed to desert or high altitude mining camps. The hills are covered with pine, fir, maple, oak, manzanita, and laurel, while here and there

Owing to the selective action of running water, the richest streaks are found on the concave side of the river bends, as these points represent the region of slack water. The swift current is continually cutting out the convex side of the curves and re-depositing its burden on the inside of the next bend. The gold is coarse with rough edges, which indicates that it has not traveled far. It is mostly scale and plate gold and generally melon-seed shaped. In places the colors are very large, but no nuggets are found in the gravels.

For the most part the boulders are small, averaging under 6 in. diam., and there is no clay except in part of the overburden. There are places along the present channel where the gravel is only 4 ft. thick, and others where it is evidently at least 30 ft., but where the gravel in the

THE ABBIE J. CHAMPLIN.

ALONG ROGUE RIVER, OREGON.

along the river are orchards of apples, pears, and peaches, and vineyards of every variety of grapes. A few miles northwest of Merlin the river narrows to a gorge known as Hell Gate, and from there to the coast flows through rough country. The available dredging ground is therefore confined to Jackson and Josephine counties. The river has a velocity of from one-half to two miles per hour and is subject to sudden rises in the winter, the rainy season in Oregon.

In the early days considerable gold was won by wing-damming the river and cleaning the bedrock. At Gold Ray, while constructing a large power dam, it was necessary to build a cofferdam, and from 100 sq. ft. of bedrock thus exposed \$1750 in gold was obtained. A nugget worth \$289 was picked up years ago in Spanish gulch near the river. The pocket from which it came was never found, however. Below Grants Pass there is an ancient channel to the west of the present bed of Rogue river, in places adjoining it and in others a mile or so distant. In recent geological times the river has been in its eroding stage, leaving the old channel high and dry, and hydraulic mines on it are throwing their tailing into the present stream. These mines claim they are losing 40 to 50% of their gold, which of course is being added to the gravels of the present channel.

In Sections 2 and 11, Township 36 S., Range 7 W., the river makes a big bend, with the ancient channel cutting across the open end of the U. At the lower side of this bend bedrock is slightly above the surface of Rogue river, and a hydraulic mine at this point has exposed 75 to 100 ft. of gravel with 10 ft. of overburden. Reposing on the upturned slate bedrock is 15 ft. of a rather stiff blue gravel. One pan (small size) taken in this blue gravel gave twenty good-sized colors weighing 0.018 gm. Estimating 135 pans to the cubic yard, the value per yard would be \$1.60. The channel exposed so far is 600 to 700 ft. wide, and the back rim is not reached yet. The surface gravels were tested both by pan and rocker, and colors were always obtained wherever the gold had a chance to deposit; that is, where the sand was heavy and contained a fair sprinkling of boulders. In a few places a third or a half of a cubic yard was measured off and put through the rocker, and these tests returned an average of 25c. per cubic yard.

ancient channel is exposed by hydraulic operations it varies from 75 to 150 ft. in thickness. Bedrock consists of upturned slate beds that are hard where exposed to the river action, for the running water continually wears away any disintegrated material. But under the gravel, in places where it can be observed, the slate is soft and decomposed and could be picked to a depth of a foot or two. Benches along the river have been worked in a desultory

MAP OF OREGON.

sort of manner by means of a gasoline-driven pump and sluices. The gravel was fed to the sluices with wheelbarrows and the men cleaned up from \$2 to \$3 per day each.

The only dredge in Oregon that is working successfully and returning a profit is on Foothills creek, a tributary of the Rogue, between Gold Hill and Woodville in Jackson county. Near its junction with the river, Foothills creek spreads out in a broad fan-shaped delta, and on this tract the dredge Abbie J. Champlin, owned by the Champlin Gold Dredging Co. of Chicago, has been working for several years. Recently, however, the dredge met with a serious accident. The heavy bucket-ladder line broke and sank the boat in its pond, but it is understood that the damage will be repaired at once.

The prospecting was done with Keystone drills, there being too much water in the ground for shaft-sinking. Subsequent dredging gave slightly higher results than the test holes. The boat was built by the Allis-Chalmers Co. and is equipped with 8-ft. open-connected manganese steel buckets weighing over a ton apiece, exclusive of the link. Lighter buckets were used at first, but were found inadequate to handle the heavier boulders and were replaced by the present set at a cost of \$9000. Too light construction seems to be the principal reason for the failure of several dredges in Oregon, and future undertakings should profit by the lessons of the past and erect no more monuments.

Electricity from the Ray power-plant operates the boat; 250 hp. is used. Two 12-hour shifts of three men each are worked; a winchman, a pump and motor man, and a deckhand. The buckets are run at a speed of 7 per minute, the actual working capacity of the boat being 2000 yards per day. Bedrock is not reached and is supposed to be 100 ft. deep on the average, while the dredge digs but 40 ft. The gravel from the buckets is fed to a trommel and the boulders discharged through this over the side of the boat. The undersize passes over a set of riffles to a sump or well, whence it is elevated by a huge centrifugal pump to the tail riffles shown in the foreground of the illustration. These long sluices are supported in the centre by an auxiliary barge. The major portion of the gold, however, is caught on the boat before reaching the tail sluices.

No gold-saving tables of any kind are used, as it is claimed that the gold is all coarse enough to be saved by Hungarian riffles, though it would seem that there must be a certain amount of fine gold being lost. The gold averages 850 fine. According to the figures of the U. S. Geological Survey for 1910, \$34,010 was produced in Oregon by gold-dredging.

New York as a Metal Market

The following letter, written by J. H. Lang, recently appeared in the *American Metal Market*:

Changes recently made by the New York Metal Exchange and shortly to become effective are two in number, both relating to tin. (1) The adoption of a standard form of contract covering all kinds of trading, whether on or off the Exchange. This contract makes for clarity in dealing; defines the rights of both parties and minimizes the possibility of misunderstanding. It has already been agreed to by the leading importers and dealers, and will be generally adopted. (2) Postponement of the daily call from 12:30 to 1:30 p.m., so that the closing prices from London may be received, and operators and dealers who base their transactions thereon be fully advised.

The object of both these changes is to extend and broaden trading on the Exchange. It is believed that consumers and the trade generally will find it to their advantage to send orders to the Exchange, and that business will be chiefly done there hereafter rather than by private negotiation as at present.

On account of the new rules of the London Metal Exchange forbidding trading in Straits and Australian tin, business on the Exchange there has been greatly curtailed, and exchanges have been established in Hamburg, Berlin, Havre, and other European cities to take advantage of this situation. Most of the business done in London originates in America or is based on transactions here, and the Governors of the New York Metal Exchange would have been derelict in their duty had they not also made an effort to avail themselves of this opportunity to secure for the local institution the important position it should rightfully occupy.

It seemed wise to start with tin in the attempt to make the New York Metal Exchange what it should be and once was—the real metal market of the country and a factor in the metal markets of the world, because there is an open market for tin and considerable speculation in it, and America uses nearly half of the world's production and

three-quarters of the Straits production. New York has the men, the money, the material, and the machinery for doing the business, and there is no reason why it should not be done here. Another reason for keeping this business at home is that the rules of the London Metal Exchange permit transactions akin to what is commonly known here as 'bucketing'; that is, it is not compulsory in London to execute orders on the Exchange and buyers have no assurance that they are so executed. In fact, quite frequently they are not executed, but are taken for account of the brokers or dealers themselves, or used as offsets against other orders, a practice not sanctioned in this country. While the London Metal Exchange was revising its rules, it should have reformed this abuse.

The promoters of this movement in New York hope eventually, after trading in tin has become established, that trading in pig iron, copper, lead, and spelter will follow. The theory of restricted markets, eliminating speculation, of cutting out brokers, jobbers, and middlemen, of producers selling direct to consumers only, etc., which accompanied the consolidation era in the early nineties, will eventually be superseded by a more liberal and intelligent policy. Necessarily so, for while an individual may elect to sell only for certain prescribed deliveries, and decide to whom he will or will not sell, such methods when followed by a corporation doing an interstate business in staple commodities are of doubtful legality. It is not the policy of the state to create a corporation which may discriminate among the citizens of the state. The inventors of this system doubtless had an eye to the main chance, but are beginning to find that knowledge which comes from control of a market is of little value if it cannot be used, and it cannot be used in a market where there is no trading.

That is the situation here at the present time, and as a result all American business goes to England, encountering there the adverse conditions referred to above. From whatever motive considered, it is of decided advantage to build up the New York Metal Exchange, and it is hoped that efforts to that end will have the unanimous support of the metal trades.

A Proposed French Copper Exchange

By JAMES E. DUNNING

In January a meeting was held at Havre to discuss the establishment of a regular copper exchange. There already is a good market for spot copper at this port, and what is desired is the admission of quotations for futures. The proposals of the commission having this matter in hand comprise, among others:

"Futures shall be on a basis of 25 tons; brokerage shall be, for both spot and future delivery, $\frac{1}{8}\%$ for purchase and $\frac{1}{8}\%$ for sales; the Caisse de Liquidation (the Havre commercial clearing house) shall register all business in copper for a commission of 1 franc (\$0.193) per ton; the deposit shall be 100 francs (\$19.30) per ton; differences shall be calculated at 1 franc or loss per 100 kg. (220.46 lb.); telegraph expenses shall be calculated at 0.25 franc (\$0.05) for each contract."

The Havre Chamber of Commerce has approved the propositions made to it by the Syndicated Chamber of Sworn Brokers, for the establishment during 1912 of a committee charged with drawing up official quotations, appearing twice weekly, of copper futures. The total importations of copper into France during 1910 were 80,676 tons, of which 51,391 tons came from the United States. During this same year the copper importations at Havre amounted to 50,820 tons.—*From a Consular Report.*

THE Austrian Government has bought the only two radium mines at St. Joachimsthal, that were owned by private individuals. The purchase price is said to be \$609,000. It is estimated that the two mines will annually yield about 3 gm. of radium and 3000 kg. of uranium salts; the latter valued at \$30,000.

Agglomeration of Fine Materials

By WALTER S. LANDIS

*The earliest example of attempting to form finely divided materials into larger masses for more proper adaptation to commercial use was probably the briquetting of peat and lignite-waste at Paris by the use of clay binder. It was from this attempt that our word briquette has arisen (Fr. *la brique*), the formed masses being shaped similar to the ordinary bricks. This term does not, however, lend itself to the many shapes of such formed material as are now being produced, as few of them, outside of some of the European brown-coal products, bear any resemblance to the shape of that well known article. I have therefore chosen the term 'agglomeration' as more accurately descriptive of the products now being manufactured, this term including the molding as well as the sintering processes.

With the increasing prices of fuel and ores and the greater demand for economy in the operation of industrial plants more attention has been paid in recent years to the utilization of waste products and low-grade ores and fuels. Much of the waste has been occasioned by the inability to utilize finely-divided ores and fuels in the furnaces because they could not be kept there, or else they clogged up the furnace shaft so that gases could not be forced through under ordinary conditions of operation. As a result all the fine was thrown on the dump. Again, with the exhaustion of the richer deposits of ores, concentration of lower-grade ores becomes a necessity, and most concentrate is produced in a finely divided condition. Aside from these considerations there is also the economy in the cost of operating the plant; a furnace running on agglomerated material will have a much greater output than one working on fine. In one case the charge of an iron blast-furnace was changed from fine concentrate to briquettes and the output was increased four-fold; better results could have been obtained had facilities been at hand for taking care of the increased output.

To attempt to catalogue all the materials that have been agglomerated by one or another process is manifestly impracticable, and I have given here only a list of a few of the more important ones at present attracting attention:

I. Fuels.—In the mining and preparation of fuels like coal and lignite much fine material is produced. Also certain lignites slack and fall to pieces on storage. The agglomeration of this fine has long been practised in Europe, where fuel is scarce and expensive, and the U. S. Geological Survey and Bureau of Mines have been active in calling attention to this phase of conservation of our own fuel-supplies.

II. Concentrate.—The shaft-furnace is probably the most economical of our smelting devices when fed with lump material. Also the economy incident to the smelting of pure ores in such a furnace is too well known to merit discussion here. This has led to a wide application of ore-dressing to prepare such pure material, and since nearly all dressing operations require more or less fine crushing of the ore, it is almost a necessity that some agglomerating device be used to prepare the concentrate for advantageous blast-furnace use. In the United States the agglomeration of magnetite concentrate has received considerable application.

III. Fine Ore.—Years ago many metallic ores, particularly those of iron, were plentiful and cheap. Furnace-men would not accept fine ore, and as a consequence large quantities of this material accumulated at the mines and the furnaces. With the increasing cost of ore the heaps of fine all have increased in value and may be profitably agglomerated and sold. Moreover, the long hauls and frequent transshipments necessary with many ores in the United States cause much breakage, and this condition opens up another field for the industry.

*Abstract of a paper presented at the New York meeting of the American Institute of Mining Engineers, February 19. Preliminary edition.

IV. Flue Dust, Sweepings, Etc.—The disposal of the dust carried out of blast-furnaces has frequently offered a disposal problem quite comparable with the actual intrinsic cost of the dust to be handled. The agglomeration of this material, together with the sweepings of the plants, is now attracting the attention of the industry, and great saving would be attained by charging all such material back into the furnace in such form that it will not again be blown out. In the year 1910 the United States produced nearly 28,000,000 tons of pig iron. A conservative estimate of the flue-dust made by the blast-furnaces in the same year is 3,500,000 tons, carrying at least 35% of iron. At a low value of 4c. per unit of iron, this dust cost almost \$50,000,000 for its iron content alone, not to mention another \$1,500,000 worth of coke contained in it. Surely a process that would enable the utilization of this enormous by-product is worth attention.

V. Scrap Metal.—Even finely divided scrap metal, such as filings, chips, etc., are now being formed into briquettes for more efficient handling. Sometimes flue-dust, sweeps, etc., are agglomerated together with the metal, the whole making a mass possessing many advantages in certain branches of metallurgical treatment. No single method of procedure is applicable to the treatment of the widely different materials listed in the above five classes. In fact, the diversity of the agglomeration processes used makes it somewhat difficult to outline a simple classification which will be comprehensive, and the classification here proposed may sacrifice completeness for simplicity. In general the agglomeration processes may be divided into:

I. Those utilizing certain properties in the material for producing the desired coherence.

II. Those obtaining coherence through the addition of a foreign substance or binder.

Under group I are four classes:

1. Certain materials when moistened with water and molded into form and dried possess considerable coherence. Ores carrying soluble salts, clay, easily hydrated compounds, etc., are frequently found amenable to this simple treatment. A few iron ores and roasted products are actually treated in this manner, but the product possesses the great disadvantage that on heating to a temperature sufficiently high to drive off the water the briquettes fall to pieces.

2. Pressure greatly assists in developing the cohering power of many materials; probably if a high enough pressure could be uniformly applied throughout the mass to be formed, all substances would agglomerate under this treatment, but the use of pressure alone is limited to but very few cases in practice. Sometimes the best results are obtained on dry materials, sometimes a certain amount of moisture is necessary; the pressure so far used runs up to about 2000 atmospheres.

3. All materials on being heated to a high enough temperature pass through a pasty or semi-fused state and cohere to such a degree that on cooling a more or less firm mass results. This phenomenon is called sintering. If done in a rotating furnace or rotary kiln the sticky masses roll together like snowballs, and small round particles are formed which are called 'nodules'; the process is called 'nodularizing.' This same sintering property of a material may be taken advantage of by molding the material into briquettes, using only a slight pressure to insure filling the mold, then burning the briquette so formed at a temperature that will insure cohesion. This is the principle of the well-known Gröndal process.

4. This class is represented by processes employing a combination of pressure and sintering. It is difficult to fix exactly the limits which differentiate a process truly belonging to this fourth class from one of the third, since the difference is wholly in the degree of pressure employed. I have chosen arbitrarily to place in this fourth class all processes which use pressures exceeding 30 atmospheres for the formation of the briquette. The best example of this fourth class is the originally Ronay process as installed at Catasauqua, Pennsylvania, in 1904. The Ronay process has since been modified by limiting the attempts to apply it to ores which will agglomerate under application of high

pressure alone, without the necessity of afterward sintering them.

Under group 11 are included the greatest developments of the briquetting processes. The use of a binder for causing the agglomeration much simplifies the whole operation, as the binder acts like a cementing medium to hold the inert particles of material together. It is almost impossible to list all the binders that have been used; a few of them are clay, lime, ground slags, natural and portland cements, water-glass, kieselguhr, carnallite, tar, pitch, asphalt, petroleum, sulphite residues, naphthaline, paraffine, molasses, resin, starch. Most of these act of themselves without taking further precautions other than to insure a thorough mixing with the material to be briquetted. Others require that the briquettes be aged, or even heated after formation, to temperatures up even to redness.

The operations of group 11 may therefore be divided into three sub-classes: (a) processes in which the binder is mixed with fine and molded under low pressure; (b) processes in which higher pressures are used along with the binder; (c) processes in which a binder and pressure are used together, with a subsequent heat treatment. The first two are self-explanatory; the last may be subdivided into processes which use a baking in superheated steam, or even agglomerating in a furnace, such as, for instance, where lime is added and later passed through an agglomerating press.

It does not seem to me that proper attention has always been paid to the selection of a binder for the particular case at hand. Too often is the intrinsic cost of the binder the main item in its selection, the subsequent cost which it entails in passing through the smelting or refining furnace being entirely overlooked. The waste-product possessing binding power may become very costly if it entails the production of an extra amount of slag to be smelted, or introduces in the furnace product a small amount of impurity which is difficult to remove afterward. Where limestone is an essential ingredient of the furnace charge, lime can be profitably used in considerable quantities as a binder. If the materials are self-fluxing, a minimum of binder should be used, no matter what its composition may be.

Pressure increases the effectiveness of all binders, enabling one to obtain the desired results with the use of a minimum of extraneous material. Around metallurgical works, where power is usually cheap, an extensive investigation of the most economical balance between binder and pressure should be carried out. The importance of the industry is such that soon some enterprising briquetting company will erect a central testing plant similar to an ore-testing laboratory, and such questions will be absolutely settled for each particular case at a minimum cost.

The physical properties which a briquette should have may be summed up as follows: It should be strong enough to stand handling without undue breakage. The simplest test to determine this property is a drop test. A number of briquettes should be dropped from a height of at least 6 ft. upon a hard stone surface. Not over 25% of the number so dropped should break, and none of the broken ones should fall to powder of the original texture of the material before briquetting. The breaking of a briquette into two or three pieces is not a serious matter, but in no case should it pulverize.

Where the agglomerated material is to be stored or transported before use, a weathering test should be applied. Storage in the open which subjects the agglomerated material to rain, snow, frost, and sunshine should be resorted to, since none of these agencies affect a well made product. For proper reduction in the shaft-furnace, the agglomerated material should be porous. Where briquettes are to be tested, the dropping of water from a measuring device upon the known volume briquette gives a fair test if care be taken to do it slowly and carefully, so that no more is measured out than is absorbed by the mass. A simpler and easier test is made by weighing the agglomerated mass and submerging it under water for at least 24 hr. and again weighing. This may be hastened by assisting in the displacement of the entrapped air by performing the ab-

sorption under a vacuum. A good briquette should show a porosity of 20%; that is, should take up 20% of its volume of water. One of the greatest drawbacks to the nodularizing process is that the nodules are non-porous, and therefore difficult to reduce. The addition of lime to the charge of the nodularizing kiln somewhat counteracts this tendency to form non-porous nodules, but unless carefully made the nodules will not withstand some of the other tests recommended.

Disintegration should not follow the exposure to water-vapor at 150°C. This test is best performed by submitting the briquette to a steam-pressure of 60 lb. per sq. in. for several hours. The top of the furnace contains vapor at this temperature, and care must be taken to submit briquettes containing certain binders to this test, since some of them will fall to pieces under the action of hot water-vapor. Briquettes should not disintegrate when heated to redness. The test can best be done in a muffle, and, if conditions permit, should be in an atmosphere of carbon monoxide and dioxide. Many of the hydrated briquettes, or those bound together by hydrating influences, will not stand this test. Of course, it is understood that no briquette should contain a binder that exerts a harmful influence on the product of the furnace. No sulphur compound, for instance, should ever be introduced into a briquette to go into an iron furnace.

Cornish Tin Mines

The St. Ives Consolidated, an aggregation of old tin properties in the neighborhood of St. Ives, Cornwall, under the control of the Schiff-Dietzsch group, is asking for more capital and offering debentures for subscription. The same group now wants £60,000 for their St. Agnes Consolidated, which was formed more recently to acquire the West Kitty and other properties in the St. Agnes district. Reports by Ferdinand Dietzsch, the company's consulting engineer, and by William Thomas, of Camborne, have recently been issued. The further funds are required to provide additional stamping power and equipment for West Kitty, and presumably in part to meet existing liabilities, seeing that the consulting engineer estimates that an expenditure of £39,052 will cover his proposals. The capital of the company is £175,000, of which £137,500 has been issued, and £125,000 in 6% participating bonds has been authorized, and £35,000 subscribed. If the debentures now offered are all taken up, the liabilities of the company will be £232,500. In spite of all the possibilities of West Kitty and East Blue Hills, the only properties of the group receiving attention, it will be many a day before the profits will be sufficient to pay interest and dividends on so great a sum. Mr. Thomas speaks highly of the recent discovery in the cross-cut at the 80-ft. level between the Friendly and Reynolds sections, and he anticipates that by deepening the shafts on those properties the lode will be intersected in each. The letter accompanying the reports states that "when the full 60 stamps are completed and all at work, it is estimated by the engineers that they can deal with at least 200 tons of ore per day, which, taken at the moderate assay-value of 45 lb. of tin oxide per ton, would yield about 4 tons of tin oxide per day or 100 tons per month, equal to over £10,000 in value." In face of the fact that the ore being milled at West Kitty shows a recovery of less than 14 lb. per ton, and that only low-grade ore has so far been opened up at East Blue Hills, 45 lb. recovery on a monthly tonnage of about 5000 tons is an optimistic anticipation, especially at this stage in the development of the recent discovery. But West Kitty has great possibilities, and if the company had been moderately capitalized, investors would have had no reason to regret their connection with the property.

The report of the South African Gold Trust for the year ended December 31, 1911, shows a net profit of £107,976. A final dividend of 2s. per share has been declared, making a total of 3s. 6d. for the year, and £88,804 carried forward.

Gold and Silver for Jewelry Manufacture

The raw gold and silver used in jewelry manufacture in Germany are obtained from the banks or from the smelters, the important one of the latter being at Frankfort. It is a very interesting fact that gold coins, such as 10-mark and 20-mark pieces, having a fineness of 900, are used largely as material, and the imperial mint frequently turns out these coins in vain, as they remain in circulation for only a short time. The local branch of the Reichsbank issues 20-mark pieces unstamped at the price of 20.06 marks (\$4.7743). This gold is thus money and material at the same time, and the manufacturer is in a position to melt the credit afforded him by the banker. Naturally the business standing of the various merchants is watched closely.

Many concerns have come into being through methods of reclaiming and using waste gold. By means of various processes, some very complicated, the particles of gold are extracted from the wash-water, the workmen's overalls and towels, polishing cloths, and other material. Some proprietors of these concerns furnish manufacturers with free aprons, blouses, polishing cloths, towels, and head cloths for women who do polishing work, and sometimes pay for this privilege, in return for which they retain the gold they are able to recover.

The price of gold in July 1911 was \$666.40 per kilogram (2.2 lb.), at which it has stood for some time. The price of silver is subject to great variation. In 1905 it was \$18.33 to \$23.09 per kg. Platinum costs \$1190 to \$1356.60 per kg. While in 1892 platinum could be bought for \$261.80 per kg., or half the price of gold, today it costs double the price. Platinum is used more and more in the manufacture of jewelry, and in Pforzheim \$1,190,000 worth is used in a year.

There are great losses in the manufacture of jewelry, and on an average, in a medium-size factory, unsold goods of a value of about \$2380 must annually be melted up, which means a loss of about \$1666 in wages and manufacturing costs.

According to a British Government report under the census of production act, the actual cost of production, without the manufacturers' profit, of certain classes of jewelry in Great Britain in 1910 was as follows: Goods made wholly or in part of gold, including mounted articles, £495,000 (\$2,408,900); gold leaf and gold thread £88,000 (\$428,250); goods made wholly or in part of silver, including mounted articles, £1,844,000 (\$8,973,825); stampings, handles, and other parts for silver goods, £15,000 (\$73,000); total gold, silver, and electroplated goods, £4,939,000 (\$24,035,650); gold chains, £654,000 (\$3,182,700); silver chains, £49,000 (\$238,450); imitation, £55,000 (\$267,650); other jewelry, gold, and platinum, £1,762,000 (\$8,574,775); silver, £177,000 (\$861,370) imitation, £231,000 (\$1,124,160); gold and silver articles not separately distinguished, £240,000 (\$1,167,960); total jewelry of all kinds, £3,292,900 (\$16,020,500); total value of all goods made of precious metals and work done in the United Kingdom, £8,563,000 (\$41,671,850).

The value of the jewelry manufactured in the United States in 1909 was over \$80,000,000, of which \$36,000,000 represents the cost of the raw materials used.--*Daily Consular and Trade Reports*.

Federated Malay States Gold Output

The quantity of gold exported during the month of December 1911 was 768 oz. from Raub. The total amount exported during previous months of the year was:

	Ounces.
From Seremban	241.79
From Raub	6,909.00
Total	7,150.79
This, with 768 oz. exported during December, gives the	

total of 7918.79 oz. exported for the year. The duty collected was ₦2105.48. This includes ₦377.50 as the amount of royalty collected on gold not exported from Kuala Lipis. It is reported that the amount of gold purchased by gold buyers in Batang Padang (Perak) during the year was 1077.6 tahils, which is equivalent to 1309.57 oz. No duty or royalty was collected on this. In 1910 the amount reported to have been purchased was 898.5 oz. Comparative figures of gold exported and duty collected are as follows:

	1911.	1910.
Gold exported (oz.).....	7,918.79	15,868½
Duty collected	₦2,105.48	₦14,091.64

There is a decrease of 7949.71 oz. in 1911 against 1910, and a decrease of ₦11,986.16 in the amount of duty collected.—*In Tinland*.

Trestles for Pipe-Lines

Where pipe-lines have to be laid across rolling country, it is obviously impossible to keep the pipes always just beneath the surface, for the line of pipe should be kept as nearly straight as possible. This is not because a straight line is the shortest distance, thereby economizing in pipe and fittings, for the cost of trestles and deep cuts will often be much greater than the cost of the extra length of pipe required in following the surface. But the important point is that a loss of head results from every change in

INEXPENSIVE PIPE TRESTLE.

direction of the flowing stream, and unless the line of flow is kept straight or in gentle curves, a prohibitive amount of pressure head may be lost. The line of pipe must be kept in sweeping curves, and it will be worth while to spend considerable sums to secure this. High points may be crossed by deep trenches, while narrow gulches may be spanned by a simple trestle, like that shown in the illustration. This is made of hewn or split timber, obtained nearby, the simple form of Howe truss serving for the central span. The railroad bridge in the background is a similar, but more elaborate, type of construction and the two together illustrate the fundamental principle of engineering: making a dollar go as far as possible. The light, cheap construction of the pipe trestle is amply good enough for the service required of it, while the heavier service on the railroad necessitates heavier and more expensive construction.

The gentle sag of the pipe-line over the trestle serves, to a slight extent, in compensating for expansion and contraction due to changes in temperature, where these are not too extreme. The water flowing through the pipe is not ordinarily in any danger of freezing, unless the velocity of flow is very slow. Where freezing is likely to occur the pipe can be housed in roughly with thin boards and the space between filled with moss or any other non-conducting material that is convenient and cheap. Air vents should be provided at the top of each vertical curve in the line.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Is 'Cheap' Labor Economical?

The Editor:

Sir—It is, of course, a truism that a definition of terms is required in discussing this subject, as stated by C. R. Gent in his interesting communication which appears in the December 30 issue of your paper. No abstract comparison, can, in fact, be made as to the merits of African, Chinese, Indian, or Mexican labor and that of the 'white' races from the point of view of economy. Concrete cases, either of mines, or of certain limited districts of a given country, must be taken if positive and conclusive data are to be obtained as to the relative working efficiency of so-called 'cheap' and 'dear' labor. In each case the labor will be dear or cheap according to the results obtained, that is, ultimate results in the shape of decreased costs, or their reciprocal—increased dividends. It is hardly a fair statement of the case to say, as Mr. Gent does, "that when a mine will not pay for the skilled labor that is necessary to properly extract the ore, it is time to close down." With labor slightly less skilled, but considerably lower in price, not only might it not be necessary to close the mine down, but lower working costs and increased profits might result from the change.

As regards Mexico, let us take the concrete case of the Natividad mine, in the district of Ixtlan, Oaxaca, where an approved system of working costs is kept and available for careful comparisons. Here all drilling is done by hand, although ample water power could have been harnessed for the purpose. The rock is harder than is to be found in most of the mines of Mexico. There is no doubt but that more could be got out of the labor supply and better economy by using machine drills both for development and stoping. The economy here in stoping operations would be much less than in development, as the costs are now very low, as will be shown, for in development so much depends on being able to drift rapidly, and machine drilling becomes important. So much for the drills. Now as to the labor.

From an economical point of view the efficiency of this can be measured by the cost of the work. In the great variations that occur in mining work, there is always a difficulty in comparing results even under similar conditions, but it is possible to get at it fairly closely, particularly in such expenses as driving costs, where nothing but the hardness of the rock and the cost of supplies are the variables that have to be taken into consideration in order to gauge the other variable of labor. And if a hard rock can be driven in the United States for \$10 per foot and in Mexico for \$10, there can be no argument as to the comparative 'cheapness' of the labor in this case. The figures given below will still further strengthen this case. Costs per ton of ore mined are not generally comparable, because many mines have wide veins, timbering costs differ enormously, and there are other variable factors. The following costs will be seen to be very low in the case of the mine in question, as conditions are almost all unfavorable, namely, a hard vein, false walls requiring much timbering (700,000 ft. of timber in the costs shown), high cost of supplies, a small tonnage, and a large amount of development necessary per ton of ore developed. The other factor, labor costs, stands out very strongly. The cost is the total for 1910 reduced to United States currency and the short 2000-lb. ton, and includes development. As regards the driving cost, it is also an average, taken on over 3000 ft. of work under all conditions. Some of the places in the upper part of the mine have soft rock and would help

to bring costs down, but most of the work was done in hard andesite and indurated slate.

Shaft-sinking at the Natividad mine, 3 compartments, cost per foot.....	\$22.55
Total mining cost per ton (1910).....	2.74
“ “ “ (1911) Jan. to June....	3.14
Average cost of shafts, drifts, raises, winzes, etc., per lineal foot	6.94

(The last cost is made up on 1716 ft. of development done January to July 1911, including 118 ft. of sinking a 7 by 15-ft. shaft and 313 ft. of winzes and raises. Cost includes all expenses against development.)

Compare now these costs with those of other important mining centres, such as those given by J. R. Finlay, for example, in his 'Cost of Mining', covering four districts (Rand, Goldfield, Kolar, and Cripple Creek), and then decide whether the labor with which such a result is achieved is cheap or the reverse. These figures bear out the opinions of many that development work can be done in Mexico almost for the amount in pesos which it would cost in dollars in the United States; and this is directly attributable to the labor. As to machine work, many cases can be recalled where Mexicans did nicely on machine contracts at a price no American would take, although many offered.

But there is another important point, seldom touched upon in connection with Mexican labor, and doubtless the same is true of native labor wherever employed, and that is its abominable handling by American or foreign overseers, speaking, of course, here, from a purely economical point of view. Starting on the principle that labor is cheap, they so often make it vastly more expensive than any other in the world, solely by their mismanagement of it. The shift-boss who does not profess to speak Spanish "but can make himself perfectly understood by the natives" as the saying is, has his gang of men stand idle for an hour while he attempts to give the poor benighted heathen an object lesson as to how the work should be done. This type of man would no doubt consider Mexican labor 'dear', and so do the stockholders who have to pay for it. This is a fair example, and it is repeated *ad libitum* throughout this country. And when the system is extended to every grade and class of work, and to large companies, the aggregate lack of efficiency is very great. The South African plan of depriving the stockholders of companies of their fair dividends (there is little enough profit as it is), in forcing costs up, by making it illegal for the black to do the work of the white, when the experience with the Chinese, and during strikes, has shown that the former could do it as well (dollar for dollar) as the latter, and far cheaper, is not particularly to be commended. The result is that while white labor is employed underground in South Africa doing work which the blacks and Chinese could do cheaper, the mines are closed down. Much the same atmosphere exists in Mexico in this respect; that is, among a certain class of 'white men', there are those below who fear they would lose their jobs, or that the work would be lowered in dignity if the Mexicans could do it, and those above, who prefer to have men under them to whom they can explain their orders without fear of misunderstanding from linguistic shortcomings. They are not themselves footing the bill.

There is no doubt but that very few attempts are made, in mining, to get the best results out of the native labor. In fact, the usual thing is to work the other way. And among Mexicans themselves there undoubtedly exists a perfect knowledge of the fact that self-respecting Mexicans, the very element that should be encouraged, would rather work at anything else than in a mine run on the usual English-speaking plan, and that only those who do not take offense at the continual punctuation of orders with offensive expressions are those who are preferred in most foreign companies. There are doubtless many exceptions to the rule, but, as a general thing, there is no doubt that the native labor is about as poorly handled as it well could be. The whole thing hinges upon whether the companies are to be worked for the benefit of the stock-

holders, or for that of those who want to hold their jobs. That all 'cheap' labor furnished by Mexicans is bad, would be about as good a generalization as to say that all high-priced labor is good, and if a mine is to be worked in the interests of the stockholders (the only light that is reasonable), Mexican labor should be handled by Mexicans, so far as it is economical to do so, that is to say so far as it is possible to find competent Mexicans to do the work. Patriots will never be lacking who will spread the news that such a method has worked to the sorrow of the company that does such a thing, but facts point the other way. All this does not mean that a good white man, with a good drill and plenty of air behind it, will not do work that will throw everything the average Mexican can do, into the shade. He will run away from him, of course. But a good Mexican machine man will take a contract on the same work at a figure upon which the American would starve, and will stick to it. This is the ultimate test of cheapness.

Speaking of the labor problem in Mexico generally, it requires a lot of attention and patience, and it needs capable men who are willing and able to explain and to teach where necessary, the work that has to be done, if the natives are to be educated and built up to modern requirements, and the desired results obtained. To educate the Mexican up to doing his work properly is not going to deprive any white man of his position, for cheaper costs will allow industrial and mining expansion, and there is still room in the world for all. It is hard to imagine any subject of greater importance to the mining industry everywhere than the one under discussion. On a proper grasp of it depends, in many cases, whether an enterprise shall be a failure or a success.

GEORGE SPENCE.

Mexico City, Mexico, February 28.

Nicaragua and Its Possibilities

The Editor:

Sir—The paper on the geology of the Pis Pis district, by Osear H. Hershey, is one of the most interesting communications regarding that district that I have read in a long time. In October 1910 I had the pleasure of preparing a paper for the American Institute of Mining Engineers on 'Mining in Nicaragua.' Up to that time hardly anyone had written on the mineral resources of this interesting country. The increasing number of papers dealing with Nicaragua and its mines, appearing not only in your journal, but in the other leading publications as well, shows the interest that is being taken in this republic.

One of the reasons why I so appreciated Mr. Hershey's paper is that it agrees so well with my own conclusions, formed after a year spent in Nicaragua. Mr. Hershey's remark, "In short, the geology of the Pis Pis district is generally favorable to the future of its mines," is a very important statement. What impressed me so much was the fact that indications are found of the same kind of formation as at Pis Pis, in other places south of the district, approximately parallel with the coast line. In the Bana Cruz country, about 15 to 18 miles southeast of Siempre Viva, encouraging indications of gold can be found; farther along, in the Oconguas district, there are a large number of prospects. In this district I opened a mine showing, in a cross-cut, an assay value of \$11 (United States currency), over 33-ft. width. In the Oconguas district most interesting deposits of gold occur in the form of small veins and veinlets, in a highly crystalline limestone. I have seen buckets of picked ore from these tiny veins with the most remarkable display of visible gold.

Far down toward Costa Rica is the La Luz y Los Angeles mine, which, in my opinion, is the most interesting mine in Nicaragua, with the possible exception of the Bonanza. La Luz is probably the premier gold producer today of Nicaragua. Still farther south, on the Rama river, is the Topaz mine, which has promised so much and so far has accomplished so little. To go over such a big stretch of country and find so much gold is certainly en-

couraging and makes the engineer hope for the future, in spite of the disappointments of the past and the drawbacks of the present.

One point in regard to the gold veins of Nicaragua may be mentioned, and that is the large amount of silver associated with the gold. In the Pis Pis district it is seldom that the gold will run as high as 700 in fineness; in the Oconguas district I found that the gold ran about 350 to 400 fine. Mr. Hershey brings out very well the fact that the geology of the Pis Pis district indicates that Nicaragua will have mines requiring a large tonnage and low working cost. It is not a poor man's country, in spite of what the prospectors have already accomplished down there. Had these large veins been worked from the start by large corporations with plenty of money and experience, Nicaragua today would be noted as a gold producer. While the economic conditions have in the past been so bad and are at present unsatisfactory, and while the prices often asked for mere prospects in Nicaragua are absurd, it is encouraging to hear men like Mr. Hershey say that the geology of the country is so favorable.

Cyanidation at Silverton

The Editor:

Sir—Warren A. Prosser, secretary of the Silverton Commercial Club, takes exception to one sentence in my January 20 letter, and attempts to prove it untrue by the use of names prominent in cyanidation. I do not attempt to deny, nor did my letter, that some investigation has been carried on here by competent men, and I do not pretend to criticize the work of such men as Messrs. Callow, Argall, Milliken, and some of the others named, nor have I any quarrel with Messrs. Root, Norton, and Schaefer. I merely desire to call the attention of the public to the dangers arising from too hasty installation of cyanide plants and the extravagant statements of those who are not thoroughly informed. Cyanidation may solve some of our metallurgical problems, but much thought must be given to the design of proper plants. Already too many people believe that the only thing necessary for success with a telluride, or other gold and silver ore is a crushing plant, a vat for applying the cyanide, a zinc-box, and a retort for reducing the metals to bullion.

SILVERTON CORRESPONDENT.

The Estimation of Tonnage

The Editor:

Sir—In your issue of February 24 T. B. Greenfield described at some length the practical difficulties met in determining the specific gravity of an ore, and in the same issue A. W. Allen describes methods which may be followed. Neither of these gentlemen allude to a factor which may easily be a source of error in such determinations, namely, the change in specific gravity of an ore due to the formation of colloid hydrates during fine grinding. According to the method of computation, this may be a source of error, or it may not. The mass (in the exact sense) of the ore is clearly not affected by chemical reactions, but its volume and, therefore, its specific gravity may be considerably altered. Where the solid material is separated, dried, and weighed the water of hydration would largely be lost, though changes due to oxidation may be of some effect, and the resultant error will be probably very small. But where, in the case of a slime, the method suggested by Mr. Allen on page 309 of your issue of February 24 is followed, x will represent the percentage of ore in the slime, but *not* the percentage of solid in the slime. Exact quantitative determinations of the influence of colloids on ore-dressing problems is much needed, and it is to be hoped that research along these lines may be undertaken in some of our technical schools.

San Francisco, March 18.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

NEFT-GIL is a hydrocarbon, occurring abundantly in the naphtha region of Cheleken island, in the Caspian sea. It is a mixture of paraffines and a resin, consisting of 66% of a wax-like substance insoluble in alcohol, 18% soluble in alcohol, and 13 2/3% resin. It has a chocolate brown color, and melts at 75° Centigrade.

APPPLICATION of liquid air in rescue work was devised by M. Süß, the inventor of the Aerolith apparatus; but in spite of the interest aroused by this apparatus in all who are interested in such work, the apparatus itself has not made any headway. The reason for this is to be found in the difficulty of handling and transporting liquid air.

A PIPE in limestone or granite, giving a small surface only to work on, and being probably irregular both in shape and course, is extremely hard to prospect by any method; in fact, the only thing to do is to follow the ore wherever it goes, which will generally mean that the pipe is worked out as it is followed up, a proceeding that hardly fits in with ordinary ideas of prospecting. Real prospecting, however, will be accomplished by not throwing up the work when the ore becomes unprofitable, but by pushing forward steadily as long as there is ore in the face, or minerals, such as sulphides and fluor spar in limestone, and tourmaline in granite, that indicate a possibility of more ore existing beyond.

AGREEMENTS made by patent applicants to deed certain portions of claims or rights after patent to those threatening adverse in consideration of no adverse being made, are sound and valid as between two claimants for lode claims. An agreement to deed a claimed lode within the limits of a placer for which patent had been asked, would raise such question as to the good faith of the placer applicant, in that he thereby recognized the lode in question, as probably to require exclusion of the lode ground from the placer application, or, in view of the difference in price of placer and lode ground, to afford basis for vitiating the patent on the basis of fraud. The law with regard to known lodes in placers has not been entirely tested in the courts, as regards discovery before patent, and the good faith of the applicant for placer patent would be especially important.

ASSessment work to the value of \$100 is required by the Federal statute within each calendar year succeeding location. Various state statutes require specific forms of location notices and the filing for record of a location notice within a specific time after location. Whether, in event of a location having been made in December 1910, for example, and the location notice being filed in the succeeding January, annual work would be necessary in 1911, seems never to have been decided. Apparently such work would be necessary, since the Federal statutes do not require filing of the notice, and therefore, so far as the requirements of the United States are concerned, the location was complete in December. Certainly this would be the interpretation called for by the spirit of the law. The intent of the latter is that anyone holding a mineral claim on public land should do work, at least to the value of \$100 per year, in an effort to demonstrate its value.

RUSHING the can has come to connote a hasty trip of the pitcher to the bar, but in the lead and zinc districts of the Mississippi Valley the phrase might equally well be applied to rapid hoisting. In these districts the use of cages and cars is unusual. Ore is ordinarily hoisted in buckets or 'cans,' to apply the local name. These cans are handled under ground on small four-wheeled trucks and

are hoisted by friction hoists set in the head-gear over the shaft and above the mill-bins. Extremely rapid work is done with this simple and light equipment. At the Vinegar Hill mine near Galena, Illinois, 1019 cans of 1000 lb. capacity were hoisted recently in a 9-hour shift. The shaft here is 200 ft. deep. In such work it is customary to have one man at the top to run the engine and dump the buckets and another at the bottom to land the empty cans and hook on the loaded ones. Generally hoisting is done without signals. The bucket is dropped to the bottom and the man at that point must unhook the rope and attach it to the loaded can within a given time determined by the engineer.

BBROWN-PRINTS are prints similar to blue-prints, except that they are made on brown-print paper instead of blue-print paper. If a print be made on brown-print paper from a tracing as a negative, the print will show white lines on a dark brown background. This paper requires a little longer exposure than rapid blue-print paper, and must be washed three times, first in clear water from three to five minutes, then in a solution of fixing salt and water for about the same time, and finally are rinsed thoroughly in clear running water. The fixing salt is hyposulphite of soda, and a can comes with every roll of paper. Use in the proportion of half an ounce to a quart of water. From the brown prints made as above, showing white lines on a brown ground, other prints can be made by using the brown print instead of a tracing. If these other prints be made on the same kind of paper—brown-print paper—they will show brown lines on a white ground. If ordinary blue-print paper be used, there will be blue lines on a white ground. These secondary prints require a longer exposure and must be carefully made to insure clearness. The white ground is convenient, because additions can be made on the print in pencil or ink. Brown-prints are much used because of the fact that tracing can be made and kept at a central office and brown prints from them distributed to the various agencies or branch houses which are then enabled to make for themselves as many duplicates as are required.

THE use of graphite in the manufacture of pencils is probably both its oldest and its best known application. This industry in Germany and England is several centuries old, and many of the modern factories manufacture hundreds of varieties of pencils, yet the percentage of graphite used for this purpose is not large, being undoubtedly less than 10% of the world's production, and one authority estimates it is low as 4%. In this industry the physical character of the graphite is of great importance. Crystalline graphite, however pure, would, if used alone, yield a 'lead' that would slip over the paper without leaving more than a faint streak. Furthermore, it is almost impossible to grind the easily cleavable flake graphite into a powder of the fineness and evenness of grain requisite for the better grades of pencils. The purer grades of amorphous graphite constitute the bulk of the material used in pencil manufacture. For some of the cheaper pencils only one kind of graphite is used, but the graphite for pencils of the better grades is a careful blend of several kinds. One blend, for example, contains about one-third Ceylon graphite, one-third Bohemian graphite, and one-third Mexican graphite. The Ceylon graphite adds to the smoothness of the 'lead,' the Bohemian graphite being added for its blackness. Graphite when used for pencils is mixed with carefully refined clay, which is usually imported from Germany; no domestic clay has yet been found entirely suitable for pencil manufacture. The more graphite and the less clay the softer the pencil; the less graphite and the more clay the harder the pencil. The cores of softer pencils are usually made larger than those of the harder ones in order to give them equal tensile strength. For a pencil of medium hardness (11B) about one-third clay is commonly used. The wet mixture of clay and graphite is worked and reworked until it is so pliable that it can be looped in coils and even tied in loose knots.

BLACK HILLS, SOUTH DAKOTA

MOGUL M. CO.'S CYANIDE PLANT DAMAGED BY FIRE.—COMPANY TO REBUILD.—WINTER IS UNUSUALLY SEVERE.—WASP MILL RESUMES OPERATION.

Fire on March 8 damaged the cyanide plant of the Mogul M. Co. at Pluma, to the extent of probably \$75,000. Insurance to the amount of \$155,000 was carried on the mill, assay office, machine-shop, warehouse, office building, and other property at Pluma, covering the loss. The fire was discovered about 4 o'clock in the afternoon, the origin being unknown, but it is thought electric wires were crossed near the bottom of the mill. Before the employees could get the fire hose coupled and in action, the flames had spread until a large portion of the roof was blazing. A visit to the plant shows the Moore process department, sand leaching tanks and building, and precipitation department to be practically unharmed. The rolls and Chilean mills are in fair shape, and can be used again. They rested on concrete foundations, near the bottom of the mill, and the flames were for the most part far above

WASP NO. 2 MILL.

them, in the roof and superstructure. The settlers, Dorr thickeners, crushers, crusher motors, sampling-room, ore bins, and about two-thirds of the mill building were destroyed beyond repair. J. V. N. Dorr, general manager for the company, states that it is the intention of the directors immediately to rebuild the plant, as soon as adjustments are made with the insurance companies. In the meantime ore shipments are being made at the rate of 75 to 100 tons per day to the L. D. & W. mill, at Terry, and negotiations are pending which may result in additional ores being handled elsewhere. The fire was confined to the mill, and none of the outlying buildings, such as the assay office, machine-shop, or office, were injured.

The Black Hills has experienced one of the most severe winters in its history. Old-timers say that the snowfall is greater than in any previous winter—in fact, it is the greatest since Government weather-observing stations were established. E. F. Irwin, timekeeper for the Homestake company at Lead, is a voluntary observer, under the Government Weather Bureau, and he reports that in the past five months (up to March 15) nearly 9 ft. of snow has fallen. Most of this is still lying on the ground and bids fair to be there for several months yet. The railroads have had an especially hard time of it, and have only kept open those tracks which were in constant use. On March 12, after the Mogul M. Co. had decided to ship its ore to the L. D. & W. mill, the Northwestern was called upon to open some of its spurs which had been unused this winter. In places the snow was 17 ft. deep and solidly packed. From present indications there will be a great abundance of water for mining operations during the coming summer.

The Wasp No. 2 mill is operating steadily again, after a shut-down caused by severe winter weather. Paul Danckwardt has resigned as superintendent of the Black Hills Smelting Co., and his successor is expected soon. The North Homestake company is cross-cutting both east and west from the bottom, or 620-ft., level of the shaft, to develop veins which were found in diamond-drilling. Three shifts of men are employed, and the work is being hastened in every way. It is expected that the full volume of available water will be turned into the Homestake hydro-electric plant on March 15, when the entire plant, including the generating station, will be given a test. As has been noted previously in these columns, the plant is practically ready to run.

RHODESIA

GOLD OUTPUT FOR THE YEAR.—CONSERVATIVE DEVELOPMENT.—OUTLOOK FOR 1912.—SPREAD OF MINERS' PHTHISIS.

The gold output of southern Rhodesia for the month of December has been declared by the Chamber of Mines, and the production for the whole year can be computed. It amounted to £2,647,895, an increase of £79,697 over 1910, and £24,186 more than the previous record year, 1909. This result must be adjudged satisfactory from every point of view. The year 1910 was characterized by the praises of Rhodesia being sounded by loud trumpets from the housetops, while 1911 has been singularly free from excitement, and there has been none of the feverish rush of the two preceding years. In fact, the outstanding feature of 1911 has been a quiet, unostentatious policy of development. This is what Rhodesia has been in sad need of for a long while past, and it is a matter for all-around congratulation that during the past twelve months the ore reserves of Charterland mines have been greatly augmented, while, at the same time, the gold output has been increased and there has been a marked improvement in dividends. Excluding small syndicates, mining development and finance companies paid £954,613 in dividends, against £883,000 in 1910. As regards other branches of the mineral industry, there has been a gratifying development in the direction of base metals. The existence of cassiterite in Mashonaland has been established, and, while it is as yet much too early to make any predictions as to the future of the tin industry in Rhodesia, it may be stated that in certain localities the indications are very promising. With regard to chrome iron ore, there has been a year of steady work, and production exports through Beira have increased. The outstanding feature in the coal trade has been the reduction of prices by the Wankie Colliery Co., which is, at the present day, the only producing concern in Rhodesia. The Colliery company hopes to sell a much larger output in consequence. Another important development in connection with Rhodesian coal mining has been the preliminary exploitation of a large coal concession by the Consolidated Gold Fields of South Africa.

The outlook for 1912 is altogether a promising one, although one is not justified in anticipating any remarkable increase in output. The fly in the ointment (and a very large and undesirable fly it is, too) is the labor problem. The Rhodesian Native Labor Bureau has been reorganized and everything possible is being done to better the supply. Despite all this, however, the demand greatly exceeds the supply, and probably to the end of 1912 things will be but little better than they are at the beginning.

Hitherto Rhodesia has been practically free of miners' phthisis; at least, very little is heard of this disease in the country. It is, therefore, distressing to observe that in the last report on the public health, issued by the British South Africa Co., reference is made to the prevalence of this dread malady in certain districts. Unfortunately, no statistics are given, and from the report in question it is not possible to gauge to any definite degree the accuracy of the identification of silicosis in southern Rhodesia. The district surgeon of Hartley, in the course of his report, draws attention to the increasing number of phthisical workers in that area, but he asserts that phthisis is confined

to miners who have worked on the Rand. Miners' phthisis has proved such a terrible obstacle to the advance of the industry in the Transvaal that the Rhodesian government might be expected to take immediate steps to investigate the whole question and to ascertain whether the first seeds of the disease were brought from the Witwatersrand.

LONDON

DOLCOATH REPORT SHOWS REDUCTION IN COSTS.—ARIZONA COPPER PAYING DIVIDENDS AT RATE OF 50%.—COLOMBIA GOLD MINING.

The results of operations at Dolcoath, the premier tin mine of Cornwall, are of perennial interest. For some time now I have been sending news as to the improvements effected in mechanical equipment, both in the mine and in the metallurgical plant. The new deep-level shaft, the 'Williams,' has been in operation for some months and the electrical and pumping plant lately has been put in commission. Since the first of the year an unusual influx of water has impeded operations, but things have once more arrived at normal state. The full figures for the results during the second half of 1911 are now available, and by far the most important feature is the fall in the cost. The tonnage crushed was 46,343, and the recovery 853 tons of black tin, or 41¼ lb. per ton of ore. The amount realized was £98,647, or £115 12s. 6d. per ton. The total receipts were £100,011, the working cost £57,853, lord's royalties £6576, and the working profit \$35,581. From the latter, £4340 was written off for depreciation of plant and buildings, and £15,526 was brought in from the previous half-year. The dividend distributed was £34,450, being at the rate of 10% for the half-year. The figures per ton treated were as follows: receipts 43s. 1d., working cost 24s. 11d., lord's dues 2s. 10d., and working profit 15s. 4d. The development work done during the half-year amounted to 2076 ft. The rich ore reported in No. 1 winze, 306 ft. east of New Sump shaft, has not proved to be continuous, for on further sinking the content fell from 80 lb. to only 20 lb. per ton. Eight of the new Holman air-cushion stamps have been in continuous operation during the half-year, and the foundations are ready for another four. The most important point, as already mentioned, is the reduction of the working cost by 4s. 5d. per ton. This is due chiefly to the advantages gained by the new Williams shaft. There is every expectation that further substantial reduction will be effected when the electrical and pumping plant is in full working order, and when the additional Holman stamps are completed.

In a recent letter I gave details of the new policy adopted with a view to reconstructing the smelting plant at the Arizona copper mine at Clifton, Arizona. The company has its headquarters in Scotland, and the new plant has been designed by L. D. Ricketts on lines similar to the plant at Cananea, over the border in Mexico. During the year ended September 30 last, 744,746 short dry tons of ore was raised, yielding 17,292 short tons of copper, or 46.4 lb. per ton. Of the ore raised, 582,335 tons of sulphide ore and 104,754 tons of oxidized ore was sent to the concentration plant. The smelter treated 153,991 tons of concentrate and raw ore, and the sulphuric acid leaching-plant 90,526 tons of oxide tailing. The revenue from the sale of copper was £866,862, and from profits of the railway and other subsidiary interests £72,827. The mining and metallurgical expenses were £625,210, and general charges for administration £29,288; £5266 was paid as debenture interest, £17,881 as income tax, £24,531 as preference dividend, £45,000 was transferred to new capital outlay, and £189,987 distributed as dividend on the ordinary shares, being at the rate of 50%. The debenture issue made for the purpose of building the new plant was sufficiently successful to warrant immediate carrying out of the plans, and orders were at once put in hand for the supply of the plant required. The whole issue was not, however, subscribed, and circulars are now being sent to shareholders with the object of placing the balance.

Gold mines in Colombia do not come often before the London public, but the Marmato Hill mine is now attracting favorable attention, after the English company owning it had passed through a preliminary stage of failure. The company was formed in February 1908 to acquire an extensive tract of country in the districts of Supia and Marmato, containing a number of gold and silver mines and prospects. Operations have been chiefly directed to the development of the Marmato Hill mine, which had yielded profits to previous local owners. The properties were examined at the time of flotation by C. Olden, L. Parker, and H. H. Knox, and subsequently, when progress was not found to be satisfactory, Arthur Wilkinson was asked to make a report. His recommendations were accepted and he was appointed consulting engineer, with T. L. Dawson as manager. Development work since has given encouraging results. Mr. Dawson gives the reserve at 109,000 tons averaging 9.8 dwt., and during the current year expects to increase the proved ore by 100,000 tons. The average content is gradually becoming higher. Recently only sufficient ore has been mined and treated to pay expenses. The construction of a new plant was delayed until the results of development warranted it. The time has now come for this work to be taken in hand, but before a final decision is made experiments are to be conducted with a view to improving the extraction by cyanide. The new plant will have a capacity of 6000 tons per month at first. Just recently 100,000 new shares of £1 were issued, bringing the total capital to £431,000. With the money thus raised £37,346 loans have been repaid, and the balance will prove ample for the construction of the plant.

CORDOVA, ALASKA

WOOD, WATER, AND FREIGHT RATES.—DEVELOPMENT COSTS.—NEW MILLS.—SOME GOOD MILL RUNS.—WORK IN THE DRIFT MINES.

Development of the quartz lodes in the Fairbanks district has been given a considerable impetus this season by the proposed legislation for a Government railroad from the coast to the Yukon and Tanana valleys. Wood is becoming scarce and a railroad which could lower the cost of freight and offer a supply of cheap fuel would materially assist in the development of the younger properties. The management at the Rhoads-Hall property at the mouth of Bed-rock creek has recently completed a well to supply water for the 5-stamp mill, but the flow at present has not been sufficient for more than one shift per day, but it is expected that a considerable supply will be available from the shaft in a short time. In the mine the ore has been blocked out so that the mill will be assured of a continuous supply as soon as the source of additional water has been determined. At the Tolovana, in the same district, a Huntington mill has been erected, and at the Newsboy, on the divide between El Dorado and Cleary, five stamps have been recently installed. The shaft at the latter property is down over 250 ft. and a contract has been let to drive a 100-ft. drift on the vein from each side of the 215-ft. level. The vein at this point is about four feet in width and seems to be approximately the same value as on the levels above where ore was developed that bore the costs of shipping to the custom mill at Fairbanks. It is generally considered that the cost of wagon and train haul plus milling charges in this district amounts to \$25 or \$30 per ton. McGillivray & Fisher, who have a lease on the Cleary extension of the Newsboy, have placed an order for a 5-stamp mill with Brumbaugh & Hamilton. The stamps will be light, weighing only 500 lb. each. The shaft is down 90 ft. on a vein which averages 2 ft. in width and is said to assay \$60 per ton.

In the drift mines winter dumps are being made on Ester, with its tributaries, Pedro, Goldstream, and Fairbanks creeks, while on the other creeks of the district work is largely confined to development for summer sluicing. 'Pay' has also been reported near the headwaters of the Salcha river, but reports from Ruby, which was filled with stampers last summer, are discouraging.

TORONTO, CANADA

PRESENT CONDITIONS AT PORCUPINE.—GOOD RESULTS AT THE DOME.—SILVER ORES IN THE KEEWATIN AT COBALT.

Thirty-seven companies and syndicates are operating at Porcupine, giving employment to about 2600 men. There are, in addition, a number engaged in prospecting and development work in outlying districts, bringing the total working force of the region up to about 3000. This number will be very largely increased with the opening of the spring. Owing to the severity of the winter several mines had to close down or greatly curtail operations on account of the scarcity of water, all the smaller water courses being frozen solid. The extension of the electric power system to many of the properties at present dependent on the scanty and unsatisfactory timber supply of the locality for fuel, will give a great stimulus to operations. Every one interested in Porcupine is looking forward to the starting of the stamp-mills on the leading properties, the date for which has been so frequently postponed, owing to unforeseen difficulties in the way of construction or delivery of machinery. These appear

HEAD-FRAME OF THE DOBIE MINE.

to have been successfully overcome and there is a reasonable prospect that several mills will be in operation within a few weeks.

The Dome mill, when in full operation, will require 250 tons of ore per day, and in order to keep this up and block out ore reserves, the number of drills employed for underground work has been increased from 12 to 24. To reserve the shafts for underground work an incline will be driven upon which to haul all ore extracted from above the 45-ft. level. At the Dome Extension a cross-cut from No. 4 shaft at the 100-ft. level has found a banded quartz vein 10 ft. wide, heavily mineralized with sulphides and carrying visible gold. A 15-in. vein of quartz assaying \$50 per ton has been found by diamond-drilling at a depth of 227 ft. At the Dome Lake the vein on the surface between 3 and 4 ft. wide has been stripped for about 1000 ft. and two shafts put down for 60 ft., at which depth samples assay \$23 per ton. Diamond-drilling to 100 ft., however, gives unsatisfactory results, showing the pay-streak diminished to one foot in width, with erratic mineralization. Work on the Success property has been resumed. The Crown Chartered Co. will complete its payments on the Davidson property and proceed with active development. Additional machinery is to be installed and the shaft sunk to the 200-ft. level. Sinking has been started on the Schumacher on the south side of Pearl lake. The property is stated to be rich in surface veins. The American Goldfields has found a 5-ft. quartz and schist vein, showing good gold content at 500 ft., by diamond-drilling. On the McNany property of the Crown Reserve a new vein has been cut which shows about 3 ft. of quartz at the 100-ft. level, fairly rich and widening out somewhat at 200 feet.

An important discovery affecting the future of Cobalt has been made at the Coniagas mine. The general belief was that silver occurred only in the diabase and conglomerate, and that the veins pinched out on reaching the Keewatin

formation. In driving on vein No. 9 of the Coniagas the Keewatin was found, but the vein proved to persist, and on being followed for 25 ft., widened to 5 in. of high-grade ore. After being opened up for 85 ft. an assay was taken which gave 2622 oz. silver. C. W. Knight, of the Provincial Bureau of Mines, has made a careful examination of the mine, and states that the formation in which the vein occurs is undoubtedly Keewatin. The Coniagas will make further explorations of portions of its territory so far supposed to be hopelessly barren. The lease of a portion of the Peterson Lake property, held by the Little Nipissing company has been canceled under a clause which provides for its termination in case of work being discontinued for one month. The property is now being operated by the Peterson Lake.

It is officially announced that the Elk Lake branch of the Temiskaming & Northern Ontario railway will start from Earlton, a point 25 miles north of Cobalt, running west for about thirty miles, the greater part of the route passing through a good agricultural district. The proposed Charlton route has been abandoned. Tenders will be called for in a few days. J. P. Whitney, the Premier, has introduced in the Ontario Legislature an important amendment to the Mining Act, which provides that no miner shall be employed underground for more than eight hours in any twenty-four hours, including the time occupied in descending and ascending from the mine. For every violation of this provision the owner and the manager or superintendent of the mine are to be liable to a fine not exceeding \$50.

NEW YORK

MORE MARKET ACTIVITY, ALTHOUGH COPPERS LAG.—BIG INTERESTS BACKING DEVELOPMENT.—COMPANY NEWS.

There has been a marked revival of activity in New York during the past week, and many operators have been trying to persuade themselves and their friends that the dark days are all past, and that the markets are once more on the way to sunshiny days of prosperity and activity. Just how far this is justified by the facts, and how much it is whistling to keep up courage, is to be seen.

The share market in copper shares lags and lags. It is quite apparent that the idea that the demand which has brought the world's visible supply to its present low figure, and American stocks to where they equal but one month's domestic deliveries, is not altogether a sound one, and that it has been aided by manipulation sticks in the mind of the public. It is one of the queer turns in the market that, barring Amalgamated and some of the leading Lake coppers that have developed rather sensationally within the past few months, the larger part of the copper list is selling lower than it was in December, notwithstanding the fact that producers and sellers of copper point to the price level of 14½¢, as firmly established.

A few months ago one would have said that a 15-cent copper market, with a surplus reduced to fair working dimensions, would solve all the problems of the copper situation. It is yet too early to tell whether or not public impressions regarding copper at the present time are correct or not. If the public's part in copper prosperity could be put in some other form besides the purchase of shares, it would perhaps be easier to interest the outsider. There is no question but that a large part of the reluctant attitude of the public is due to recent educational campaigns in reference to stock watering, and holding-company devices, and other tricks of so-called 'high finance.' There is one underlying encouraging feature in the copper situation that should not be overlooked. The heavier interests which have become more and more closely affiliated, and which are in touch with unlimited capital, are continuing to pour funds into the development of properties, and this gives evidence of every faith in the future of the copper industry.

The International S. & R. Co. has completed its plans for the erection of a refinery at East Chicago, Indiana, a suburb of Chicago, lying at the south end of Lake Michigan. The International S. & R. Co.'s business is prin-

cially copper, but the new plant is to handle lead and silver bullion, and, in a way, marks another step on the part of the Cole-Ryan interests to compete with the Guggenheims in their refining and selling of silver and lead. The new plant is to have a refining capacity of 3000 tons per month, and is to be completed by midsummer. The work is to begin immediately.

It is said that the capital stock of the Guggenheim Exploration Co. is to take a more prominent place among the big market traders. The shares have always been traded in on the New York Curb. It is now expected that the capital stock will be doubled, and the shares listed on the New York Stock Exchange, and that it will be placed on a 6% dividend basis. Among other holdings of the company is a big block of Utah Copper that is supposed to have cost \$9 per share. The Guggenheim Exploration Co. was at one time in receipt of handsome dividends from its holdings in Esperanza. Last year the company held over 60,000 shares. At the end of the last fiscal year the company had sold all but 3016 shares. It is understood that this stock has now been entirely liquidated.

A very interesting item has appeared, to the effect that E. A. Wall, of Salt Lake City, noted for his bitter fight against the present managers of the Utah Copper Co., is one of the largest individual holders of the shares of the Lake Copper Co. It is stated that Mr. Wall bought a large block of stock above 90. At the present time Lake shares are quoted around 37, and apparently are without any particular degree of support, though not offered freely, and it is seemingly impossible to accumulate any stock in the open market. Most of the present holders paid above 60, and can hardly afford to sell on the present level. The management of the Lake states that with a 14c. copper market they will in time be able to show a profit to all holders of the stock, even those who bought at the very top. Lake is still reckoned as one of the greatest possibilities of the Upper Peninsula.

While any ill effect due to increased production is minimized by copper authorities, there are, nevertheless, some new records being made. The Utah Copper Co. handled 18,300 tons of ore in one day in February, and was only prevented from making February a record month with 11,000,000 lb. output by an accident on the Denver & Rio Grande railroad. With the approach of better weather, the management is promising daily runs of 20,000 tons.

Chino shareholders are to authorize an increase in the company's capital to 100,000 shares, of which 70,000 shares are to be offered to the shareholders on a basis of 1 share for each 10 shares of new stock. The new management of the Davis-Daly has so far revamped the property as to break even in February, and hopes are entertained of making a little money in March. Financially, the company's condition has been improved by the collection of a large part of the debt owed to Davis-Daly by the Ohio Copper Co. and the collection of the cash that was invested in the property in Poreupine. The Davis-Daly market has not improved, as a loan in New York against 20,000 shares as collateral has been steadily pressing for the last month or two for liquidation.

Camp Bird shareholders in the United States have been much interested in the reports of the new discovery in the lower levels of the old property at Ouray, Colorado, but the improved conditions existing, according to these reports, have not been reflected in the market. The shares have been a little heavy in London, and most of the shareholders are now seeking information in reference to the new move of the company in taking over an interest in a copper property in Transvaal, South Africa.

The real seriousness of the situation in Mexico is beginning to be felt. The Mines Company of America, which controls properties at Minas Prietas, Sonora, and Chihuahua, is said to have complained to the Federal authorities of the confiscation of a part of its property in Mexico. The Rio Plata M. Co. has suspended dividends, and it is quite plain that all mining activity on the part of foreigners in Mexico will come to a standstill until there is a cessation of hostilities and a restoration of tranquility.

BOSTON

C. M. TURNER REVIVES CALUMET & HECLA MERGER LITIGATION.—UNITED COPPER FORFEITS CHARTER.

The irrepressible conflict between the Osceola and Calumet & Hecla interests broke out again recently when Charles M. Turner, of Houghton, Michigan, secured an injunction preventing the holding of the Osceola annual meeting on March 14. Mr. Turner is supposed to represent Godfrey M. Hyams in this move, and Mr. Hyams takes the history of the fight back to when A. S. Bigelow was president and brought suit against Calumet & Hecla to prevent it absorbing the control of Osceola. Mr. Hyams was associated with Mr. Bigelow in that fight. Calumet & Hecla bought out Mr. Bigelow's interest in Osceola and other Lake properties and the latter retired from the field. His mantle seems to have fallen upon Hyams, who last year with other interests was successful in blocking the Calumet & Hecla proposed merger. The present injunction is a repetition and scarcely in any sense a variation of the old Osceola fight against Calumet & Hecla. It is charged that the larger company, seeing extinction of its ore reserves in the not distant future, is anxious to absorb the Osceola and wipe out its identity as an independent company, the move being made to recruit the Calumet's ore reserves. When the Bigelow régime went out, Mr. Agassiz, vice-president of Calumet & Hecla, succeeded him as president, and Quincy A. Shaw, president of the Calumet, became the Osceola's vice-president. The Calumet people disclaim the alleged designs on Osceola, though the company and its associate interests are in control. The Calumet & Hecla company has been benevolent in its assimilation policy in the Lake—so much so that its acquisitions there have not been viewed with especial alarm. Something over a year ago the company engaged J. Parke Channing to make an examination and appraisal of the properties which it intended to include in its big merger. It was said afterward that Mr. Channing was retained for this purpose because, of course, of his high character and ability as an authority, and because of the mental reservation that he was associated with the Lewisohns and was considered close to Amalgamated interests, the latter being brought into the original suit of Bigelow in behalf of Osceola against Calumet & Hecla. The Calumet & Hecla company would undoubtedly conserve the copper resources of the Lake country by extending its control, but the Osceola protesting minority interests set forth in their case that it proposes to violate the Sherman anti-trust law by restraining trade.

The United Copper Co. forfeited its charter in New Jersey a few days ago because of the non-payment of taxes. This is the ambitious holding corporation which F. Augustus Heinze formed as a rival to Amalgamated. Mr. Heinze states that the non-payment of taxes was a clerical oversight and that the present charter will not be allowed to go by default. United Copper is said to have largely precipitated the panic in October 1907. The company owns 300,000 acres of timber land in British Columbia and the control of a number of copper companies.

A special meeting of the stockholders of the Chino Copper Co. will be held April 2 to authorize an increase of the company's authorized capital stock from 800,000 to 900,000 shares, par value \$5. Of the new 100,000 shares, 70,000 shares have been underwritten and will be offered for subscription at \$25, stockholders being entitled to subscribe *pro rata* on the basis of one share for each ten shares already held.

The Calumet & Hecla company issued simultaneously, on March 11, a bunch of reports on Isle Royale, Superior, Tamarack, Allouez, and Centennial, which are under its management. Calumet & Hecla is working hard to bring about a realignment of milling facilities affecting these properties and to operate them as a whole in the interest of economy and increased output.

The settlement of the Lawrence woolen mill strike will be a great help to market interests in Boston and New England. The direct financial loss is estimated at \$3,000,000 at least.

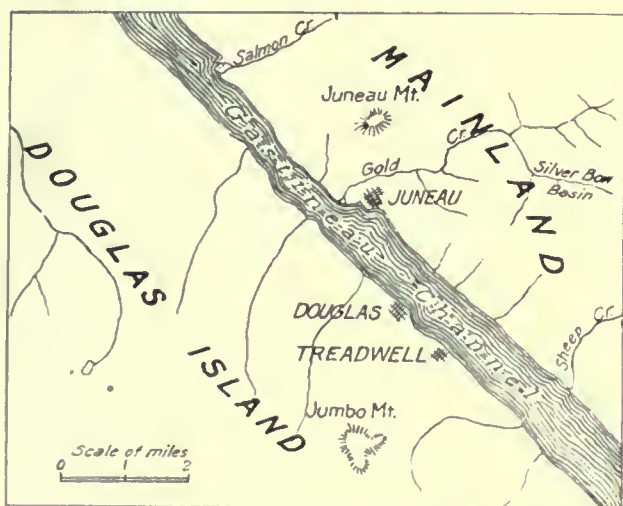

General Mining News

ALASKA

JUNEAU

The Alaska Mexican Gold M. Co. in January crushed 19,803 tons of ore, from which 474 tons of concentrate was saved. The realizable value of the total production was estimated at \$65,802, including the gold production of \$31,008. Operating expenses were \$31,365 and construction expenses \$3087, leaving an estimated net profit of \$31,350. The yield per ton was \$3.36. During the month 290 ft. of development work was done.

The Alaska United G. M. Co. in January produced, 'realizable value,' \$42,735 from the Ready Bullion claim, and \$46,338 from the 700 Foot Claim. Operating expenses amounted to \$28,420 for the Ready Bullion and \$29,629 for the 700 Foot Claim. Construction expenses were \$1469 and \$2508, respectively, the estimated net profit being \$12,346 for the Ready Bullion and \$14,202 for the 700 Foot Claim. The ore treated at the Ready Bullion amounted to 18,808 tons, and at the 700 Foot Claim to 20,266 tons.

PART OF DOUGLAS ISLAND.

Development work for the month amounted to 32 ft. and 365 ft. for the respective claims.

PRINCE WILLIAM SOUND

Rich ore was discovered recently on the 400-ft. level of the Cliff mine, says a Valdez report. The Midas Copper Co., according to a late report, has 100 tons of ore ready for shipment to the Tacoma smelter.

THE TANANA

A report from Fairbanks states that Utegaard & Nehrland, lessees on the Pioneer property on Chatham creek, have shipped to the Garden Island mill 60 sacks of picked ore estimated to average about \$90 per ton. After this ore is disposed of, the mill will start on four tons of ore from the Anderson & Birch property in Granite gulch, near Pedro creek. The mill has just finished treating 12½ tons from L. J. McCarty's Pennsylvania claim on Wolf creek. Mr. McCarty stated that if better milling facilities were provided for that district, outside capital would not be required for developing the properties.

L. M. Drury, assayer, of Fairbanks, has received \$209 for a shipment of 1234 lb. of placer tin ore obtained from the Hot Springs district. The ore was brought to Fairbanks by Joseph Eglar. There the schist and other impurities were removed. The ore was exhibited at the New York land show and was shipped to England, where assays gave returns of 55.49% tin, 4% sulphur, and a small amount of arsenic. Freight, portage, and other charges for the ocean shipment amounted to \$73, leaving a net balance of \$208. Faleon-Joslin, who had charge of the ore, has stated that the A. S. & R. Co. is willing to build a smelter at Tacoma for tin ore if the ore deposits

are sufficiently large to justify continuous operation of the proposed smelter. Paul Hopkins intends soon to concentrate a large amount of ore from the district for shipment to Europe.

ARIZONA

COCHISE COUNTY

The Shattuck-Arizona Copper Co. has intersected ore assaying 41% copper and 34 oz. silver per ton in No. 9 cross-cut of the Shattuck mine at Bisbee, according to a report by Thomas Bardon, president of the company.

PINAL COUNTY

The U. S. Geological Survey has issued a topographic map of the Ray, or Mineral Creek, district, for which the topographic surveying was done by W. M. Beaman. The map is on the scale of 1:12,000, or more than five inches to the mile. The contour interval is 25 ft. Every topographic feature, as well as buildings, shafts, and adits, is shown. The maps are for sale by the Geological Survey at 5c. each or \$3 per 100.

The Ray Con. Copper Co.'s actual January production, for which previous estimates have been published, was 2,476,944 lb. copper, as against 2,271,654 lb. in December. The production would have been larger had it not been for the blowing out of a motor. Since operation was started March 20, 1911, the company has produced 17,602,642 lb. copper. Since February 20 the concentrate has been shipped to the A. S. & R. Co.'s smelter at Hayden. It is officially announced that the cost of production is under 9c. per pound, but more exact figures are not obtainable. The monthly production of the company since last April has been as follows, the figures being for pounds:

April	704,261	October	2,069,287
May	1,006,922	November	2,507,000
June	1,167,463	December	2,271,654
July	1,689,124	January	2,476,944
August	1,833,083		
September	1,876,904	Total	17,602,642

YAVAPAI COUNTY

In Prescott, gravel reported by Mr. Robinson, city clerk, to assay 30c. per cubic yard has been used in street paving. The gravel will be used for the same purpose in the future, says a press report, unless some economical means of saving the gold is proposed.

Rumors from Prescott are to the effect that the management of the Climax property is planning to erect a plant for treating its ores and to obtain electrical equipment for the mine. The Bradshaw M. & S. Co. has been incorporated to develop the Nellis and Cleator groups of claims near Turkey. It is reported that Los Angeles investors back of the company plan operation on a large scale. The property recently was examined by Joseph Reese. The Tip Top-Heath M. Co. has secured a Denver roller mill for the Tip Top mine in the Bradshaw district, and on its erection will start treating ore on the dump.

CALIFORNIA

KERN COUNTY

Sidney Coburn, of Los Angeles, has secured an option on claims adjoining the Baltic property, where a valuable vein recently was found, says a Randsburg report. The shaft of the Good Hope, operated by the Consolidated Mines Co., is down 190 ft., and the vein persists in depth. A night shift will be added. A mill-run finished a few days ago yielded \$3450. The Four Ace M. Co. has discovered unusually rich ore on its property.

Joseph Weringer, owner of the Greenback copper mine at Woody, is planning to organize a company to operate the property, which, with intermittent development, has in the last 22 years produced about \$40,000, according to newspaper estimates. About \$60,000 has been spent on the mine. There is 200 tons of ore on the dump.

MOBAC COUNTY

(Special Correspondence).—Deep snow covers the ground at the new district of High Grade, and little mining is

going on. Several companies are arranging for work as soon as weather conditions permit. At the Sunshine claim a streak of quartz and tale 10 to 12 in. wide is receiving attention. Miners recently coming in from High Grade state the Sunshine has a shipment of 800 sacks of rich ore about ready for treatment. Some of this assays about \$1000 per ton. It is stated that N. E. Guyot has taken a lease on the Old Glory claim of the Fort Bidwell Con. group. In the Mountain View claim of this group rich ore is being taken from a seam about 8 in. wide. It is reported the Gold Peak and Klondike claims, adjoining the Fort Bidwell Con. estate, have been acquired by Denver people. It is understood the new interests will operate them under the name of the High Grade Gold Mines Co. The Modoc Mines Co. is sinking its shaft with hand power and is planning to buy a gasoline hoist. Chicago people are interested in this company. Every indication points to a rush into the district as soon as spring has set in, but it is doubtful if active development can be started before June. Several engineers from Denver, Salt Lake, Spokane, and other points have recently visited the district.

Fort Bidwell, March 15.

NEVADA COUNTY

High-grade ore has been discovered on the Mizpah claim, located last fall by W. S. Gregory and John Lew.

TUOLUMNE COUNTY

The Humbug adit, Table mountain, near Jamestown, has been drained, and ore assaying \$8 to \$60 per ton is being mined.

The Melones M. Co., according to a report from Jamestown, which for years has operated one of the principal low-grade properties in the state, situated near the old Robinson ferry, has discovered ore assaying about \$4000 per ton. Ten tons of the high-grade ore has been taken out, and the size of the vein, or possibly pocket, is not known. Some years ago a similar pocket of rich telluride ore was found, which assayed \$28,000 per ton, and three-fourths of a ton of this was obtained.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—There is great activity at the Newhouse adit, a force of 200 men going to work through that bore. The principal work is being performed on the Gem, Saratoga, King Bee, and Dyke mines. On the Gem mine Von Tilborg & White are shipping from 50 to 60 tons of mill ore per day, and inside of 30 days the output will be doubled. Stoping has been started on a body of ore that is from 3 to 8 ft. wide. E. F. Fitzgerald has purchased the Octopus group of claims on Chicago creek from Texas owners. Development will be carried forward through the United States adit. Operations will be put under way March 1 at the P. T. mine on Chicago creek. H. B. Baker is manager.

Idaho Springs, March 13.

MINERAL COUNTY

A topographic map of the Creede, or Sunnyside, district has been issued by the U. S. Geological Survey. The topographic surveying was done by R. H. Reinecke, under the direction of R. B. Marshall, chief geographer. The scale of the map is 1:24,000, or more than two and one-half inches to the mile, with a contour interval of 50 ft. The altitudes range from 9000 to 12,000 ft. above sea-level. In 1910 the district produced 62,956 tons of ore, valued at \$1,036,286, of which \$121,181 was in gold, \$417,810 in silver, \$3687 in copper, \$362,824 in lead, and \$130,784 in zinc. There were 9 producing mines in the district in 1910. The new maps are for sale by the Geological Survey at 5c. each or \$3 per 100.

OURAY COUNTY

It is reported that operation will be resumed at once in the Revenue mine. Plans are being made for reorganizing the Red Mountain M. Co. If reorganization is

effected, development is to be resumed on the property during the coming summer.

SAN MIGUEL COUNTY

Newspaper despatches state that four men were killed March 14 by a snowslide which swept away the mine buildings at the Black Bear property.

TELLER COUNTY (CRIPPLE CREEK)

A late Cripple Creek report states that, according to the figures of T. R. Countryman, engineer in charge of the Roosevelt drainage adit, the flow is only 16,000 gal. per minute, as against 17,500 gal. the previous week. It is thought the reduction is due to clogging of the new water-course. A measuring weir probably will be constructed at once.

The New Pearl M. Co. is preparing to resume operation on its Mineral hill property. The Kittie M. property, on Gold hill, is ready to resume shipment. E. Riley and associates, lessees on block 16 of the El Paso Con. G. M. Co. estate on Beacon hill, recently discovered a rich new ore-shoot.

The Mary McKinney M. Co. is reported to be considering paying dividends at the rate of 3c. per share per quarter on the 1,309,252 shares issued. In February the company shipped seven cars of ore averaging \$25 per ton. Lessees produced 18 cars of ore. Oscar Fogleman of Cripple Creek is planning to start the Old Gold mine in the near future. The regular meeting of the Jerry Johnson company will be held in August, instead of this month. The Gould M. Co. has been reorganized under the name of the Kitty Lane Gold M. Co. The corporation has acquired the Rhinoceros, Nil Desperandum, Kitty Lane, and Sitting Bull No. 1 and 2 claims. Sinking of the main Elkon shaft has been resumed.

It is rumored that the Portland mill at Victor will be increased to a capacity of 500 tons per day. There are ten agitation tanks in the mill, the last being added only a few weeks ago. There are 31 concentrating tables, an increase of 8 since the first 300-ton unit was put in operation. Thomas Crowe, superintendent for the company, has predicted that in March 14,000 tons of ore would be treated in the mill.

A report from Cripple Creek states that an electric hoist has been erected at the Cresson No. 2 shaft. The Blue Bird mine, Bull hill, in February shipped 20 cars of ore averaging about \$30 per ton.

IDAHO

* IDAHO COUNTY

W. A. Edwards, manager for the Eagle M. Co. of Edwardsburg, has completed arrangements for the construction of a hydro-electric power and lighting system for the property.

SHOSHONE COUNTY

Reports from Wallace state that the first payment on the Alice mine, near Mullan, has been made by Eastern holders, and it is announced that operation will be resumed in a short time. The mine has been closed about a year, but pumps have been operating for several weeks, and the lower levels are now almost clear. The Bunker Hill & Sullivan M. & C. Co. has paid dividend No. 174, amounting to \$49,050, for March. This makes the total amount of dividends paid \$13,339,500. H. F. Samuels, manager for the Success M. Co., operating on Nine Mile, in the Wallace district, announces the directors have declared a dividend of \$15,000, payable March 20. This dividend will be at the rate of 1c. per share.

W. A. Clark will expend \$100,000 in the development of a group of claims on Sunset peak, north of Wallace, according to a Spokane report. Additional men will be put on as soon as weather permits. A winze is being sunk on the main vein.

MISSOURI

JASPER COUNTY

The once-famous Pumpkin Head mill, operated by the Chicago-Joplin Mining Co., west of Joplin, has been moved

to the lease of the Rich-in-Ore Mining Co. at the new district of Thoms Station. In opening this mine, a rich pocket of blende assaying better than 20% was opened, but was quickly worked out. Subsequent development revealed good ore, and the ground was opened sufficiently to warrant the erection of a mill. North of the Rich-in-Ore is the new mill of the Great Western Mining Co., which began running the latter part of February. The plant is entirely new, including framework and machinery. The ground has been opened. Also, a number of drill-holes have been sunk into ore-bearing dirt. Natural gas, supplied to the district from fields in southern Kansas and northern Oklahoma, has been so low during the cold weather of the winter that orders to discontinue its use beneath boilers were issued. Fuel oil is being substituted in many instances.

MONTANA

JEFFERSON COUNTY

The Grand View M. & D. Co., operating a group of nine claims in Goodrich gulch, 20 miles south of Whitehall and 10 miles east of Twin Bridges, reports that more than 1000 ft. of development work has been done, the No. 2 adit cutting the lodes at depth varying from 200 to 400 ft. The No. 3 adit is nearing the ore.

PARK COUNTY

F. C. Byrne, while in Spokane a few days ago, said that the Cooke district has some of the best mineral land in the state. Sulphide ores taken from near the surface average 12% copper. On account of lack of railroad facilities it has been impossible to interest capital in the development of the properties. It is thought probable the district will receive connections from either the Northern Pacific or the C. M. & St. P. in the near future.

LINCOLN COUNTY

(Special Correspondence.)—W. E. Williams and A. J. Williams have given a bond on the Mountain View group of claims to W. H. Graham of San Francisco for \$90,000, and according to the terms of the contract, work must start within 60 days. The claims are at the head of Silver Butte creek, near the boundary line between Sanders and Lincoln counties, and are well known in this district because of the many rich specimens of ore that they have produced.

Libby, March 15.

SANDERS COUNTY

J. C. Williams and Thomas Pendergrass and associates, says a report from Spokane, have located a group of five claims known as the Dustin group, and have found ore in the adit assaying \$30 to \$80 copper per ton. An adit has been driven into the hill 50 ft. and is now in good ore. In addition to the copper, the ore is reported to average about \$8 gold, with some silver.

SILVERBOW COUNTY

A new orebody has been opened on the 1600-ft. level of the Butte-Ballaklava mine. The Corbin Copper King M. Co. has taken over the property of the Montana Corbin Copper Co. and expects to start operation some time next month. A property which mining men predict will be in the producing class before the year closes is the Pilot Butte. The annual meeting of the company was held a few days ago. Edward Hickey was elected president; William P. John, vice-president; John W. Pratt, treasurer; and Jerry J. Harrington, secretary. The shaft is down 900 ft. and development work is being carried on with encouraging results.

NEVADA

CLARK COUNTY

The Quartette M. Co., of Searchlight, has leased its accumulation of tailing to C. H. Jonas, who will add a slime-treatment department to the 150-ton leaching plant on the property. The enlarged plant will be in operation by the middle of April.

ESMERALDA COUNTY

Plans are under way for the reorganization of the Blue Bull and Booth companies on the assessable stock plan. A.

H. Lowe, secretary of both companies, has mailed letters to the stockholders telling of the proposed action.

The Commercial Association of Goldfield on March 16 decided to undertake reviving interest in the Goldfield mining stock exchange. Resolutions were passed protesting against the closing or suspension of the San Francisco mint.

HUMBOLDT COUNTY

(Special Correspondence.)—The Seven Troughs Coalition Co. is completing its cyanide plant and shortly will commence treatment of a large quantity of stored tailing. The plant will handle about 30 tons per day. The Friedman winze from the 10th level of the shaft is going down on a 6-in. shoot of rich ore. Between the 9th and 10th levels a 6-in. shoot of rich ore is being stoped. Portions of this assay over \$200 per ton. National advices report the production of 100 sacks of bonanza quartz from a pocket in the vein of the National Mines Co. Some of the ore is said to have assayed \$9000 per sack. A strong vein of gold-bearing ore is being opened in the Shively group, on the north slope of Winnemucca mountain. In places the vein shows a width of 18 ft., assaying on the average \$8 per ton. The shaft has been sunk 30 ft. The mine is about five miles from this city.

Winnemucca, March 16.

G. O. Cole, a lessee on the Industry property, is reported to have recently discovered a stringer of hornsilver. This is the first discovery of hornsilver in the district, and is said to be one of the richest silver finds in its history. The Pompeii M. Co. has resumed operation on its property, near Searchlight, with John R. Mendenhall as superintendent. It is stated that after some prospecting work is done it is probable that a double-compartment shaft to tap the orebody at depth will be sunk.

The Comet Placer M. Co. has secured machinery for the development of its property near Sulphur, a station on the Western Pacific railroad. L. G. Burton, of Salt Lake City, is in charge of the property, which consists of 3520 acres of land.

LYON COUNTY

Reports from Salt Lake City state that the second furnace of the Mason Valley smelter will not be blown in for two or three months. The first furnace, with a capacity of about 700 tons per day, is treating all the ore now being shipped.

George W. Knierim, of Yerington, has discovered on his Rescue claim, south of Yerington, a 10-ft. vein of bluish gray quartz resembling the Tonopah ores. The vein was found at a depth of 135 ft. A carload of ore will be shipped shortly to the smelter at Thompson.

The Mason Valley Mines Co.'s report for the year ended December 31 shows that 2268 ft. of development work was done during 1911. The main adit-level was equipped with an electric mine railroad, a crushing plant was erected, and an aerial tram 6250 ft. long and with a capacity of 100 tons per hour was built. Construction was completed during the year for the smelter, of which the first furnace was blown in January 6. Assets, December 31, 1911, amounted to \$229,035, including \$117,988 cash on hand. Liabilities were \$147,449, leaving an excess of assets of \$81,586.

NYE COUNTY

Charles Kirchen, manager of the Associated mill now being built at Manhattan, has announced that the plant should be ready for operation on schedule time, April 1. The adit of the Mineral Hill Con. is in over 600 ft., but it will take some time to reach the ore-shoot from which rich ore was taken on the surface last summer. The Manhattan M. & M. Co. is driving to intersect at depth a shoot from which last summer ore assaying \$12 to \$20 per ton was taken at the surface. Tarash, Glavnick & Varos are sinking a winze on a promising streak of ore on the Dexter 14 property, adjoining the Big Four property. On the Big Four property the Peak-Steen-Cieala lease is producing about 100 tons of ore per day, the ore averaging between \$20 and \$25 per ton.

The Tonopah Mining Co. in February made a net profit of \$147,933, according to the regular report

just issued. The company treated 14,326 tons of ore which averaged \$19.45 per ton. The gold and silver bullion shipped during the month amounted to 255,110 oz., and was valued at \$202,807. During the month 86 tons of concentrate was shipped. The concentrate was valued at \$45,826. The company has declared the regular quarterly dividend of 25c. per share and an extra dividend of 15c. per share, both payable April 20 to stockholders of record March 30.

The production of the Tonopah district for the week ended March 16 was 8870 tons of ore, valued at \$221,750. The Tonopah Mining Co. led the list of producers with 3450 tons. The Tonopah Belmont reports cutting a new vein in a cross-cut on the 12th level of the mine.

STOREY COUNTY

J. D. Moore, E. G. Hummel, and T. J. Meagher, all of Virginia City, have incorporated the Clermont Con. Gold & Silver M. Co., under the Nevada laws. The company will take over the Clermont, Clermont No. 1, Clermont No. 2, and Clermont Fraction claims in the Flowery district, east of the Comstock. The Ophir company last week shipped a car-load of concentrate, valued at \$25,000, to the Selby smelter. The first shipment of pumps for the C. & C. shaft has been received at the property.

The Ophir company last week produced 222 tons of ore, valued at \$8050. During the week 325 tons of second-class ore was shipped to the Kinkead mill. The Con. Virginia 3-compartment raise was carried 7 ft. during the week, and now is 16 ft. in length. In this work 67 cars of ore, valued at \$1903, was saved. While work in the Crown Point was hampered through trouble with the motor for the Yellow Jacket hoist, about 380 cars of ore was mined, and 370 tons of ore was shipped. The Pumping Association reported last Saturday that the water was at the 2500-ft. level. Customary development was done in other Comstock properties. The Yellow Jacket mill ran on dump ore.

WHITE PINE COUNTY

Pumping will be started shortly in the Giroux company's Bunker Hill shaft, which now is 210 ft. deep. The Bunker Hill is close to the Butte & Ely property line, and it is thought that development there will serve to prospect in a measure that property.

NEW MEXICO

GRANT COUNTY

Twenty-one cars of ore was shipped last week from Lordsburg. The Apache Box mine is shipping ore, protected by armed men from 'high-graders', to the Clear Lake mill. Transportation is by burro.

The buildings for the fourth and fifth units of the Chino Copper Co.'s mill are practically completed, according to a statement by D. C. Jackling, general manager for the company. The company in February kept costs at about 7c. per pound. The mill averaged 1100 tons per day per unit for the month. The third unit will be put in commission by the end of the month. As the ore came from close to the surface, the recovery was not as large as otherwise would have been the case.

SOCORRO COUNTY

(Special Correspondence.)—The last bullion clean-up for February of the Ernestine M. Co. resulted in 6785 oz.; concentrate for the same period, 7000 lb. The total output for the month was 24,825 oz. gold and silver bullion and 15 tons concentrate. Much local interest is manifested in the proposed railroad route from Silver City to the Mogollons and north to the coalfields. Should the plan be carried out, the severest handicap of this district would be lifted, as the costly 90-mile wagon haul has been a barrier to the economical operation of many properties.

Mogollon, March 19.

OKLAHOMA

HASKELL COUNTY

Eighty-seven men were killed in an explosion at the San Bois M. Co.'s mine No. 2 on March 20. The mine had been closed a week for repairs to the boilers in the engine-house, and the explosion is attributed to supposed accumulation of gas in the workings. The state mine inspector, with rescue apparatus, is at the property.

UTAH

JUAB COUNTY (TINTIC DISTRICT)

During February the Chief Con. mine produced about 2250 tons of ore. The net profit for the month is estimated at \$56,000. One car shipped during the month brought a return of \$10,777. The previous richest car was valued at about \$8000. For the 25 working days of February the Iron Blossom averaged a production of about 360 tons of

MINE RESCUE CAR.

ore per day. Last week 172 cars of ore was shipped from the district.

SALT LAKE COUNTY

The Ohio Copper Co. in February earned \$37,500, the largest amount since the new mill was started. The tonnage of ore treated was about the same as usual, but the ore was of higher grade, and a reduction in costs was effected.

SUMMIT COUNTY

The report of the Daly-Judge M. Co. for the year ended December 31 shows that the mill in that period treated 51,875 tons of ore, from which 12,237 tons of lead concentrate and 3919 tons of zinc middling were obtained. The company started the year with an available balance of \$316,215, and closed it, after paying the dividend, with \$431,120, showing a gain of \$115,405. The surplus earned in interest \$18,838; more than enough to pay drainage expenses. The Ontario drainage adit is so far advanced that cross-cutting may be started on the 2500-ft. level whenever desired.

TOOELE COUNTY

The first annual report of the Lion Hill Consolidated, from organization to December 31, 1911, shows total receipts of \$44,653, of which \$13,738 was from sales of ore and \$30,915 from the underwriters. Expenses included \$42,663 at the mine and \$1941 general expense, a total of \$44,604. Development work done amounts to 1859 feet.

WASHINGTON

FERRY COUNTY

The Anaconda Gold M. & R. Co., of Spokane, has been organized by Arthur L. Flagg, G. A. Collins, G. S. Bailey, George Kebel, and N. D. Walling. The capitalization is \$2,000,000. The company has a bond on, and has made the first payment on the Ida, Lucky Fraction, Ruby, Last Shot, First Thought, Josephine, and Minnie claims, between Quilp and the old Republic mines in the Republic district.

CANADA

BRITISH COLUMBIA

Seven men were killed and two injured in an explosion March 7 in the Diamond Vale colliery. The cause of the explosion is thought to have been the ignition of a pocket of gas by a naked light.

ONTARIO

The Nipissing company's production for February is estimated at \$226,419, net value. During the month 578,943 oz. of silver was shipped.

A report from Elk Lake states that the owners of the Donaldson claim have purchased a new plant, brought to the district by the Diabase M. Co. The Donaldson shaft is down over 100 feet.

The Nova Scotia mill is temporarily closed, in order that repairs and additions may be made to the concentrating department. What is said to be the richest shipment ever made from the Montreal river district was recently sent out by the Mann mine, at Gowganda. The 15 tons of ore was valued at \$40,000. The City of Cobalt M. Co., which has a lease on the King Edward mill, is erecting in the mill four new Deister and James tables.

The first annual report of the Northern Ontario Exploration Co., managed by the Bewick-Moreing company, shows a gross profit since the company was organized in January 1911 of £81,481. The directors have written off £40,000 from the cost price of the shares, as only a limited amount of development work has been done. The assets include cash on hand and receivable, £101,000, and other assets acquired at a cost of £103,000. The capital issued amounts to £119,000. The whole balance of profit is to be carried forward for important developments in Alaska and other places.

Recently organized mining companies in Ontario include the Porcupine Golden Quill M. Co., Ltd., capitalized at \$1,500,000, with headquarters at Toronto; the South Bay Mines, of Gowganda, capitalized at \$40,000, with headquarters at Toronto; the Lake Superior Basin M. Co., capitalized at \$1,000,000, with headquarters at Fort Erie; the Kenroy Gold Mines, \$1,000,000 capitalization; the W. S. M. K. Mining Co., \$200,000 capitalization; the Porcupine Twins M. Co., capitalized at \$1,950,000; the Ungava Exploration Co., Toronto, \$1,000,000; the Dane M. Co., Haileybury, \$500,000; and the Huronian Exploration Co., New Liskeard, \$50,000.

YUKON

Recent reports from Sixtymile state that 40 holes have been sunk there, but that only 'Lone Swede' Matson, the original discoverer, has found pay-ore up to the present time. Over 50 men are said to be working along the creek and to be preparing for a long stay there. J. E. Barrett has reported in Cordova the discovery of large areas of bituminous coal at the head of White river, on the Canadian border.

MEXICO

OAXACA

(Special Correspondence.)—The Cubilete company, in the Taviche district, has just placed its order for a 150-ton cyanidation mill with the Fraser & Chalmers Co. of London, and excavation will be started immediately in an effort to have the mill ready by October 1. This will be the first mill in the Taviche district, and the first modern cyanidation mill in the state. The machinery will include 1500-lb. stamps of the South African type, tube-mills, Patterson tanks, Oliver filter, and zinc-dust precipitation. Tables for concentration when required will be provided for. The district is producing now about \$100,000 of shipping ore per week. The San Juan and San Martin properties will break ground shortly for cyanidation mills, and on the completion of the same the general district will be producing over \$1,000,000 per month of silver and gold. Henry Valle is manager for the Cubilete company, and the consulting engineer is P. A. Babb.

Oaxaca, March 18.

Among the Copper Mines

The QUINCY MINING Co.'s annual report will show a surplus, above the \$4 dividends paid, of \$60,000 for the year, on an average selling price of copper for the year of 12¾¢. The \$150,000 paid for new properties by Quincy in 1911 was taken out of surplus.

TENNESSEE COPPER produced 13,808,940 lb. of copper during 1911, from its own ores, as compared with 12,429,009 lb. in 1910. From customs ores there was produced 3,832,972 lb., against 4,147,326 in the previous year. The total production of the Tennessee plant was 17,641,982 lb., compared with 16,576,335 lb. in 1910. With the exception of 1909, the Tennessee's yield from its own ores was the largest on record.—*Boston Commercial*.

The LAKE COPPER Co. has begun preliminary shipments from its stock pile to the Trimountain mill. These shipments are being made in order to get the ore out of the way and make room for additional trackage necessary for regular production, which is expected to begin in June. Lake now has one of the most conservative of mining managements, and if the early hopes regarding the property, which sent the stock up from \$4 to \$94¼ per share, are realized it may yet prove to be one of the best in the Lake Superior district.

The COPPER PRODUCERS' report for April will show probably some increase in stocks, as refinery outputs will be somewhat larger and exports will be materially curtailed. The English coal strike, which has extended to Germany, intervenes at a time when the onward and upward march of the metal is checked. Before the coal strike situation became acute, 15-cent copper seemed probable at an early day. Now the prospect is much farther away. However, if the statistics and estimates given out by the Producers are correct, the metal situation was approaching a crisis, and the foreign disturbances may have come just at the time to prevent a congestion which might have resulted in much higher prices.

The BRITISH COLUMBIA COPPER Co. in January produced 558,190 lb. copper, as against 250,717 lb. in December. In precious metals, the production was 1746 oz. gold and 8405 oz. silver in January, as against 1216 oz. gold and 3811 oz. silver in December. Last year, owing to the miners' strike, only one furnace was kept in operation. On February 12 the full battery of three furnaces was blown in. At a depth of 100 ft. in the Voight property, on which the company secured an option last year, a cross-cut intersected an 8-ft. vein assaying as high as 8% copper and \$11 gold per ton. The company has driven 105 ft. on the vein, and it is believed that the ore will persist in depth. The ore from the British Columbia property is reported to average 1¼% copper and \$1.10 gold per ton. The net profit for February is reported to be \$36,500.

EUROPEAN STOCKS have decreased 4238 tons, and the visible supply 5600 tons, says the James Lewis & Son's report issued March 1. Shipments of refined copper from the United States to Europe continued on a large scale, 31,643 tons being taken from the northern ports, showing enormous consumption. Germany's consumption for the month was 17,648 tons, an increase of 6258 tons over that for February 1911. American wire bars have been sold at £66 15s. net c.i.f. for April shipment. The imports for the month were 23 tons and the deliveries 4239 tons greater than for the same month last year. Total arrivals in England and France amounted to 19,734 tons and deliveries 22,372 tons. Arrivals in England from Chile reached 1174 tons and deliveries 1239 tons. From other countries the figures were 10,096 and 13,157 tons, respectively. Arrivals in Liverpool and Swansea from the United States amounted to 3362 tons; in London, 1000 tons; and in France, 8064 tons.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

JOHN ROSS, JR., is here.
D. W. SHANKS is in town.
F. L. SIZER has gone to Arizona.
C. COLCOCK JONES is in Montana.
E. C. B. HEDEN is now at Sydney.
M. H. KURLYA is in San Francisco.
C. B. LAKENAN is in San Francisco.
THEO. J. HOOVER is at Broken Hill.
STEWART RAWLINGS is in San Francisco.
J. E. SPURR is on his way to Philadelphia.
WALTER HARVEY WEED has been in Cananea.
D'ARCY WEATHERBE has gone to Vladivostok.
ERNST LICHTENBERG is at Halifax, Nova Scotia.
A. P. WILSON expects to leave for Alaska shortly.
EDMUND JUESSEN was at Grass Valley last week.
W. J. LORING has returned to London from Burma.
MALCOLM MACLAREN has returned to San Francisco.
EDWARD M. RABB is confined to his bed by appendicitis.
T. G. PATTON and J. W. SHANKLIN are here from Placer-ville.

T. E. EVERHEART has gone to San Juan, Argentine Republic.

J. FORDYCE BALFOUR has gone to Naraguta, Northern Nigeria.

W. T. FARNHAM, of the Chicksan Mining Co. is in San Francisco.

HUXLEY ST. JOHN BROOKS is returning to London from the Philippines.

WILLIAM H. BLATCHLEY is now with the La Blanca y Anexas at Pachuca.

C. R. EASTMAN is chairman of the department of geology of the University of Pittsburg.

THOMAS J. LAWRENCE, manager for the Topia M. Co. of Durango, Mexico, is at Los Angeles.

C. S. HERZIG has gone to Nigeria. His permanent address is 419 Salisbury House, London, E.C.

C. S. HALEY is assistant superintendent at the Nash mine, Carrville, Trinity county, California.

HOWLAND BANCROFT is at Los Angeles and will go to Arizona, returning to Denver by April 1.

C. W. PURINGTON has terminated his connection with the Orsk Goldfields, Ltd., and is now in London.

EDGAR A. COLLINS will return from Africa shortly to take charge of the Commonwealth mine in Arizona.

TRACEY BARTHOLOMEW, formerly connected with the Nevada Consolidated Mining Co., has gone to Porto Rico.

A. W. GEIGER has returned from Colorado and sailed, March 21, for the Philippine Islands to examine the Major properties.

L. K. FLETCHER has charge of construction work upon a new mill at Pozos, Guanajuato, and is no longer connected with the Rincon mine.

GEORGE A. SCHROTER was at Los Angeles this week on his way to the Creston Colorado mine, returning from Dolores and El Rayo.

RALPH HOOVER, of the Dow-Willans Diesel Engine Co., has left San Francisco for London, where he will investigate factory and engineering practice with reference to the Diesel engine.

T. A. RICKARD will speak before the Mining Association of the University of California on Wednesday, March 27, at 8 p.m., in the Hearst Mining building.

The San Francisco section of the MINING AND METALLURGICAL SOCIETY OF AMERICA will meet on Monday, April 1, at the Palace hotel at 6:30 p.m.

Bullion Tax List, Nevada Mines

The laws of Nevada require that sworn quarterly statements be submitted by operating companies to the state bullion tax collector. The table given below shows the re-

ports of the principal companies for the quarter ended September 30, 1911. The information is in some cases somewhat misleading, as the column 'expenses' comprises all expenditures on company account during the period under review, regardless of whether such payments are operating expenses or capital expenditure.

Mine.	Tons.	Total value.	Expenses.	Taxes.
Nevada Hills	1,138	\$31,625.29	\$47,876.62	None

GOLDFIELDS were recently discovered, according to a Renner's report from Nikolaievsk, in the basin of the Lamur, a small tributary of the Amur, which at first were secretly worked by 300 Russians, Chinese, and Koreans. At present there are three gold-prospecting parties in the fields, representing various companies, who have reported further

finds. A large number of gold finds have also been made on the right bank of the Lower Amur.

THE Bunker Hill & Sullivan Mining & Concentrating Co. paid dividend No. 174, on March 4, 1912, of \$49,050. This makes the total amount of dividends paid \$13,339,500.

Company Reports

VAN-ROI MINING CO., LTD.

This company was formed in 1908, as a subsidiary of the Le Roi No. 2, Ltd., to acquire the Vancouver group of silver-lead-zinc properties in the Slocan district of British Columbia, and has a capital of £34,500, in 30,000 preferred shares of £1 each, and 90,000 ordinary shares of 1s. each, of which 60,000 are held by the Le Roi No. 2. The report is for the year ended September 30, 1911, but the mill was only in operation half that time. Between March 15 and September 30, 22,427 tons of ore averaging 3.74% lead, 7.8% zinc, and 9.46 oz. silver was concentrated; producing 1214 tons of lead concentrate averaging 65.3% lead, 9.1% zinc, and 89.7 oz. silver, and 1598 tons of zinc concentrate averaging 45.5% zinc, 1.7% lead, and 29.6 oz. silver. The profit and loss account shows a loss of £2661 for the year.

CONIAGAS MINES, LTD.

This company was formed in 1906 and owns 40 acres of mining claims at Cobalt, Ontario, as well as the entire capital stock of the Coniagas Reduction Co., Ltd., which owns and operates a 60-stamp mill and smelter at Thorold. The capitalization is for \$4,000,000, in shares of \$5 each, all issued, and fully paid. The report for the year ended October 31, 1911, shows that during that period 52,939 tons of ore was hoisted, of which 619 tons, estimated to contain 2,142,536 oz. of silver, was shipped to the smelter and the remainder, averaging 36.3 oz. per ton concentrated, yielding 1418 of concentrate, containing 1,643,616 oz. of silver. The total production was 3,789,274 oz., as compared with 1,929,531 the preceding year. The dividends for the year were \$1,440,000, or at the rate of 36%, a total since 1907 of 71% of the capitalization. The ore reserves on October 31, 1911, were estimated at 132,600 tons, containing 15,645,000 oz. of silver. The profits upon the year's operations were \$1,614,102, making a total balance of \$2,566,505. In addition to the dividends £1500 was paid in directors' fees, leaving a balance to be carried forward of \$1,124,867.

LE ROI NO. 2, LTD.

This company was formed in 1900 with an authorized capital of £600,000, in shares of £5 each (all issued), to acquire the holdings of the West Le Roi Mining Co., Ltd., one-half mile from Rossland, B. C. Further claims were acquired in 1905, and in 1908 the company promoted the Van-Roi Mining Co., Ltd., to acquire an option on a silver-lead property at Silverton. The report for the year ended September 30, 1911, shows that during that period 27,028 tons of ore was smelted, having an estimated content of 1.6% copper, 0.83 oz. gold, and 0.7 oz. silver per ton, and of a net value, after deducting smelting charges, of \$15 per ton. By concentration 1589 tons of concentrate was produced, containing 1.29% copper, 1.425 oz. gold, and 0.75 oz. silver, and of net value of \$25.50 per ton. The receipts from ore and concentrate were £84,806; other receipts made a total of \$91,474. The divisible profits was £30,176, and the balance brought forward £44,005. Of this, £1700 was paid as director's profits and £36,000 as dividends, or at the rate of 6%. It was announced at the annual meeting that henceforth dividends will be restricted to £12,000 per year, in order to accumulate a reserve. The £5 shares were quoted on January 15, 1912, at £3¼ to £7½.

TRETHEWEY SILVER-COBALT MINE, LTD.

This company was formed in 1906 and owns 40 acres in Coleman township, Ontario, adjoining the Coniagas. It is capitalized at \$2,000,000, shares of \$1 each, of which 1,000,000 have been issued, fully paid. The company owns and operates a 100-ton concentrator. The report for the year ended December 31, 1911, shows that 33,339 tons of ore was milled during the year, with a recovery of 486,431 oz., and a further 284,407 oz. was recovered from high-grade

shipping ore, making a total for the year of 770,838 oz. of silver, as compared with 865,777 oz. in 1910. This decrease is explained as due to the greater tonnage of lower-grade ore milled, coming from workings from which the higher-grade ores have already been removed. The gross revenue of the company was \$372,622 and expenditures \$212,316, leaving an operating profit of \$160,306. Dividends amounting to \$200,000 were paid during the year, making the total to date \$761,998. The average price received for silver during the year was 52.87c. per ounce, which will probably be increased during 1912. This company has combined with the Coniagas, Buffalo, and Hudson Bay companies to construct, at a cost of \$20,000, an auxiliary pumping station at Mud Lake. Electric power and compressed air are obtained from the Northern Ontario Light & Power Company.

Taylor Iron & Steel Company

At the annual meeting of the stockholders of the TAYLOR IRON & STEEL CO., held at High Bridge, New Jersey, on March 5, the annual report showed that the earnings for the year 1911 were very satisfactory, although there had been a falling off of business as compared with 1910. Besides the regular 7% dividend on the preferred stock, 6% on the common stock is being paid, and in addition thereto, surplus and reserve accounts increased. The company reports its business as being in a prosperous condition, and its plant and equipment, through recent extensions and additions, in an excellent condition to handle a largely increased business. The following directors were elected: Henry M. Howe, Knox Taylor, L. H. Taylor, Jr., E. H. Earnshaw, H. J. Cochran, Edgar S. Cook, A. E. Borie, V. G. Simkhovitch, and James Imbrie. The officers elected were: Knox Taylor, president; A. E. Borie and H. M. Howe, vice-presidents, and W. A. Ingram, secretary and treasurer.

GEOLOGY AND MINERAL RESOURCES OF A PORTION OF FREMONT COUNTY, WYOMING. By C. E. Jamison. Pp. 90. Map. Bull. 2, Series B, Geological Survey of Wyoming. Cheyenne, 1912. This report is well printed and illustrated, appears to be accurate, and gives due credit to other sources from which information has been taken. It is almost unnecessary, therefore, to add that it belongs to a new series of bulletins issued by the State Geologist of Wyoming. It is to be hoped that more will be issued.

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

THE WORLD'S MINERALS. By L. J. Spencer. Pp. 272. Illustrations in color, index. Frederick A. Stokes Co., New York, 1911. For sale by the *Mining and Scientific Press*. Price \$2.

In this work the author, who is editor of *The Mineralogical Magazine* and is connected with the British Museum, has essayed the difficult task of treating a scientific subject so as to attract the general public. He has been unusually successful, and by means of figures, colored plates, and accurate but entertaining text, has produced a book that may well serve to inform at the same time that it teaches the reader to like minerals. He is right in saying that no book can take the place of actual specimens, but this book is apt to result in the student building up that small collection which forms the best basis for the study of minerals. As a guide to one who has not had the benefit of training in mineralogy it is the best book available. An amateur using it will make mistakes, but at least he will be saved from many errors.

WORKS MANAGEMENT. By William Duane Ennis. Pp. 194. McGraw-Hill Book Co., New York, 1911. For sale by the *Mining and Scientific Press*. Price \$2.

Mr. Ennis, who is professor of mechanical engineering in the Polytechnic Institute of Brooklyn, New York, has done good service in his presentation of the principles of works management. Engineers and managers have been deluged recently with a flood of publications upon efficiency and economy in works management. The author admires what he designates as 'Taylorism,' but has given it only incidental treatment in his work, which covers management in all its phases, and treats it in the light of the prevailing 'efficiency' obsession. The first chapter discusses management units, and is followed by a chapter on cost elements and classifications. Chapter III deals with statistical records, and the following chapter discusses labor. The three following chapters treat of material, burden, and depreciation, and the eighth chapter is an excellent discussion of industrial organization. Principles of accounting form the subject of the next chapter, and the book concludes with a discussion of the plant as the physical basis of the industry. The book is intended as a text for engineering students, and a series of useful problems forms an appendix to the text.

PETROGRAPHIC METHODS. By Ernest Weinschenk and Robert W. Clark. Pp. 386. Ill., index. McGraw-Hill Book Co., New York, 1912. For sale by the *Mining and Scientific Press*. Price \$3.50.

Ever since Sorby applied the methods of grinding, developed in entirely manufacture, to the making of thin sections of rock, the field of usefulness of the microscope in the study of rocks has been expanding. Accurate petrographic determinations are now a pre-requisite to successful determination of the nature of most orebodies, and in the solution of general scientific problems in geology, the help afforded by the microscope has been enormous. This is generally recognized, but it is not so universally understood that success in using the microscope must rest on long preliminary study. There are too many still in the position of the engineer who dropped into the study of a professor at the University of Chicago and announced that he had a couple of weeks of time to spare and wanted to learn how to recognize rocks under the microscope, but didn't care "to bother with the principles of petrography." As to this, the authors of this book say in the introduction: "Special emphasis must be laid upon the fact that simply knowing the appearance of certain minerals in some rocks, or in a large number of rocks, is not sufficient to give that confidence which is necessary in petrographic investigation. As the appearance of one and the same mineral varies greatly in different rocks, a continual source of error is thus intro-

duced, and only general confusion results if the knowledge of minerals is purely superficial and not sufficiently based on microscopic optical methods. The microscopic optical methods necessary for petrographical investigation are discussed thoroughly in the first part of this book. A knowledge of these fundamental principles must precede all petrographic work." The book furnishes the student the material necessary to this preliminary study and the criteria for recognizing the various minerals when the underlying principles have been grasped. It is an excellent book, well prepared, well written, and well printed. The senior author is professor in the University of Munich, and the junior, who is also translator, instructor in petrology in the University of Michigan.

FAULTS AND DYKES. By J. S. Olver. Pp. 298. Ill., no index. J. C. Juta & Co., Capetown, 1911. For sale by the *Mining and Scientific Press*. Price \$7.50.

The title of this work is somewhat misleading, for it is not a general study of faults and dikes, but a minute and detailed study of those of the Witwatersrand, which can scarcely be considered as the only ones worth knowing about. There is, in addition, much in the book beyond a discussion of geological phenomena, notably a discussion of observation and solution of vein phenomena and a study of local sampling problems. The book is divided into two parts, the first general, the second specific. Beginning with simple faulting, Mr. Olver next discusses fault movements and their calculation, and next takes up 'slides,' by which term he designates faulting which coincides with a bedding plane in sedimentary rocks. The following chapter on relative ages of faults is general in its scope, and the whole first five chapters of the book form an interesting complement to C. F. Tolman's 'Graphic Solution of Fault Problems,' which is entirely general in its treatment of faulting. The chapter on observation somewhat overlaps the succeeding chapter on 'reef problems,' and the two were evidently written independently of each other, and without intention to make them chapters of a book. In both are interesting discussions of special problems and much collateral material, such as a condemnation of the 'diamond-drill habit.' Mr. Olver believes that the "use of the diamond-drill is only admissible under exceptional circumstances, and a constant recourse to it should be looked upon as a want of intelligence in the underground management of a mine." Unnecessary driving and drill prospecting to secure information readily obtainable by careful mapping and study of geological phenomena are all too common everywhere, and Mr. Olver's argument is of almost universal application. The first section concludes with a chapter on mine sampling which is lucidly written and full of practical suggestions. The second part of the book is a detailed discussion of the stratigraphy of the Rand. Having the benefit of the work of Messrs. Gibson, Hatch, Corstophine, and Mellor, Mr. Olver should be able to put his discussion upon a high level, and he appears to have done so. He is daring, and extends the Witportje and Orange Grove faults into ground where few will be prepared to concede their existence. His arguments are plausible, however, and students of Rand geology will read them with interest.

The Penhsihu coal mine is 48 miles southeast of Mukden and only second to the Fushun mine in importance. This colliery is now operated under joint Chinese and Japanese management, and when exploited in conjunction with a rich iron mine about 20 miles distant, is expected to blossom into a very lucrative enterprise.

The MIAMI COPPER Co. announces that no dividend action will be taken until the meeting for the quarter ending April 1. The concentrator is now handling 3000 tons of ore per day, and the mine is furnishing this amount of ore to the mill without difficulty.

The OLD DOMINION company of Maine has declared a quarterly dividend of 75c. per share. Three months ago it declared a quarterly disbursement of 50c. per share.

Commercial Paragraphs

George E. Dow, of the GEO. E. DOW PUMPING ENGINE Co., has closed a contract with Willans & Robinson, of Rugby, England, for the right to manufacture the Willans Diesel engine in the United States, Hawaii, and Alaska. A new company, to be known as the DOW-WILLANS DIESEL ENGINE Co., has been organized by San Francisco and London capitalists to manufacture under these patents, and shops are being erected at Alameda, near San Francisco. George E. Dow is president and O. H. Ohlant vice-president of the new concern.

THE JOSEPH DIXON CRUCIBLE Co., of Jersey City, has just put on the market a new chain graphite, especially intended for lubricating the chains of motor trucks and pleasure cars. This preparation is put up in sticks, cylindrical shape, 2 by 8 in., encased in a neat cardboard carton, and weighing about one pound each. It is by far the most convenient chain lubricant on the market, for a bar may be carried on the car ready for use at any time. To apply, it is simply necessary to rub the bar against the sprocket side of the chain. The stick makes it easy to keep automobile driving chains in first-class condition. Unlike oils and greases, it will not collect dust and dirt.

THE INTERNATIONAL MOTOR Co. announces that it has just acquired the properties of the Hewitt Motor Truck Co., and all the business of this concern was taken over on March 1. Sales and executive departments on that date became amalgamated with the International Motor Co., whose headquarters are at Broadway and Fifty-seventh street, New York, with works at Allentown, Pa., Plainfield, N. J., and New York City. The association of the Mack, Saurer, and Hewitt trucks makes the position of the International Motor Co. one of the most formidable, if not the most formidable, single factor in the motor-truck industry in this country. The range of sizes which this organization offers will include every variation in live-load capacity ranging from 1500 lb. up to 10 tons. The acquisitions of the Hewitt interests especially strengthens the line of heavy-duty trucks offered by this organization, as the Hewitt trucks have made a most enviable reputation in the past few years, being in the service of some of the largest wholesale coal dealers, lumber merchants, and engineering contracting firms.

THE C. O. BARTLETT & SNOW Co., of Cleveland, Ohio, in order to keep pace with its remarkable growth, has just increased its capitalization to \$500,000. About 25 years ago C. O. Bartlett, now the company's president and treasurer, laid the foundation of this business. Its operations during the earlier years were the manufacture of oatmeal, barley, pearling, and general mill machinery, but gradually through these years one line after another has been added, and the volume and importance of the business has increased to such an extent that the company now occupies a prominent position as engineers and manufacturers of all kinds of elevating and conveying machinery, complete coal tipplers and coal-handling machinery at the mines and docks, as well as complete coal and ash handling machinery, and complete fueling scows for fueling lake vessels, mechanical driers, both direct heat and steam driers for rendering establishments; also crushed stone, gravel, and sand handling and washing plants, soft mud brick machinery, and complete equipment for the economical handling of nearly all kinds of materials. The company has a large export business, especially in Mexico, Canada, and South America. The increased capital will provide for some enlargements and extensions of the company's business, which may include a foundry. The offices of the company in addition to Mr. Bartlett are E. J. Neville, first vice-president and general manager; H. H. Bighouse, second vice-president; H. L. McKinnon, third vice-president, and I. M. Snow, secretary.

Superheat and high steam-pressures have created a demand for valves of greater strength and durability than those made of cast iron. Anticipating the requirements of

the trade, THE LUNKENHEIMER Co. has designed a complete line of globe, angle, cross, gate, check, non-return boiler stop, etc., made of cast steel, all of which will be found in use and giving satisfaction in a large number of high-pressure power-plants. With the exception of the largest sizes, the Lunkenheimer cast-steel valves are made of crucible steel and not open-hearth or converter steel. Crucible steel is made and melted in closed crucibles, out of all exposure to furnace gases, and solid castings free from blowholes are insured. This is not true of the open-hearth and converter steels, the first of which is heated by blowing hot gases over the molten metal, and the second by blowing them sometimes through the metal. Aside from forming blowholes, these gases form oxides which dissolve in the steel and thereby reduce its ductility and cause a low elastic limit. All of Lunkenheimer cast-steel valves are annealed, which relieves all internal stresses and makes a fine crystalline structure, which is very essential to strong steel. The Lunkenheimer Co. claims that its valves are the only ones which are made to meet the specifications of the American Society for Testing Materials, and that they are the only steel valves containing less than 0.05% of either phosphorus or sulphur. The tensile strength of Lunkenheimer cast steel is about 80,000 lb. per square inch, with a safe elastic limit and excellent elongation. For various pressures and degrees of superheat and to meet the requirements of engineers who differ as to the material used, Lunkenheimer cast-steel valves are made in two combinations of material as regards the trimmings. For lower pressures and degrees of superheat, the company manufactures a large and complete line of cast-iron and 'puddled' semi-steel valves. The Lunkenheimer Co., Cincinnati, Ohio, will send descriptive matter pertaining to its cast-steel valves to anyone interested.

Catalogues Received

'C-12,' the new catalogue of the DODGE MANUFACTURING Co., is now being distributed among the trade. It contains 413 pages, beautifully printed and illustrated, and describes and lists in complete form the goods the Dodge company makes at Mishawaka, Indiana. As an introduction, the first pages are devoted to interior views of Dodge foundries, machine-shops, power-plant, and branch houses; then follow tables for laying out shafting, horse-power of steel shafting, dimensions, etc. Every product of the company, a complete line of power-transmission machinery and appliances, elevating and conveying equipment, rope-driving system, and water-softener apparatus, is completely described and listed. Considerable space is devoted to the Dodge friction clutch as an accident-prevention device. Concluding pages give a little history of the transmission of power by manila rope with illustrations of a number of striking installations, heavy engineering work, and the Eureka water softener and purifier. This book marks the close of another year in the life of the company. Established in 1878 by Wallace H. Dodge, it has been an important factor in the industrial life of America. First incorporated under the laws of Indiana with a capital stock of \$50,000, this has passed over the million mark. Since its inception, the Dodge Manufacturing Co. has never had an unprofitable year. Considerably more than \$2,500,000 has been earned for shareholders, and of this more than \$2,000,000 has been added by reinvestment to the company's resources. The business got its start through the invention by Mr. Dodge of the split-wood pulley with interchangeable bushings, a revolution in the pulley art. At that time the plant occupied only a few acres of ground in Mishawaka. Today there are 63 acres of ground space and over 21 acres of floor space. This great factory is equipped with every facility required in the economic and efficient operation of various departments, and this is supplemented by a vast selling organization, taking in branch houses at New York, Boston, Pittsburg, Philadelphia, Cincinnati, Minneapolis, Chicago, St. Louis, and Atlanta, and stock-carrying agents in every power-using community. The company enjoys a world-wide reputation both as to products and management.

EDITORIAL

LARGE corporations seem to be doing very well in their disintegrated condition, and Standard Oil shares have risen in price considerably since the dissolution of the holding corporation.

IN the account of the Mineral Resources of Bolivia by Mr. Carlos Sanjines, that we published March 9, the pertenencia was defined as consisting of 100 square metres. This was an error, as readers familiar with land measure in Spanish American companies will have noticed. In Bolivia, as elsewhere in South America, the pertenencia is equivalent to one hectare and is 100 metres, or approximately 328 feet, square.

SHEEP, sunshine, and silence are giving way to the hum of industry in New Mexico, and we are glad to present this week an account of the great Chino mine, written by Mr. James O. Clifford, an engineer long familiar with the Southwest, and to supplement it with an authoritative account of the mill, written by Mr. John M. Sully, who has seen notable changes in New Mexico, though none more striking than at Santa Rita, and in which he has played so successful a part.

AN interesting comparison between the Yukon and Alaska is made this week by Mr. Guy A. R. Lewington, a well informed American living at Dawson. The marked contrast is not due to dissimilarity in the natural resources west of the international boundary from those east of it, but is wholly the result of difference in two legal codes. It is worth noting that at Dawson two attorneys handle all the litigation of the town, while at Fairbanks, which is of about the same size, there are about fifty.

MUCH of the loss of life in railroad accidents is due to faulty metallurgy, since many of the wrecks are due to broken rails. Unfortunately it is impracticable to entirely eliminate bad rails by even the most rigid system of inspection, since oftentimes a flaw is too deep seated to be detected by external examination. A recent counter proposal is the removing of fast trains from the schedules, but the disadvantage of this method of procedure is evident. The fastest trains in the world are operated in France and England, without the resulting losses of life we here sustain. Rather than pay for complete safety, both the public and the corporations are willing to take a chance.

INTERNATIONAL economic relationships are clearly shown by the collateral effects of the strike of coal miners in England. Shipping interests with South America are severely hampered by the lack of coal for steamships, and without steamships the supply of food products from South American countries ceases, and the same is true of trade with Denmark. The mineral industry can show its examples as well. Concentrate from mills in Korea is smelted at Tacoma, while California smelters operate on Australian, German, or Chinese coke. Antimony residues from China go to Belgium for re-treatment, and recently a carload lot of zinc ore was shipped from Africa to Denver for experimental purposes. The mining engineer is perforce cosmopolitan.

NOTABLE progress has been made by the United States Smelting, Refining & Mining Company since its formation in 1906, and its subsidiary companies in the United States and Mexico have done well. Its Utah subsidiary, the United States Smelting Company, is about to issue \$10,000,000 in bonds to acquire coal properties and necessary railroad connections.

CONDITIONS in Mexico continue much disturbed, though the mineral industry is again doing remarkably well under adverse conditions of work. Mine-owners in Chihuahua are said to be worried over the payment of the tax on output, as the Federal tax office has been closed and the insurrectionary forces have opened another. Fearing lest if paid to the revolutionists the tax may be required to be paid again to the central government, and knowing that unless paid by April 1 a fine of 50 per cent of the total sum may be imposed, our neighbors to the south are in an unpleasant dilemma.

A CURIOUS feature of the practice of many technical journals is an apparent unwillingness to acknowledge the sources from which material is drawn, apparently from a belief that by crediting other journals with material taken from their columns the impression is conveyed that the journal according credit is unable to secure original material of value. Our own belief is that our subscribers wish to receive that which is important and interesting to them, regardless of whether or not it has previously been published elsewhere, and we do not believe that our columns lose dignity through the occasional line of acknowledgment. From time to time we have referred in vigorous terms to the practice of certain journals in reprinting material from our columns without according credit. An interesting variation of this practice is seen in the issue of the *South African Mining Journal* for February 17, which reprints our editorial of January 6, 'The Year Among the Gold Mines,' in the form of an original article, altering the wording sufficiently to make it appear that only the information regarding California had been obtained from our columns. When you are 'lifting' material, gentlemen, why not be wholehearted about it; or, better still, make full acknowledgment?

THAT more engineers are now being turned out yearly by the technical schools than the country can assimilate, is the view of Mr. H. S. Pritchett, in his annual report as president of the Carnegie Institution for the Advancement of Teaching. This is the case, if it is to be supposed that the young man of engineering training must necessarily remain in the work of his profession, but this is neither true nor desirable. The enormous fabric of modern industry hinges upon the mechanical and chemical arts in a multitude of ways, and no better training for a business vocation can well be imagined than a thorough grounding in the fundamental principles of physics and chemistry, with their applications. More significant is the fact that during 1910 thirty-eight different degrees were conferred upon 3713 students by 102 institutions. In Pennsylvania there are 13 engineering schools, of which 6 have less than 40 students each. No adequate reason for the continued existence of a multitude of small and ill-equipped schools can be advanced; nor should the rights of the student be ignored. With a limited amount of time and money to invest in his education he should not be subjected to pressure to invest it in a local institution, when a more adequate return can be secured elsewhere. Nor is such a variety of degrees necessary, and their multiplication is more likely to produce a crop of under-done specialists than to meet an industrial need. The Foundation has an excellent field for its activities in directing the lines of growth of secondary education, and

the storm of protest which it occasionally evokes may be taken to indicate that it is making its influence felt. It is interesting to note, in passing, that the fifteen teachers whose deaths are recorded in this report, lived on the average less than three years after the receipt of a retiring allowance.

Government Bureaus and Potash

Much attention has been attracted recently by reports in the public press that the United States Geological Survey and the Bureau of Soils of the Department of Agriculture have jointly discovered immense resources in potash salts existing in the widely known Borax lake of San Bernardino county, California. There can be no question that the potash industry is an important one to the American people, since we annually import over five million dollars worth of chloride salts, kainit worth more than two millions, sulphate worth nearly two millions, and other potassium salts of considerable value, while the economic fact that no important sources of supply exist in this country, thus placing it at the mercy of the German producer, has been strongly emphasized by the market situation which developed last year. Under the circumstances it was highly proper for those bureaus whose function it is to foster the agricultural and mineral industries, to undertake to discover supplies of potash salts within the boundaries of the United States.

Purposes and methods are two different things, however, and while commending the one we beg to deprecate the other. The function of government bureaus is to disseminate accurate information, not to diffuse sensational statements. Five years ago members of the Geological Survey embarked on the latter course in connection with the investigations concerning black sands and their treatment, and the echoes of exaggeration based on 'preliminary statements' have scarcely yet completely subsided. At that time we expressed our opinion that the "researches into black sand are affording more ammunition to irresponsible promoters and to a sensational press than they are actually improving the treatment of a material, the existence of which was known long before the much-advertised experiments were made." On another page we give the text of a press bulletin sent out under the joint auspices of the Bureau of Soils and the Geological Survey. It announces that as a "conservative" estimate the amount of K_2O in the form of potash salts existing in solution in the waters of Borax lake is 4,000,000 tons, and it is possible that it may exceed 10,000,000. This has been "discovered" by representatives of these bureaus, who have analyzed samples of brine taken from six wells in an area of eleven square miles, from which, by facile leaps, the conclusion is reached that the brine contains an average of 6.78 per cent K_2O and constitutes 25 per cent of the salt body covering this area. In the prospectus of an irresponsible promoter this would be conservative; in a publication of a scientific bureau it is a disgrace. These remarkable results have all been obtained from "existing data" except the "discovery" of the potassium content of brine samples taken from wells put down by private individuals for the purpose of testing these salt bodies. If this were in fact a discovery the original analyst might be severely condemned. Since it, however, is merely a public statement of what was previously known to those who spent money to determine the facts, its importance diminishes. Potassium occurs in nature in a variety of minerals; some of which are commercially valuable and others are not; which of these occur in these salt deposits? How may they be made available? Are the data given accurate or merely wild guesses? The Survey has said too much not to say more; it is 'up to it to make good.' In any event, such methods of self advertisement by government bureaus are at once unbecoming and productive of

no good results. Shares in irresponsible enterprise can be sold through newspaper publicity; economic development works through other channels.

The Balance Sheet in Smelting

One of the fundamental tenets of biology is that an individual organism in its life history roughly recapitulates the history of the development of the race or species to which it belongs. A similar conception is of great service in considering the development of an industry, which in many respects resembles an organism. A Goldfield Consolidated is preceded by shallow untimbered shafts, a whim or windlass, and crude milling tests to determine the worth of the ore. The relative importance of the primitive stages depends entirely upon the conditioning circumstances; some mines exist for years in the whim stage of development, and, indeed, never advance beyond it, while in others it may be so brief as to easily escape notice. But the economic history of an enterprise, whether it be a Goldfield Consolidated or Dick Smith's claim on Buck creek, consists in a series of adjustments to the governing circumstances. On another page, in the course of an admirable article upon the mineral losses in gases and fume which occur in smelting, Mr. F. G. Cottrell remarks that the copper blast-furnace is today one of the crudest appliances in engineering practice, and suggests that the reason for this backward stage of development can be found in the difficulty of interpreting small-scale smelting experiments in terms of full-scale working conditions, aided by the financial considerations that with a rich mine the natural desire has been to secure tonnage to increase profits, while with poor mines there existed an equally natural reluctance to undertake experiments which would surely be expensive and possibly unprofitable. Mr. Cottrell is a chemist of distinction, and consequently looks upon the art of smelting with a critical eye; in speaking to an association of chemists he may have thought it unnecessary to introduce other practical features which, when considered, do not indicate that metallurgists have been remiss in the development of their art. The most important of these is the state of flux in which a smelting industry constantly exists. In the case of a sugar factory, for example, the plant can be constructed and operating methods devised upon the basis of a fairly uniform raw material. A plant to make sugar from beets is a concrete problem which offers but slightly varying phases from year to year; minute studies are possible and the introduction of slight refinements and economies of practice are economically advantageous. But suppose a plant were required to make sugar from a mixture of beets, cornstalks, and alfalfa and the relative amount of each available varied from month to month and year to year. In the latter case the energies of both the management and the technical staff are largely absorbed in continuing operation at a profit, rather than in introducing refinements of practice. Surely the skill required in readjusting inexpensively a plant constructed for work of a certain character so that it will continue to work on material of radically different character, is of no less high order than the skill that devises the finer points of advanced practice. Scarcely a smelting plant in the United States, not of recent construction, is treating an ore like that for which it was constructed. In Colorado, copper smelting has been discontinued, the lead smelting plants are called upon to solve new problems arising from variations in the smelting charge, every year, and in other states there are cases of the metallurgist being called upon to construct a copper smelting plant for what afterward turns out to be a zinc mine. The differences in the chemical and metallurgical industries are fundamental; the former deals with raw materials of known composition

and assured character, while next year's supply of ore is in the ground, and no one can tell exactly what it will be like until it has been taken out. In building a house in town it is practicable and desirable to put in open plumbing and electric light; in the construction camp dependence is placed on the tin washbasin and the tallow candle. A copper blast-furnace is admittedly a crude appliance; so is a shovel a crude tool, but both do the work they are required to do more cheaply and effectively than any substitute can.

Much in Mr. Cottrell's article is suggestive of thought, and may well be carefully considered. One point which deserves further attention is the question of reducing SO_2 to the form of sulphur, or else preventing the original oxidation of sulphur, eliminating it in the elementary form. Both chemical and mechanical factors enter into this problem. In the case of an ore carrying 40 per cent sulphur and 4 per cent copper, the sulphur which is burned furnishes the heat for the endothermic reactions of smelting, the coke employed chiefly acting mechanically in keeping the charge open. If no sulphur is to be burned, then sufficient coke must be used to furnish the heat necessary, with the result that the smelting cost is increased 75 cents per ton, or nearly 1 cent per pound of copper produced, even assuming that the variation from the standard method and type of construction does not otherwise increase the cost of operation. In the case of reducing SO_2 to elemental sulphur the economic result is the same; you are equally impoverished by paying out of the contents of the left pocket instead of the right. The manufacture of sulphuric acid, and its employment for the production of superphosphate fertilizers offers no such easy solution as many of the early hasty writers on this subject assumed. The total quantity of sulphuric acid produced in the United States in 1905 was 1,642,262 tons, or less than double the possible output of a single large smelting plant. Of this, less than 200,000 tons was employed to manufacture 1,670,978 tons of superphosphates and 781,354 tons of ammoniated superphosphates. Out of a total of 3,591,771 tons of fertilizer of all kinds produced in the whole United States in 1905, less than 57,000 tons was produced west of Nebraska. It is quite true that the consumption of fertilizers in the Western states will increase as agriculture is developed upon a more intensive scale, but when a single large smelting plant can furnish enough sulphuric acid to quadruple the present production of phosphate fertilizer, the outlook in that direction is not encouraging. Certain smelting plants will be able to produce acid profitably, the majority will not. The placing of plants so that the escaping SO_2 will not damage vegetation will be effective in other cases, and the perfecting of leaching processes has already been greatly stimulated. The solution of this problem is an economic one, and must be attacked on economic lines. It may well be asked whether it may not be better for the American commonwealth to have smelting industries flourish, even at the expense of neighboring agriculture, than to restrict metallurgy unduly. Farms exist everywhere, but smelters can only exist in the comparatively few places where the sum of governing conditions permit; it might be to the advantage of the commonwealth to give the smelter the right of way, just as railroads have been accorded the privilege of exercising the right of eminent domain. This may be a wrong view; it is at least a possible view. Political conditions, by which the great number with small interests at stake are able to outweigh the few with great interests at stake, ought not to supersede a clear-sighted view from the standpoint of economics. Questions such as these should not be approached from the standpoint of prejudice and self-interest, but from the standpoint of securing the greatest good to the greatest number. Meanwhile copper smelting lingers in a stormy sea.

Lessons From Recent Mine Disasters

By JOSEPH A. HOLMES

*It would be unfortunate, as well as unpardonable, if from the many American mine disasters of the past few years some lessons have not been learned that may help to prevent or minimize future disasters, or reduce the loss of life resulting from them. I shall endeavor to call attention to a few of these lessons that stand out most prominently. First of all, attention may be called to the fact that satisfactory progress is not yet made in reducing the loss of life in our mines; and this progress never will be made without getting away from the theory and down to actual practice, and developing that hearty determined coöperation between the mine-owner and the mine worker which is absolutely essential to success. Of the fatalities in coal mines for 1910, 47% were from falls of roof and coal; 16% were from mine-cars; 18% were from mine explosions; 4% were from explosives; 2½% were from electricity. Of the total fatalities, 90% were underground, and 10% above ground.

LESSONS FROM MINE FIRES

Mine disasters have resulted from mine fires, gas explosions, or dust explosions, or a combination of two or all of them. Two of the most notable recent disasters from mine fires are the Cherry disaster of November 13, 1909, where 259 men lost their lives (the fire having started from the burning of hay in the mine stable, and the Pencoast mine disaster, near Scranton, where 72 men lost their lives from a fire which appears to have started from the inflammable material at one of the underground power stations. In neither of these two mine-fire disasters does there appear to have been any accompanying gas or dust explosion. It is evident that the men were suffocated or poisoned by the gases generated from the fire (excepting, of course, the few who were killed by the heat of the fire itself).

The two most important lessons taught by these two disasters are: the risks that always attend the practice, which is entirely too common, of carrying into mines inflammable materials and keeping these materials in the mine; and second, the inadequacy of the methods and equipment for fighting and extinguishing mine fires. Of course, timber must be used in the mine, and no economical method is now known for fireproofing this material. As long as mules are kept in the mines, certain materials must be carried into the mines with which to feed them; but if baled hay must be taken into the mines for feeding purposes, it can be easily and superficially wet either by sprinkling or dipping it quickly into a tank of water, and it can be carried in closed cars. By all means the easiest way to prevent the risk of fires in mine stables is to keep these stables outside of the mine.

LESSONS FROM MINE EXPLOSIONS

Under the new system now being introduced, men wearing different types of breathing apparatus are expected to go into the mine in advance to investigate the condition of the mine, adopt the necessary steps toward ventilation, and find and extinguish smoldering mine fires; also find and rescue any persons who may still be living in the remoter portions of the mine. This modern type of rescue work is new; it is still imperfect and open to improvement. It frequently arouses criticism on the part of those who watch but do not take part in its progress; and under the circumstances this is not to be wondered at. The special breathing apparatus of today is heavy and cumbersome, and the oxygen supply that it carries does not last as long as it should. Nevertheless, progress is being made, and the results of each year's experience will prove more and more satisfactory and encouraging. Recent experience

in this new type of mine-rescue work at Briceville and other mine disasters has taught some important lessons. One of these is that there should be at every mine or every group of mines a number of young men trained in the use of modern breathing and rescue equipment, who are familiar with the mines in that particular district; also that the men who are trained in this work should be actual miners, men thoroughly acquainted with the mining conditions. They should be sound in health, and they should be men who are not easily excited, but remain cool and thoughtful at the time of greatest risk.

TRAINED RESCUE MEN AT EVERY MINE

There should be at every mine or group of mines a sufficiently large number of men, equipped with breathing apparatus, who can begin the rescue work in the mine as soon as the disaster occurs, expecting to be relieved or aided when other rescuers arrive.

The more training and experience a miner has in this new type of rescue work, the more efficient he becomes, and the more he can accomplish within a given space of time; and the less is the risk of losing his own life. But even after a week's training such as is given by the Government mine-rescue cars, a miner should be prepared to take part in the actual rescue work following a mine disaster. Under no ordinary circumstances should a man who has had no previous training in wearing the helmet outfit, make a trip to a remote part of the mine filled by poisonous gases; this should be done only by men who have already had such training for at least a week.

The number of men trained and supplied with modern rescue equipment should be rapidly and greatly increased in every important coalfield. Within a few years more it is hoped this system will be carried forward to such an extent that in the case of such a disaster as that at Briceville, and within a few hours after a disaster, there can be assembled promptly from 50 to 100 men, well trained and fully equipped with special breathing apparatus, and also fairly familiar with the immediate mining district. With a force of this kind it would be possible within a few hours to reach all the remoter parts of the mine. With the present limited number of trained men in different parts of the country, this is impossible. At no disaster previous to that at Briceville has it been possible to bring together within a short time as many as a dozen experienced and well equipped men. For a short time at Briceville, there were as many as 20 men who had some training with helmets, but one-half of these were without actual experience, and not one of them was familiar with the mining condition in that region. A week was therefore required to accomplish results which should have been accomplished in less than 24 hours.

With a general improvement of mining conditions and increased efforts to prevent or limit dust explosions through sprinkling, exhaust steam, stone-dust, or ashes, or otherwise, it is becoming more and more likely that explosions, which may occur in spite of such precautions, will be limited to certain portions of the mine. In such cases, the chances of men escaping through other openings, or living in the mine after the explosion for several days, by putting up barricades in remote parts of the mine, will be greatly increased. While, therefore, all will agree that the most important thing of all is to prevent mine disasters, it is also necessary to endeavor as rapidly as possible to improve facilities for rescue and first-aid work.

THE East Rand Proprietary Mines operating results for January 1912 were: 820 stamps milled 164,550 tons; 57,340 oz. recovered from all sources; £67,108 profit for the month. The clean-up of the cyanide works commenced on the morning of January 26 and was completed on January 28; the clean-up of the mills commenced on the morning of January 30 and was completed the same day. Because of opinions expressed by shareholders, gold reserves have been abolished, and the estimated value of the reserve, namely, £74,638 has been transferred to profit and loss account for the year 1911.

*Excerpt from an address delivered before the Southern Appalachian Coal Operators' Association, Knoxville, Tennessee, February 13, 1912.

Mining Copper Ore at Chino

By JAMES O. CLIFFORD

The Chino Copper Co. owns several extensive groups of mining claims at Santa Rita and a 3000-ton concentrator at Hurley, both in eastern Grant county, New Mexico. Santa Rita is on a branch line of the Atchison, Topeka & Santa Fé railroad, fifty miles north of Deming, New Mexico. With the possible exception of the Keweenaw peninsula, Santa Rita is the earliest known copper-producing district in the United States. About 1780 the copper mines at Santa Rita were acquired from the Indians and operated until 1840 by Spanish successors, to supply copper for the Mexican coinage. So far as known, only the high-grade seams of native copper that permeate the mineralized zone of the district were mined and shipped by pack-trains to Mexico City by way of Chihuahua.

From 1840 to 1900 the mines were worked only intermittently, and then chiefly by American and Mexican lessees. No authentic records exist giving the production during the period 1780 to 1900, but the value of the copper mined is estimated at \$15,000,000. Three years ago the

believed to have originally overlain the region of the present orebodies, and that through thorough oxidation and degradation the contained copper was dissolved and precipitated in the underlying rocks. The area of these altered limestones was doubtless considerably greater than the existing one. The intrusive rocks comprise quartz-monzonite and quartz-diorite porphyries. The former occurs as an elongated mass that has domed up the sedimentaries and then been partly exposed by their subsequent erosion; it also cuts the sedimentaries in the form of dikes and irregular intrusive projections from the main body. The quartz-diorite porphyry cuts the quartz-monzonite porphyry and the sedimentaries, and occurs as dikes and intrusive sills along the outer rim of Santa Rita basin. The effusive rock is represented by an extensive flow of reddish rhyolite to the north and south of Santa Rita, a remnant of which is a prominent feature of the eastern landscape and is called the 'Kneeling Nun.'

Santa Rita basin is merely a local widening of Santa Rita creek and is about a mile square. Quartz-monzonite porphyry, upon which rests a block of slightly altered Cambrian quartzite, 200 to 300 ft. thick, constitutes the floor of the basin. Altered limestones, porphyry, and rhyolite chiefly form the sides. The ore exists as veins in quartzite and porphyry, contact-metamorphic deposits, and deposits of secondary enrichment.

Chino Ore Deposit.—This occurs in the form of a horse-shoe of mineralized quartz-diorite porphyry encircling a barren core of slightly altered quartzite. This mineralized quartz-diorite contains a great variety of copper minerals: chalcocite and native copper, however, predominating. Rich seams of native copper permeate the entire mineralized zone. The dissemination of the orebody is not so uniform as in the case of some of the other 'porphyries'; consequently the copper content of the ores mined will be subject to fluctuation. The average thickness of the orebody is said to be 110 ft., capped by overburden averaging 85 feet.

Prospecting and Development.—The ore deposit has been prospected by churn-drilling. In that manner 54,970,000 tons of ore is said to have been blocked out, having an average copper content of 2.24% per short ton.

Mining Operations.—The management states that at least 60% of the ore developed can be mined by steam-shovels. Stripping operations are several years in advance of mill requirements. The cost of stripping and mining is said to be about the same as at the Utah Copper and Nevada Consolidated properties.

Progress in Bolivia

The copper production of Peru increased last year by 142%, of Chile by 28.7%, and of Bolivia by 20%. The Rio Blanca smelter, in which a majority interest is in American hands, is at present under a receivership, owing to local litigation. The plant, which has been constructed for about three years, has remained practically idle. Railway construction in Bolivia progresses slowly. It is believed that the Rio Mulatos to Potosi line will be ready for the transportation of passengers and cargo in March or April. There is very little work now being done on the Oruro to Cochabamba line, and it is said that this line will never be finished any farther than Changolla, which is about on the border line between the departments of Oruro and Cochabamba. As far as the Arica-La Paz line is concerned, the date of its formal opening will probably be September 18, though there is much doubt whether any freight will be carried before the early part of 1913. There is still much to be done on this line. According to local reports, Señor Patiño, the owner of the Uncia and other large tin-mining properties, is endeavoring to arrange a tin trust, but details are wanting.—*The West Coast Leader*.

REPORTED discovery of large diamond deposits along the Rio das Gareas, in Matto Grosso, Brazil, have attracted great attention and the government has taken steps to protect its own interest in the deposits.

MAP OF NEW MEXICO.

Chino Copper Co. acquired control of the principal mining properties in the Santa Rita basin, among which are the Romero, Montoya, Santa Rita, Hearst-Carraseo, Texas Flat, and Whim Hill groups of mining claims, together with several other groups of lesser importance. The total area of mineral ground controlled by the company is about 2000 acres, most of which is patented.

General Geology.—Santa Rita, although officially included in the Central mining district, is distinct geologically from the region about the town of Central, and is therefore considered independently. Santa Rita and Hanover, being in the same geological horizon, are considered together and referred to as the Hanover-Santa Rita mining district. Hanover adjoins Santa Rita on the northwest, being separated by the low divide between Hanover and Santa Rita creeks. The average elevation of the district is 6500 feet.

The geology of the Hanover-Santa Rita district is complex, and comprises rocks representative of sedimentary, metamorphic, intrusive, and effusive types. The sedimentary series consist mainly of Devonian limestones and shales and Carboniferous limestones, about 900 ft. thick. The metamorphic rocks are sediments altered by porphyritic intrusions, and are about 300 ft. thick. This contact-metamorphosed limestone, containing cupriferous sulphides, is

Milling the Ore of the Chino Mine

By JOHN M. SULLY

Water-Supply.—Water is obtained from four pumping stations; one at Apache Tejo, five miles south of Hurley; a second at B ranch, one mile northeast of the mill; a third on Whiskey creek, five miles west of the mill; and the fourth on Cameron creek, one mile east of Whiskey creek. The Whiskey creek and Cameron creek supplies use the same pipe-line. The Apache Tejo pumping station is equipped with one Aldrich quintuple-gear electric-driven pump, a second pump being on the ground for installation as a reserve. The B ranch, Whiskey creek, and Cameron creek stations are equipped with Aldrich triplex-gear pumps, motor-driven. The power is transmitted to each sub-station at 24,000 volts, and transformed to 480 volts. The water from these stations is pumped to a 3,000,000-gal. storage reservoir at Hurley.

Plant Buildings and Concentrator.—The site selected for

ft. long by 16 ft. 7 in. wide. A bay has also been provided for the permanent oiling system.

The building is a steel structure, covered with galvanized iron. The structure in the engine-room portion has been designed for and provided with a traveling crane of 40,000 lb. capacity. The boiler-room is arranged with coal bunkers, into which the coal-cars can be directly dumped and the coal fed, without rehandling, to the Green stokers.

The steam-generating plant consists of eight 445-hp. (nominal rating) Heine water-tube boilers set in batteries of two boilers, carrying 175 lb. steam-pressure as a working load. One battery (two boilers) is equipped with Green chain-grate stokers. A second battery of boilers is now being equipped with stokers, and the remaining batteries will be equipped before July 1, 1912. These stokers have shown great efficiency in the burning of the cheapest

CHINO SHOVEL PITS, SANTA RITA, NEW MEXICO.

the mill of the Chino Copper Co. at Hurley, 9½ miles from the mine at Santa Rita, is on the edge of the mesa on the south bank of Whitewater creek at a point three-quarters of a mile distant from the Santa Fé railroad, and where favorable grades and ample room for yards could be found between the Santa Fé and the mill proper. The slope of the ground was such that a minimum amount of excavation was necessary to give the right slope through the mill building. The power plant is south and west of the mill, the coal bunkers being set on a line with the tracks over the crude-ore bins, permitting the placing of cars over the bunkers of the power-house.

Power Plant.—The power-plant building is 114 ft. 3 in. wide by 180 ft. long. The boiler-room occupies 48 ft. 3 in. of the width, and the engine-room 66 ft. The floor of the boiler-room is 16 ft. below the engine-room floor. A suitable material for the engine bases was found within a foot or two of the surface of the ground, and the foundations of the engines were brought up to such a height as to leave ample room under the engine-room floor for all auxiliaries without the necessity for excavation. A switch-board bay is provided on the east side of the building 54

grade of slack coal and insure ample boiler capacity for all anticipated needs, as well as a minimum consumption of coal and labor charge. Apparatus for the removal of ashes has been ordered (Green suction ash-handling system) and preparations are now in progress for its erection. The boiler-room costs for the generation of steam will be brought down to a minimum. The smoke-stack is of the self-supporting type, built of steel, 12 ft. in diameter, and erected on a reinforced-concrete base, its total height being 180 ft. Three compound duplex boiler feed-water pumps of the outside packed plunger type, together with necessary feed-water heaters, are provided.

Engine Generator Equipment.—The equipment of the electrical generation plant consists of three Nordberg double-expansion engines, operating at 100 r.p.m. The high-pressure cylinder is 27 inches in diameter, the low-pressure 60 inches in diameter, stroke 48 inches. The generator is an Allis-Chalmers, mounted on the crank shaft, of 1250 kw. output and of the 3-phase, 60-cycle type, generating at 480 volts. A full equipment of auxiliaries for running condensing is provided, the circulating pump equipment being in duplicate. For furnishing power to Santa

Rita and the various sub-stations the current is stepped up to 24,000 volts, step-down transformers being provided at the points of use. The entire plant has been provided with the best of apparatus with a view to economy of operation and low power-cost.

Plant Buildings.—The machine-shop is placed in line with the concentrator to the south and at the most convenient place for the handling of the heavy machinery from the mill for repair, by the industrial railway, the town of Hurley lying back on the mesa, and to the west of the crude-ore bins. The carpenter-shop lies to the north of the concentrator building and within a convenient distance of the railroad tracks, the entire arrangement of the plant buildings being compact and convenient for all purposes.

The crude-ore bins and coarse-crushing plant form one structure, the crude-ore bins having a capacity of approximately 18,000 tons of crude ore. The coarse-crushing plant has been designed to permit of a duplicate set of machinery being installed if necessary at a future time. The present equipment consists of one No. 8 gyratory crusher and one set of 72 by 20-in. Garfield rolls, the rolls weighing 175,000 lb., together with the necessary elevator,

the head sample after the ore has been crushed in the coarse-crushing plant. The head sampler, together with the sampling machinery, forms part of the structure to the west of the fine-ore bins.

The fine-crushing department of each section is equipped with two 42 by 16-in. rolls, each weighing 65,000 lb. There are two elevators which receive the feed from the fine-ore bins and elevate it to three impact screens each, the screened material from the rolls being fed over two impact screens for each set of rolls. The fine-crushing department is so placed that the rolls can be readily dismounted and taken to a platform where the parts can be handled by the electric crane which occupies the next bay over the Chile mill floor. This crane is so placed that the Chile mills, of which there are three 6-ft. mills to each section, are easily accessible for handling for repair purposes. In this Chile mill bay and under the Chile mill floor is placed the main jack shaft from which the drives for the rolls, the Chile mills, and the necessary machinery for the fine-crushing department are taken. In the fourth bay are placed the wet elevator, the various classifiers, and the Garfield tables. The classifier equipment consists of four 4-spigot classifiers; four

CHINO POWER-PLANT, MILL, AND MACHINE SHOPS, HURLEY, NEW MEXICO.

conveyors, and grizzlies. The crude-ore bins are equipped with conveyor belts and automatic feeders, the bins being 300 ft. long by 35 ft. wide, and carrying two lines of tracks.

The coarse-crushing plant is connected with the fine-ore bins of the mill section by an inclined conveyor 184 ft. long between the edges of the buildings, the total length of the conveyor being approximately 262.5 ft. between centres.

Mill Building.—The mill building is a steel structure on concrete foundations, enclosed with galvanized iron. The floors are reinforced concrete. Each section of the mill is 50 ft. wide by 341 ft. long, between centres of the extreme column lines. The total size of the five sections will be 250 ft. wide by 341 ft. long.

The fine-ore bins are round steel tanks with reinforced-concrete bottoms, there being two to each section. Each bin has a capacity of 1000 tons, approximately, there being therefore 2000 tons of storage to each section. Each bin is equipped with two feeders and one conveyor-belt. At the head of the inclined conveyor, at its discharge, there is being installed an automatic sampler for the taking of

5-spigot classifiers, and two 3-spigot classifiers, all of the Richards-Jamney type. The Garfield table equipment consists of four 6-ft. Garfield tables and ten 4-ft. Garfield tables. In the fifth bay are placed the first set of cones, 10 to each section, which takes the overflow from the four 4-spigot classifiers; and six Willley tables.

The rest of the various floors in the mill are occupied by the Isbell vanners, of which there are 96 to each section, the remaining 30 cones being so placed as to take the overflow from the four 5-spigot classifiers and the two 3-spigot classifiers and give the proper distribution to the vanners which they feed; there being 72 smooth-belt vanners and 24 sand vanners.

The mill is further equipped with two concentrate pumps for handling the concentrate from the sumps under the mill and with duplicate circulating pumps for the overflow water from the cone settling tanks. Each section of the mill is operated by a transmission circuit and motors separate from every other section of the mill; everything being designed to permit of one portion of each section being shut down without interfering with the whole section of the mill or any one class of machines. All of the launders throughout the

mill are placed with the same object in view, namely, in such a manner that switches of feed may be made from one portion of a section to another. In case of accident or necessity for repairs in one portion or one part of it, the feed can be diverted so as not to necessitate the entire shutting down of all of any class of machines. It is also so arranged that ore in each section can be sampled separately, there being at the same time an automatic tailing sampler for the whole mill.

Flow-Sheet.—The mine-run ore is delivered on top of the coarse-ore bins, where it is dumped on grizzlies made of rail, having an opening 14 by 16 in. From the coarse-ore bins this mine-run ore is fed through any necessary number of feeders of the caterpillar type to a traveling belt-conveyor which delivers the ore to a bar grizzly of 1 in. spacing, the undersize going immediately to a belt-conveyor for delivery to the fine-ore bins, and the oversize going through the gyratory crusher and being crushed to approximately $2\frac{1}{4}$ in. This crushed material is then elevated to another bar grizzly, the undersize going at once to the belt-conveyor for the fine-ore bins, the oversize passing through the 72 by 20-in. rolls. This crushed material drops immediately upon a coarse grizzly for the taking out of any native copper that may have been flattened in the rolls, the undersize being delivered to a screen grizzly having a $1\frac{1}{4}$ -in. opening. The oversize goes back to the elevator and the undersize is delivered upon a conveyor. The crushed ore, therefore, has a maximum size of between a $\frac{3}{4}$ and 1-in. cube. This plant has operated up to a capacity of 450 tons per hour without difficulty.

The conveyor to the fine-ore bins delivers upon a cross-conveyor for the distribution to two bins of each section. From each fine bin there are two caterpillar-type feeders delivering upon a belt-conveyor. These caterpillar feeders are so arranged that the feed can be varied. The conveyors under the fine-ore bins deliver to two elevators, No. 1 and 2. They in turn deliver at the top of the mill to six impact screens having an opening of approximately 0.1 in. The oversize goes to two 42 by 16-in. rolls, the product of these rolls going to four impact screens having an opening of approximately 0.1 in. The oversize is returned to elevators No. 1 and 2. The fine-crushing plant of one section has handled 1300 tons without difficulty.

The undersize of the above set of impact screens is delivered to Garfield tables. These Garfield tables make a middling product which is treated on the 8 Wilfley tables, yielding a concentrate and a middling. The tailing from the Garfield and the middling from the Wilfley tables is returned to No. 3 elevator, whence it is delivered to four primary 4-spigot classifiers. The coarser sizes from No. 1 and 2 spigots are delivered to the feed tanks for the Chile mills. The third spigot product of the primary classifiers is delivered to two secondary 5-spigot classifiers; the fourth spigot of the primary classifiers being delivered to the other set of two secondary 5-spigot classifiers. The overflow from the 4-spigot primary classifiers is sent to the first set of 10 cone settling tanks, whence the thickened pulp is delivered to the smooth-belt vanners.

The product of the first four spigots of the set of secondary classifiers treating the third-spigot product of the primary classifiers is sent back to the proper Garfield tables. The fifth-spigot product is sent to corrugated-belt vanners, these yielding a tailing and a concentrate, the overflow going to a second and third set of cone settling tanks. The two secondary 5-spigot classifiers treating the fourth-spigot product of the primary classifiers deliver to separate corrugated-belt vanners, the overflow joining the other overflow from the 5-spigot classifiers and being taken to cone settling tanks, the thickened pulp being treated on smooth-belt vanners.

The material from the first and second spigot of the primary classifiers is re-ground in the Chile mills, which are equipped with ton-cap screens having a width of opening of approximately 0.04 in. This re-ground material is then delivered to two 3-spigot classifiers, known as mill classifiers. The first spigot of these classifiers delivers to the proper Garfield tables, yielding a middling and a tailing, as de-

scribed above, the middling being re-treated on Wilfleys and the tailing being returned to the system previously described. The second and third-spigot products are combined and treated on the proper Garfield tables, following the same circuit. The overflow from the mill classifiers is taken to a fourth set of cone settling tanks and the thickened pulp treated on vanners, making a concentrate and a tailing. Thus it will be seen that there is a closed circuit on the roughing system, the outlets being simply through the overflow from the classifiers, cone settling tanks, and through the fifth spigot of the set of secondary classifiers and five spigots of the second set of secondary classifiers through the corrugated-belt vanners, thus giving opportunity for the removal of the free mineral without unnecessary grinding.

The daily capacity of each unit of the mill has been demonstrated to be fully equal to that estimated in the beginning, namely, 1000 tons per day. While the present recoveries on the most oxidized ores lying immediately under the soil have not been high, the cost for the production of copper for the month of January was but slightly over 8c. per pound, with every probability that as additional sections of the mill come into operation and fresher ore is mined, this cost will be reduced.

Murex Process at Cordoba

The Cordoba Copper Co. was formed in 1908 as a consolidation of the companies operating the Cerro Muriano and North Cerro Muriano copper mines, 10 miles northeast of the city of Cordoba, in the south of Spain. John Taylor & Sons are the managers. The ore deposit is difficult to follow and work, and the smelting and concentration are not simple problems. The operations have been substantially extended during the past year or so, and much better results have been obtained. The amount of ore raised during the year ended September 30 last was 86,285 tons, as compared with 61,887 tons the year before, and the reserve has been increased by 66,495 tons, standing on September 30 at 199,398 tons, containing 3.59% copper; an increase in grade of 0.31%. The erection of converters designed by W. A. Heywood has been completed, and since September the output has been in the form of blister copper. Of the ore raised and treated at the company's own plant, 6630 tons was hand picked and sent direct to the smelter, 2240 tons of rich fine was screened and sent to the sintering pots, and 63,609 tons sent to the concentrators. The last produced 8238 tons of concentrate assaying 11.1% copper, which was sent to the sintering pots and briquetting machines; and 9455 tons of middling, assaying 1.47%, which was sent to the Murex plant, where 936 tons of concentrate was obtained averaging 12.2% copper. The remaining ore was hand picked and dressed by contract, and the products sent to the smelter and sintering departments. Owing to the sintering pots being worked to their maximum, other fine had to be treated by briquetting, the binding material being slime. The smelting plant treated 10,122 tons of picked ore, 7886 tons of sintered material, and 2427 tons of briquettes, and yielded 3439 tons of matte averaging 57% copper. By means of the wet concentrators and the Murex plant, the percentage of recovery is 75; the coarse tailing averages 0.65%, the fine tailing 1.17%, and the slime 1.53% copper. The magnetite used in the Murex process is not subsequently eliminated, because iron is required in smelting, and the magnetite in this case costs no more than hematite, which would have to be purchased in any case. The oil used is a thick coal-tar product, which, if any tar refinery were a customer for it, would be more valuable for that purpose than for selling to the Cordoba company. The tailing will be treated by the process in the course of a short time, and the recovery will then be greatly improved. The engineers of the Cordoba company express their appreciation of the process as applied.

PLATINUM DEPOSITS are said to have been discovered in Rio Grande del Sul, Brazil, but no definite information as to their value is yet available.

Mineral Losses in Gases and Fume

By F. G. COTTRELL

*In considering the mineral wastes passing out of the stacks of our smelters and metal refineries, distinction must be clearly made between the gases themselves and the clouds of suspended solid and liquid particles which they mechanically carry along with them. In which class a material belongs often depends, to be sure, on temperature. Many metallic compounds are actually vaporized in the furnaces and gradually condense from gases into clouds of solid particles with the progressive cooling of the gas streaming through the flues. Arsenic in the form of the trioxide is usually the last of these materials to condense, since even down to 150°C. its vapor tension is sufficient to permit the loss, in the gaseous state, of several tons per day for the largest plants. But below, say 125°C., for ordinary technical purposes it may be considered that the only important element in the gaseous state is sulphur, in the form of dioxide.

For many centuries the material nature of gases and the fact that they actually possess weight escaped the chemist. Even today a distinct effort of mind is required to sense the vast tonnage of the clouds to be seen floating away so lightly from smelter and power-house stacks. There are many single stacks in this country, from each of which over five tons of gas issued per minute, while in isolated instances this is exceeded several-fold.

Aside from carbon, the element which is lost in the greatest tonnage is unquestionably sulphur. Many of our Western ores will run from 25 to nearly 40% sulphur, and a plant smelting 1000 tons of ore per day is at present considered to have a very moderate capacity. The largest plants will easily touch the 1000 mark in tons of sulphur passing up their stacks when at full capacity. On stopping to think that this represents three thousand tons of concentrated sulphuric acid, were it made into such, and that one such plant could have supplied all the acid used in the whole phosphate industry of the United States a year ago, it is easier to appreciate the skepticism of the smelter companies regarding acid manufacture as a general solution of the sulphur fume problem. The disposal of this sulphur presents unquestionably the gravest problem confronting the metallurgical industry today.

Suggestions have not been wanting for methods of direct absorption of this gaseous sulphur dioxide by water, limestone, lime, or charcoal, either as a means of final disposal, or as a step in its concentration and final liquefaction under cold or pressure. One of the most ingenious and attractive is that it be used for decomposing fine granulated and moistened slag,¹ thus fixing the sulphur in harmless compounds and, at the same time, leaching out any metal still held in the slag. While many of these are perfectly practicable on a laboratory scale, the tonnage to be handled and the cost, either in first installation or operation, have prevented them from producing any practical results up to the present.

From a chemical standpoint, the other obvious alternatives consist either in oxidation to sulphuric acid or reduction to elementary sulphur. Of these two, the first has the advantage of requiring no additional substance save the oxygen of the air, and of running itself, when properly catalyzed, without need of external energy, but unless an immediate market is at hand for the sulphuric acid, its disposal in turn becomes difficult and often impossible.

The greatest consumption of sulphuric acid in this country today is in the manufacture of superphosphate fertilizer, but, until very recently, the chief demand for fertilizer has been in the Southern and Atlantic states; here, too, were the chief known deposits of phosphate rock, while, on the

other hand, the great smelting industry is for the most part in the far West, and cut off by high transportation costs. The recent discovery and description in Idaho, Wyoming, and Montana, of what promises to be the largest phosphate deposits in the world, will, it is hoped, materially change this condition.

Much of the land in the West is still practically virgin soil; where crops are falling off, the reason for this and their relations to different kinds of fertilizers to tillage and crop rotation, are still so much in dispute that in trying to build a rational and permanently helpful phosphate industry, the facts must first be thoroughly established from the standpoint of agriculture, manufacture, and transportation. At present, these are not available to any extent justifying an immediate general development of the phosphate industry in the West; but coöperative work, aimed at a broad and practical study of these conditions, is already well under way between the U. S. Department of Agriculture, the Agricultural Experiment Stations of various Western states, the U. S. Bureau of Mines, and the large metallurgical interests of the West, and it is hoped that the results may soon justify and lead to a healthy development of the industry.

An encouraging example is before us in the work already accomplished by the Tennessee Copper Co. at its plant at Copper Hill, Tennessee. This company is successfully treating the weak gases from copper blast-furnaces on a scale for which many predicted failure, and which certainly did require time, courage, ability, and indefatigable effort to perfect. The very difficulties and delays which the work had to encounter have in one sense been a help to the industry, as the present annual capacity of 250,000 tons of chamber acid has been gradually reached over a period of some years, and while it has materially reduced the price of acid in the South, the market has had a chance to adapt itself with the minimum of hardship to those already in the field, and with great gain to both the metallurgical and agricultural communities. Although much may undoubtedly be done, not only to increase the consumption of sulphuric acid in superphosphate manufacture, but also in developing other and newer uses, still the chemist should not rest content with this.

I have considered so far only the results of oxidation of the sulphur to dioxide. On the other hand, it may also be reduced to elementary sulphur, for which purpose a number of methods have been proposed, some depending on the action of solid carbon or of carbonaceous reducing gases, while others use hydrogen sulphide generated by the action of steam or acids on alkaline or metallic sulphides. An interesting general discussion both of the possibilities and the limitations of these methods together with some very suggestive new facts² has recently been attracting considerable attention and may not improbably lead to practical results, at least in certain special cases.

This naturally leads to the inquiry: "Why should all the sulphur of the ores be oxidized in the first place?" This question comes home still more forcibly on looking through the charge doors of a pyritic copper blast-furnace shortly after a fresh charge of ore has been dropped on the column and seeing the great clouds of unburned sulphur subliming out from the charge itself and burning above it, while all the heat thus produced is wasted. If copper blast-furnaces could be run with gas-tight tops, as is the case with iron blast-furnaces, and full utilization of the air blown in the lower part of the charge column, it certainly seems as though a far better thermal efficiency should be attainable, besides the possibility of delivering a very considerable proportion

*Abstract from the *Journal of Industrial Engineering & Chemistry*.

of the sulphur of the ore to the flue in unburned form, either as a gas or cloud of flowers of sulphur, depending on how cool the top of the ore column could be maintained.

That such a mode of operation is not entirely impossible is curiously evidenced by the fact that the first pyritic copper blast-furnace ever run³ was operated under these very conditions, the run finally terminating, after a few hours, by so much free sulphur accumulating in the flues as to stop the furnace. In this classic article of John Hollaway's, particular stress was laid upon the recovery of the sulphur, but the development of smelting practice soon began to follow other aims. It was naturally in the hands of the copper men, and sulphur did not so directly interest them. Then, too, in the far West, where pyritic smelting was first carried on successfully on the large scale and where even today probably 90% of it is still practised, the limited market for sulphur and the high cost of transportation and low value per ton, as compared with copper, have naturally influenced metallurgical development to strain for the greatest degree of economy in copper production, with absolute disregard for sulphur as a by-product.

In working the vast tonnage of low-grade sulphide ores of the West, effort is concentrated on burning out and slagging off the maximum amount of iron in the blast-furnace in order to produce as high a percentage of copper as possible in the resulting matte, as it is much more expensive to burn out a pound of iron in the converter than it is in the blast-furnace. This greater cost is due chiefly to two items; the cost of the refractory linings, and the greater power-consumption due to the higher pressure of air in the converter. Hollaway looked on his blast-furnace simply as a means of melting the ore into low-grade matte, the remaining iron of which might then be burned off in some of the then well-known processes or in a converter, which he was also the first to use in copper metallurgy.

In copper smelting, it has been the cost of converter practice which has led to crowding as much of the work of oxidation upon the blast-furnace as possible, and this insures the burning up of all the sulphur instead of recovering a good portion of it. Within the last few years, one of the two items of converter cost, that of linings, has been greatly reduced by the practical development of basic linings, so that today this factor is rapidly becoming almost negligible, and all that stands in the way of shifting most of the work of oxidation from the blast-furnace to the converter is the cost of the high-pressure air (10 to 15 lb. per square inch as against 3 lb. for blast-furnace) required to force its way in against the hydrostatic pressure of the deep liquid bath in the converter. If a mechanically more efficient way of mixing this air with the molten matte in the converter could be secured, it would mean the opening of a new chapter in metallurgy.

Even with the greater cost for air, the relation between blast-furnace and converter operations is already steadily changing in the sense of taking a lower-grade matte to the converters, and this in turn may be expected to react in a study of the blast-furnace from a somewhat different point of view than has hitherto obtained.

The copper blast-furnace is today confessedly one of the crudest appliances of engineering practice, and we know with less certainty the mechanics and chemistry of its inner workings than of almost any other apparatus of equal industrial importance. The slow development of a really fundamental scientific basis for this field of metallurgical engineering has undoubtedly been due in great part to the exceptional difficulty, if not impossibility, in this particular subject, of interpreting small-scale experiments in terms of full-scale operation, and the great expense of full-scale experiments.

Another reason for metallurgy having lagged behind other engineering branches is perhaps to be found in the fact that commercially it has usually been pursued as an

adjunct to the private ownership of some natural resource. If the mine were a rich one, the ultimate economies of smelting practice were apt to be overshadowed by the more immediately attractive study of increasing tonnage; if, on the contrary, the low grade of the ore made careful smelting necessary, the company felt it could seldom afford to go into expensive experiments for radical developments of the art, but must stay close to standard practice and make its improvements on minor details.

Even if elementary sulphur were produced, its present consumption outside of sulphuric acid manufacture is too small to be at all significant, but it at least has the advantage over acid of permitting safe accumulation and storage to an unlimited extent, as illustrated by the practice in Louisiana, where it is cast into blocks some 200 ft. square and 50 ft. high. What is really most needed for the solution of the sulphur fume problem is the discovery of new uses and a wider extension of existing uses for both elementary sulphur and sulphuric acid. Chemists have become accustomed to looking at sulphur almost exclusively from its chemical aspect, but if it is ever to be utilized in anything like the proportions in which it is now being thrown away, it would be well to consider possible mechanical uses, as, for example, a binder for sand or wood fibre. Experiments on the manufacture and use of drain tile made of such material are at present being carried out in the West, where the recent rapid development of irrigation is constantly bringing new and special demands for material of construction.

If metallic sulphides are dissolved in molten sulphur, its toughness and other mechanical properties are greatly improved, as first pointed out by J. B. Spence.⁴ A detailed study of this product from the standpoint of structural materials has long awaited the investigators and seems much to be desired. If a sufficiently large and permanent outlet for sulphuric acid, on the one hand, and elementary sulphur on the other, can be assured reasonably near the sources of supply, the metallurgical industry itself can be safely relied upon to meet the demands and find the way to supply them.

'Gopher-Holes' in Open-Cut Excavation

For economically excavating surface soil and hardpan in stripping operations, 'gopher-holes' have proved satisfactory. These holes were formerly made large enough for a man to crawl into and were dug by that manner. It was the custom to drive the hole into the side of a bank for perhaps 15 ft. and to turn two short cross-cuts at the end; black powder was then tamped in a depression in the end of each cross-cut. On account of the large amount of explosive which could be used, a very great lifting force was exerted and huge masses of the bank were broken.

On the Mesabi iron range in Minnesota, where stripping operations are conducted on a large scale, it has been found possible to dig these gopher-holes with a long-handled shovel similar to that used in digging telephone-post holes. By this means a smaller hole is dug and a saving effected in the cost per foot. Instead of the cross-cuts, a single depression is made at the end of the hole, in which the powder is securely tamped. Two styles of shovel are used in the process, one for the gopher-hole proper and one for making the depression at the end. Surprisingly low costs have resulted when the men became accustomed to manipulating the shovels.

COPPER REFINING in Australia is only performed at the plant of the Port Kembla Electrolytic Refining & Smelting Works, which is capable of treating 80 to 90 tons of copper per day. Since the smelting industry in Australia is not very extensive, much of the ore going abroad for treatment, it has been proposed to impose an export duty on ore, or to give a bonus on ore smelted in the Commonwealth.

The Surface Equipment of the Hancock Consolidated

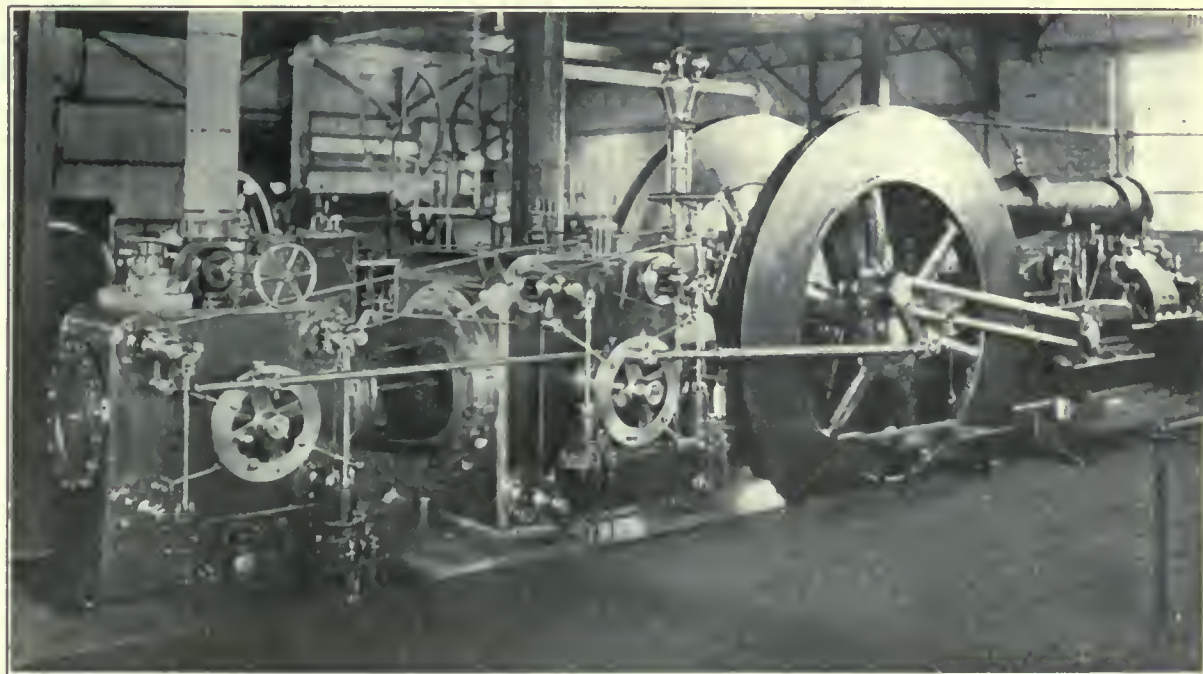

By W. P. PERKINS

*The Hancock Consolidated Mining Co., of Hancock, Michigan, has had in operation since March of 1911 what

6,000,000 lb. of copper was produced. At that time the mine was closed, owing to the low price then prevailing for copper. Twenty years later, in 1906, the Hancock Consolidated M. Co. was organized, with John D. Cuddihy as president, John L. Harris as general manager, and F. G. Schubert as superintendent. Operations were renewed in the old or No. 1 shaft, and in December 1906 ground was broken for shaft No. 2. This is a 5-compartment vertical shaft. Its outside dimensions are 9 by 30

SULLIVAN HOIST, HANCOCK CONSOLIDATED MINING CO.

STRAIGHT-LINE TWO-STAGE AIR-COMPRESSOR, HANCOCK CONSOLIDATED MINING CO.

is in many respects the most complete and modern surface equipment in the copper-mining district of northern Michigan.

The old Hancock mine was opened in 1859, in what is now the centre of the city of Hancock. These early workings, now known as shaft No. 1, extended to a depth of a little over 1000 ft. in the Sumner amygdaloidal beds. Work in this mine was carried on until 1886, and about

ft., and it is the second largest shaft in the Lake Superior district. It is now completed to a depth of 3300 ft., and its present objective point is the Pewabic lode, which it is expected will be found at a depth of 3600 ft. The shaft has a collar of solid concrete extending 40 ft. below the surface. This concrete is 24 in. thick at the top and 30 in. thick at the bottom.

The head-frame is a modern structure of steel, 128 ft. high, with the working-floor 64 ft. above the ground. There are two steel ore-bins 38 ft. in diameter, holding 900 tons

*Prepared with the assistance of F. G. Schubert and published also in *Mine and Quarry*.

of rock each. There are two crushers with a capacity of 1200 tons of ore per day. These crushers have jaws 24 by 36 in., and each is fed by a steel belt-conveyor 5 ft. wide and 17 ft. between the sprockets. The conveyors have a section with slots and cross-bars, giving an opening of 2 in. square to form a grizzly for small rock to pass through. The crushers are driven by 50-hp. motors and the conveyors by 10-hp. motors.

The boiler-house is built of steel and is 56 by 98 ft. floor space. It contains two batteries each, of four 150-hp. return tubular fire-tube boilers, each 72 in. diameter by 18 ft. long. Standard-gauge railroad coal-cars are run into the building and the coal dumped into bins directly in front of the boilers. The capacity of the bins is 250 tons. The stack is built of reinforced concrete and is 125 ft. high and 12 ft. 8 in. diam. at the base. The engine-house is also of steel, with a ground area of 60 by 94 ft., and contains the two hoisting plants. The three air-compressors are installed in a wing 50 by 50 ft. in area.

The first hoist installed for sinking purposes was a Sullivan first-motion double-drum Corliss plant, and has been in operation since 1906. This plant consists of two 24 by 48 reversible Corliss engines, operating through friction clutches two drums, each 8 ft. diameter by 6 ft. long. The drums are machine threaded. This plant has a capacity of hoisting from a depth of 4000 ft. at a speed of from 2000 to 2500 ft. per minute. Each drum handles two Kimberly skips in balance. The net load, exclusive of the weight of the rope, is 10,000 lb. This plant is now used as an auxiliary to the main plant, and ordinarily handles men and timbers only.

In 1910 a second or permanent hoisting plant was installed, also of Sullivan design and construction. This consists of two 36 by 72-in. simple Corliss reversing engines, which are keyed to the shaft of a 15 by 15-ft. straight-faced drum, machine threaded. This hoist operates two skips in balance and has a capacity of lifting eight tons of rock from a depth of 4000 ft. at a speed of 3500 ft. per minute. The cages have Kimberly skips swung under and weighing five tons. Both of these hoists exhaust into a 3000-hp. feed-water heater, which heats water to 190°; they take steam from the boiler plant at 150 lb. pressure.

Both hoists are equipped with safety appliances of the most improved pattern. These consist of an automatic throttle-closing device, by means of which the main throttles are closed automatically at a point in hoisting, previously determined, at which the mechanism is set to act. After this device goes into effect it is impossible for the engineer to open the main throttles until the engines have been reversed for the down trip. This mechanism relieves the engineer entirely of judgment as to the point in hoisting at which the throttles should be closed. For short movements of the skip, or in case varying load should cause the skip to come to a stop before reaching the dump or the level desired, small bypass throttles are provided which enable the engines to be turned over and bring the skip slowly to the desired point. In case the engineer should neglect to apply his brake at the proper point, after the throttles have been closed, an automatic brake is provided which goes into effect at a predetermined point before the landing is reached. This device absolutely prevents an over-wind, with the serious consequences which such an accident would entail. When this automatic brake goes into action it is impossible to release the brake or to move the hoist until the reverse lever has been thrown for the return trip. In the double-drum hoist there is a separate automatic throttle-closing device and automatic brake for each drum, so that each can act and be governed independently of the other. In this hoist the automatic brake is locked in position when set, by means of a blocking mechanism which must be released by hand before the engineer can move the hoist.

When operations were resumed in 1906 the company installed a Sullivan straight-line two-stage air-compressor with simple slide-valve steam cylinder controlled by Meyer ad-

justable cut-off. The steam cylinders are 22 by 24 inches in size, and the air cylinders 24 by 14½ by 24 in. The rated capacity is 1300 cu. ft. of free air per minute. This was used for shaft-sinking and development until 1910, when the company installed a Sullivan tandem Corliss compound two-stage air unit with a capacity of 2450 cu. ft. of free air per minute. The steam cylinders are 20 and 34 by 30 in.; air cylinders, 18 and 30 in., and have a 30-in. stroke.

The high and low-pressure steam cylinders of this compressor are equipped with full Corliss valve-gear, actuated by dash-pots, the point of cut-off being under the control of a speed and pressure regulator of simple design, which depends for its action on both the steam and terminal air-pressure. The air-inlet valves on both these units are of the semi-rotary Corliss pattern, actuated by independent eccentrics on the ends of the shaft. The air-discharge valves are of special automatic poppet design and are placed in the cylinder-head. They are simple in construction and easily moved. They can be removed for inspection and cleaning, together with their removable cages. The inter-cooling area in these machines is unusually large.

The compressor-house also contains a cross-compound Meyer valve-gear compressor with two-stage air cylinders, having a capacity of 1700 cu. ft. of free air per minute. All of these compressors are operated condensing. The Corliss tandem unit is connected to a jet condenser and the cross-compound machines with barometric condensers.

Canadian Silver Production

The silver production of Canada, which has been rapidly increasing during the past few years, will probably show but little change in 1911. Returns so far received appear to indicate a falling off of about 128,516 oz. The total production of the year is estimated at 32,740,748 oz., valued at \$17,452,128, of which 30,761,690 oz. was from Ontario, 1,910,323 oz. from British Columbia, 50,300 oz. from the Yukon, and 18,435 oz. from Quebec. The production in Ontario was slightly greater than that of the previous year, and in British Columbia a falling off of nearly half a million ounces is shown. For British Columbia the figures represent the recovery as silver bullion or silver contained in smelter products, while for Ontario the figures represent the total silver content of ore and concentrate shipped, less 5% allowed for smelter losses, together with bullion shipments.

The total shipments of ore and concentrate from the Cobalt district and adjacent mines were about 16,234 tons, containing approximately 28,817,198 oz., in addition to which 3,334,052 oz. was shipped as bullion. The average silver content of ore and concentrate shipped was thus about 1744 oz., or \$929.62 per ton, as compared with an average of 867 oz. in 1910 and 840 oz. in 1909. The 1911 shipments were chiefly high-grade ore averaging over 3400 oz. and concentrate averaging over 850 oz. The shipments in 1910 were 28,684 tons of ore containing 23,797,111 oz. of silver, or an average of 830 oz. per ton; 6943 tons of concentrate containing 7,111,579 oz., or an average of 1024 oz. per ton and bullion containing 1,003,111 fine ounces.

The exports of silver in ore, etc., as reported by the Customs Department were 31,216,725 oz., valued at \$15,807,366. There was also an importation of silver in bars, blocks, sheets, etc., valued at \$847,645.

GOLD-DREDGING in the Amur region is likely to show considerable expansion this season, following the recent discoveries along the Lyamur, according to a Russian report given in *The Mining Journal*. According to this report the Orsk Goldfields, Ltd., which has leased the properties of the Oelotsk company near Nikolaievsk, will build a power plant on the shore of Lake Shlya, about eight miles from the mining property, and will operate its dredges by electricity. Much interest is also exhibited in the Udy and Orel lake systems, and it is said that negotiations are under way for the sale of properties there to English firms.

The Nikko Copper Works

Among metallurgical plants in Japan visited by the American engineers last fall, none was more interesting than the copper refinery and wire works of the Furukawa company at Nikko. At this plant 1000 tons per month of wire is made, 600 from copper contained in the ore from the mines of the Furukawa company, of which the Ashio is the largest and best known,* and 400 from purchased ore. There is a rapidly growing market for copper wire in Japan, where interurban electric lines are beginning to be built, and where the dense population makes them certain of profit. Japan as yet produces a surplus of copper and this has been marketed in Europe and China principally. The Furukawa company, however, has been investigating the markets of Australia and India, where tariff laws favor importation of wire, with a view to exporting the finished material, and it is not to be expected that unfinished products will continue to be shipped.

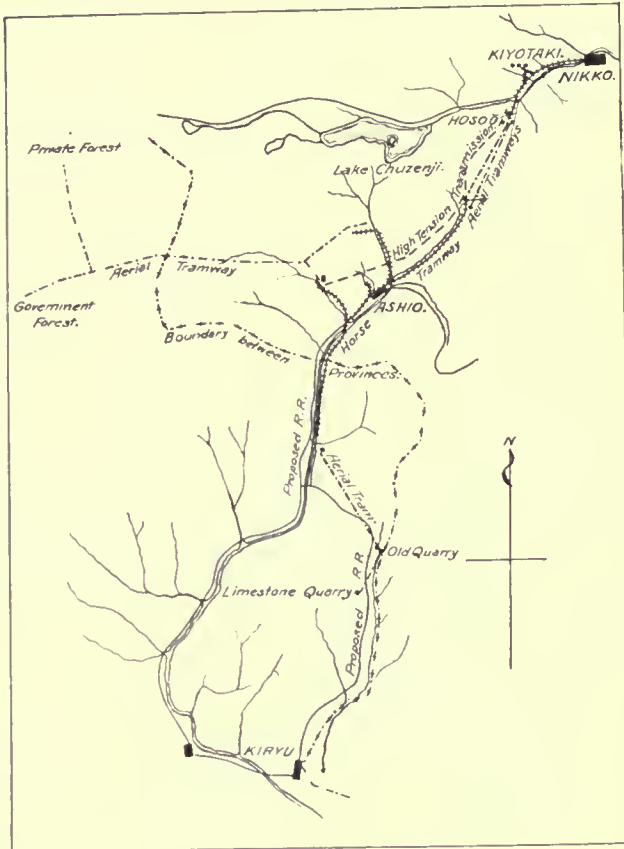

At the time of the visit of the American mining engineers, November 16, they were elaborately entertained at a luncheon at which M. Otagawa, managing director of the Furukawa company, in a felicitous speech, gave interesting details about the works and the copper industry of Japan. A copy of this speech having recently come to hand, it is printed, slightly condensed, below. Mr. Otagawa will be remembered in America as one of the commissioners from Japan at the Louisiana Purchase Exposition, where, as on the occasion of other visits to the United States, he made many friends among American engineers.

"Captain Hunt, Ladies, and Gentlemen: It is with much pleasure that I welcome you here on behalf of the Furukawa Mining Co., although I confess I am scarcely prepared to receive you in such a manner as I could wish, having been constantly on the pilgrimage with you since your arrival in Japan. It is a great satisfaction to us that you have ventured to come up to this part of the country when your departure is so near at hand. You are now in the heart of Japan, and you have already touched the hearts of the Japanese people. I trust you may find some attraction to compensate you for your journey here. As you already know, Nikko is renowned for its beautiful temples with majestic cryptomeria trees and romantic scenery, and I feel that our copper works are not worthy to be included in the category of Nikko's attractions.

"It is a pleasure to say that in copper mining and metallurgy we owe a vast deal to you Americans and particularly to your American Institute of Mining Engineers. Our copper works and copper mines are modeled after the gigantic works in your country. Dr. Raymond was kind enough to remark in his eloquent address at the luncheon given by the Mayor of Tokyo, that the bessemer converters adopted at Ashio were perhaps second only to those of Butte in date of introduction. Again, the plant for the series process of electrolytic refining here is one of the only three at present existing in the world; namely, one at the Nichols copper works, Laurel Hill, New York; another at the Baltimore copper works; and the third at our own works here. Another interesting fact may be mentioned in this connection, that the Nichols and the Baltimore copper works produce one-third of the total output of the world's electrolytic copper, while the Nikko copper works is credited with one-third of the electrolytic copper production of Japan. Japan ranks third after the United States and Mexico in copper production, and it is most gratifying to have here as our guests the representatives of the two greatest copper-producing countries in the world. We have followed the American way, and I assure you we are proud to be called the 'Yankees of the East.' The success of our copper works, however, has not been attained by mere imitation, but also by individ-

ual achievement. It is built on men. Besides trying to adopt things suitable for our purpose from America and Europe, we have made it our aim to originate, or at any rate to adapt things to meet our own conditions. We have always had competent men at the helm; men who have received a systematic education and training. K. Yamaguchi, former general manager, is an American product, being a graduate of Johns Hopkins University at Baltimore. He built the copper works. K. Okumura, present general manager, expects soon to double the output by the completion of a multiple-process plant.

"Copper mining in Japan is an ancient industry, and the metallurgy of copper reached a state of remarkable advancement in Japan in the old days. As early as the year 708, copper coins were minted in Japan, and our people have been acquainted, from time almost immemorial, with a smelting process called *mabuki* which presents an

SURFACE MAP, ASHIO MINE.

interesting analogy to the present bessemer process. During my stay in New York in 1906, when I was asked to write an article on Japanese copper in 'Mineral Industry,' I think I started it with *Roshana-Butsu*, that huge image of Buddha we saw last week at Nara. This gigantic bronze statue was erected between 743 and 752. The finish and workmanship may serve as an illustration of the advanced state of our copper industry over twelve centuries ago. Moreover, Japan seems to have given a considerable amount of attention to mining even earlier. In the days of Marco Polo, Japan was known in Europe as 'the Island of Gold and Silver,' and the famous voyager informed the West that there was a palace in Japan, roofed with golden tiles, the ceilings made of the precious metal and spangled with gold and silver ornaments. So valuable, indeed, the riches of the palace were supposed to be, that it was one of the attractions to Christopher Columbus, who desired to reach *Zipangu* (Japan) on his voyage of discovery. While this report was greatly exaggerated, you will see tomorrow the Toshogu temples, in the decoration of which silver and gold are lavishly employed. The copper tiles, with which the temples as well as the castle in Tokyo are roofed, all came from the Ashio mines. Japan's copper industry has always been in a prosperous condition, and over 300 years ago Japanese copper was exported to Europe through the agency of the Dutch."

*The Ashio Copper Mine,' T. T. Read, *Mining and Scientific Press*, October 14, 1911.

Titanium and Its Uses

By H. M. HENTON

*Titanium belongs to the fourth group in the periodic system, next after carbon in the sub-group with zirconium, cerium, and thorium. In many of its properties it is closely allied to silicon, in the other division of the same group. It unites with oxygen and the halogens like silicon, and is more active than carbon in its reaction with nitrogen. The proportions in these combinations vary, corresponding to valences 2, 3, and 4, according to the oxidizing or reducing quality of the surrounding bath. Titanium and carbon also react to form the carbide and, together with nitrogen, form the cyanide. These are the properties which make the element of such importance in the iron and steel world. It never occurs in the free state and is only reduced to the metallic state under the most exacting conditions.

The ores of titanium are rutile; brookite; octahedrite (all different forms of the oxide); titanite, or CaTiSiO_5 ; ilmenite; titaniferous magnetite; and various iron and calcium silicates of minor importance. As a constituent of rocks it is one of the most widely distributed elements of the earth's surface. The titaniferous iron ores occur in all parts of the world, great masses being present in Norway, Sweden, and Canada, in North Carolina, and the Adirondack mountains in New York. Rutile occurs mainly in Virginia, Norway, and Australia. Georgia, North Carolina, Maine, and New York have smaller deposits.

The production of rutile is limited to two districts, one in Norway, and the other in Nelson county, Virginia. The Kragerö, Norway, deposit produces 50 tons of pure titanium oxide annually. The Virginia rutile beds are worked by the General Electric Co. and the American Rutile Co., and produced 86 tons of concentrate in 1910. A 95% concentrate sells for about \$190 per ton, and the 75 to 80% for \$80 per ton. Ilmenite, containing 14 to 45% TiO_2 , when concentrated to 60% brings \$40 per ton. The alloy ferro-titanium, containing 10 to 14% of the element, is now used extensively in the manufacture of the best grades of iron and steel for all purposes and sells for \$365 per ton. The most of this alloy used is made by the Titanium Alloy Co. of Pittsburg under patents of A. J. Rossi, who was a pioneer in the long struggle for the recognition of titanium as a slag-former and remover of impurities in the making of iron and steel.

High-titanium ilmenites are reduced with carbon in the electric furnace, producing a high-carbon alloy useful in the cleansing of pig iron. An ore containing 15% TiO_2 can be treated with a small amount of carbon, just enough to reduce the iron, and limestone, yielding a slag concentrated in titanium to 56 to 58%, and a pig iron of best quality. The slag concentrate can be reduced in an aluminum bath in the furnace, utilizing the heat of formation of Al_2O_3 . Here the iron is reduced first, then the titanium. The latter, though of higher melting point, dissolves in the molten iron, forming a true alloy of 10 to 75% titanium and 12 to 75% carbon. This product is diluted with iron according to the percentage desired, and is practically carbon free.

These ores were once discarded, and as late as 1907 it was thought by the conservative metallurgists that as low as 2% titanium was objectionable. All the trouble with pasty slag, aggregations of nitrides and cyanides, and excessive fuel required, have vanished as fast as the operators have been induced to figure on the TiO_2 in the charge. An excessive quantity of lime, formerly used, threw the titanium all to the calcium titanate, an infusible compound. Now, a much smaller quantity of flux is used, causing instead the formation of calcium titano-silicate. This is easily fusible at blast-furnace temperatures, making possible a good pig iron and a fluid slag from ores containing 20% TiO_2 .

The pig iron in which titanium was originally present or

introduced during the making, has a much greater crushing strength on account of the removal of occluded gases and the prevention of segregation. The titanium, when introduced, cannot be used in the form of the element because the melting point is too high, the specific gravity too low, and the cost of the metal prohibitive. As only a small amount is needed, generally the addition comes to about 0.5% in the form of the ferro-titanium alloy. It meets the requirements in every particular, actually increasing the fluidity of the slag instead of decreasing it, as was formerly supposed. Used in machinery pig iron, the castings become closer-grained and stronger. In car-wheels the depth of chill is greatly increased. In copper castings there is a similar beneficial action. The copper-titanium alloy is not as cheap as the iron alloy, however.

In steel-making, titanium fills a varied sphere of usefulness. It is used in bessemer and open-hearth processes, acid and basic, and in the crucible process. The general practice is to add the pulverized cold alloy, just as the steel runs into the ladle, after the recarburization and introduction of spiegel and ferro-silicon, allowing time enough for its complete dissemination through the whole mass. The nitrogen, of which 0.03% renders a hard steel brittle and useless, is taken up as Ti_2N_3 and TiN_2 , which form at a temperature of 800°C. Carbon, phosphorus, and sulphur are removed, to a large extent, partly by chemical combination and partly by a sort of physical concentration of the occluded gases around the pipe cavity of the ingot. The dreaded blow-holes are eliminated entirely from the body of the steel if the heat has been normally treated in the blowing. The titanium compounds have a lower specific gravity than the steel, so rise to the surface in a slag, all the oxides being reduced by the active titanium. It is claimed by some that the latter adds the toughening and hardening qualities noticed in titanium steel by virtue of constituent titanium retained in the steel, but the consensus of opinion seems to be that its only effect is due to its purifying action upon the metal.

The rail steel thus treated works better in the rolling mill, wears better, and the output includes less second grade. All steels, up to the most refined, used for instruments and tools, are profitably improved by the addition of this cleanser. When silicon can be added a very serviceable alloy, titanio-silicon, is available. It is made by melting together in the electric furnace suitable proportions of TiO_2 and clean white sand. Over 97% of the special steel rails manufactured in 1910 were titanium steel. This is largely because of the successful abrasion, ductility, endurance, corrosion, tensile, and drop tests made in 1909. There is some demand for titanium in electrodes for arc lamps. Two forms are efficient, copper-plated titanium carbide, and the magnesite-titanium modification. Patents have been issued to cover its use in electric glow lamps, claiming a high candle-power efficiency. A little is used in pottery and for coloring glass.

GREAT BRITAIN is much further along in organization of mine-rescue work than is the United States. It was recently announced that plans now in the making involved a mine-rescue station not farther than 15 miles from any colliery in Great Britain. Men trained in rescue work receive certificates and when they have been 'under fire' receive medals. For each accident at which they have been on duty they are given service bars. Recently more than 40 bars were presented as a result of one explosion. While at Briceville, Tennessee, not more than 20, only in part trained men, were available for the new rescue work.

REFINED COPPER is not produced in Canada to any extent, and the output is represented by the copper content of smelter products, matte, and blister copper produced, together with the amount of copper contained in ores exported estimated as recoverable. The total production on this basis in 1911 was 55,848,665 lb., valued at \$6,911,831, as compared with 55,692,369 lb., valued at \$7,094,094 in 1910.

*Abstract from *The Pahasapa Quarterly*.

Alaska and the Yukon

By GUY A. R. LEWINGTON

At this time when so much interest is manifested in Alaska and there are such wide differences of opinion as to what its needs really are, it may not be amiss to make better known the conditions that exist just across the boundary line in the Yukon Territory, which many believe is a part of Alaska. Conditions in general in central Alaska and the Klondike are practically the same. The Klondike region, with Dawson as the central point, is under Canadian authority, while all Alaska is governed by the United States Congress without actual representation. The Yukon has its regular member of Parliament, its own wholly elective local council, and to all intents

a grant, except on authority of the Attorney General of Canada, representing the lessor, and to secure his consent to begin such suit he must be clearly shown that the contestant has sound legal reasons. Such suits are practically unknown. Quartz and other mineral claims (placer and coal excepted) may be 'Crown granted', or patented as in the States, and are under the leasing system until such time as the required amount of work has been accomplished to entitle them to patent. To secure patent to a mineral claim it must be conclusively shown that at least \$500 has been expended in improvements and that the claim has been properly surveyed and advertised for a period of 60 days in the nearest newspaper. The required annual assessment work is \$100, and upon affidavit to the effect that the work has been done, which work is subjected to Governmental inspection, a certificate of work is issued which entitles the holder to an extension of his

MAP OF ALASKA.

governs itself. The Government long ago realized that a territory larger by far than any other in Canada could not be satisfactorily administered from Ottawa, and it wisely placed the reins in the hands of the people who work and live in the Territory. The mining code which has been in operation since 1907 cannot be amended except by act of Parliament, which means that before the code can be altered in any way, the people will have time to express their opinions either for or against such a change. It is difficult to conceive a more liberal law than the one in force in the Yukon. Regardless of nationality, and without restriction, any man or woman over 18 years of age may locate either placer, quartz, coal, or any other mineral claim, and may hold it as securely as may native-born Canadians. Placer claims are leased by the Government to the applicant for the sum of \$10 per annum, payable in advance, which insures absolute title, since only one grant can be issued for the same piece of ground for the year in which it is in force, and upon compulsory affidavit covering necessary assessment work made at the expiration of the grant, or annual lease, a renewal is issued for another year.

Under this system the litigation which has been, and still is, the curse of Alaska is not possible; 'jumping' is unknown, and no suit can be brought against the holder of

lease for one year. The survey of the claim may be sworn in as assessment work for the year in which it is done. The lessee of a mineral claim, upon securing five certificates of work representing \$500, one of which may be for surveying, may apply for a patent by submitting the five certificates of work to the proper authority. An order is then issued by the Government permitting the holder or lessee to have his claim advertised, and, upon completion of the advertising and payment of \$1 for each acre contained in the claim, also some minor office fees, and in case no adverse claim has been recorded prior to the expiration of the advertising period, a certificate of improvements is given. This certificate is equivalent to a patent, and the claim is then withdrawn from the public lands. No further work on the part of the owner is necessary, and the patent itself is issued in due time. The whole operation is simplicity itself, and makes the 'red tape' necessary in Alaska seem ridiculous.

Coal may be located by the placing of one stake, which may hold from 1 to 2560 acres for each individual applicant, who secured his lease in much the same manner as a placer miner. If his location is open for entry, he is given a lease for 21 years with the privilege of renewal if he has lived up to the requirements of his lease. The Government charges him \$1 per annum rental for each

acre in his claim. He is also compelled to mine from 1 to 10 tons of coal per acre per annum (number of tons at the discretion of the Minister of the Interior), and when he begins to market his coal 5 cents per ton royalty is collected for all merchantable coal. Under this law it is not feasible to hold large tracts indefinitely for speculation. The law is doubtless hard in some respects, but it prevents grabbing, which is one of the principal aims.

Those who are planning for Alaska's future needs may well study the laws in force in the Yukon Territory. Alaska needs laws adaptable to Alaska, not to Arizona or any other part of the United States. Why not give Alaska a code of her own, just as Yukon has one of her own? During the past summer, delegations of United States senators and other influential Government officials paid hurried visits to the southeastern coast, or fringe, of Alaska, and went away with the idea that they were in possession of facts covering the country. As a matter of fact, they saw only the extreme edge and listened to the wants of the people there. The information they secured was purely local and not valuable when the requirements of all Alaska are considered. From personal experience, I know that one visiting the southern coast line only can have no conception of the magnificent country lying behind the great barrier range for hundreds of miles straight north. The climate of the south coast is the most disagreeable in Alaska, not even excepting Point Barrow, the northernmost point of the continent.

The Yukon Territory is now (February) having what is usually the most severe weather, but there is nothing disagreeable about it. Citizens of Dawson read reports of extreme cold at outside points, of people freezing to death, while there they go about whatever has to be done without particular discomfort. Toronto reports 25° below zero, which degree of cold at Dawson is considered by all delightful weather. Children of all ages may be seen rolling around in the snow, having the time of their lives. They are of course warmly dressed, but they can be out, play, thrive, and come to no harm, even at 35° below zero. They continue going to school even in the coldest weather. On the night of February 15 an open-air dance was held on the public school grounds at which 1500 people of Dawson were present, and they enjoyed every minute of it. On-lookers wore their fur coats, but the dancers wore sweaters, short skirts, and moccasins. The dancing was on the snow, packed hard by the feet of the school-children in their various games. At the same moment the people of Toronto and other cities in Canada and the States were closely housed on account of the extremely severe weather. It must not be supposed that the winters are for the most part moderate. On the contrary, it is probable that no colder weather is experienced anywhere. Temperatures as low as 60° and even 70° below zero occur with striking regularity for short periods of each winter; this, however, causes no great hardship, as it is expected and provided for. People remain a little closer at home, realizing no discomfort, much as they do in stormy weather outside. A study of the isothermal lines will be found most interesting.

The foregoing, it is hoped, will give some idea of the interior of Alaska, as well as that of the Klondike, as a place where people live in comfort carrying on their daily vocations much as they do in other cold climates which are closer in touch with the Great Outside, and consequently better understood. Alaska needs immediate, adequate, and radical legislation. It is not reasonable to suppose that laws adapted to the States will apply equally well to a country so far removed from the seat of government, where practically all conditions are different. No man can know Alaska or its needs by a journey along its coast. He must traverse it and bump up against some of its difficulties, which are not met during a pleasant summer tour on comparatively comfortable river steamers and at equally good hotels. If Alaska's law-makers were better versed in the requirements of the country, judicious legislation might be expected, and Alaska would soon come into her own and develop beyond belief. Give her just and applicable laws,

allowing her to pass judgment on them before becoming final, and she will do the rest. As before mentioned, a study of what Canada has done for the Yukon Territory and a close examination into the leasing system in vogue here, which practically eliminates litigation, the greatest curse of Alaska, cannot fail to help those who have the welfare of Alaska at heart.

Taviche

By AN OCCASIONAL CONTRIBUTOR

The mining district of Taviche is near the southern end of the National Railways of Mexico, about 35 miles south of the city of Oaxaca, capital of the state of the same name. The altitude is about 6000 feet and the climate probably the best on the continent. The rainfall last year was 17 inches, but this is probably less than usual. Rains begin in May and last until October. The country rock is andesite, occurring in at least three flows, and in some places brecciated. No sedimentary rock is in evidence.

The veins have a general northwest direction, and a variable dip, from vertical, as in the San Juan mine, to 30° southeast, as in the San Francisco mine. The vein filling is quartz, but in some instances the country rock has been crushed, silicified, and mineralized. Sometimes the veins have a selvage, varying from a few inches to two or more feet, and barren. A vertical and horizontal movement has taken place along the vein, and great pressure is shown, but there appears to have been but little displacement. Some cross-faulting is shown, but in no case so far discovered has this exceeded 20 ft. Ore occurs from the surface and, so far as present evidence shows, the best ore is passed at 400 ft. and the content gradually decreases from this point until at about 700 ft. the vein becomes too poor to work. The latest developments in the San Juan mine would tend to disprove this theory, but this is the one exception so far discovered. The veins vary in width from a few inches, as in the Baldomero, to 50 ft. in the Conejo Blanco. The ore throughout the district will average about 5 ft. in width. With the exception of the Conejo Blanco mine, the assay values are more in silver than gold; in the Escuadra the ore will carry 3 parts gold to 1000 silver; in the San Juan, 12 parts gold to 1000 silver, and in the San Francisco, 10 parts gold to 1000 silver, all by weight. The Conejo Blanco mine is the richest in gold and will average 30 gold to 1000 silver. The entire ore of the district is very silicious, an average analysis being about 75% insoluble, with small amounts of sulphur and iron, and in some cases as high as 10% zinc. The silver occurs as both the light and dark ruby silver, with some brittle silver, and the gold is in some way associated with these minerals. Free gold seldom occurs.

The economic conditions, with the exception of the great distance from supplies, are good. A fair grade of oak wood costs \$3 to \$5 per cord, American coal \$16 per ton, and native charcoal can be had for \$7, delivered at the mine. Wood and charcoal can only be had in limited quantities, and the price will vary with the season. For operation on a large scale, coal or oil is the only fuel that could be considered. Water is scarce, and within the district the total surface flow will not exceed 20,000 gal. per day during the dry season. Most of the mines are comparatively dry; the three produce, when working, over 35,000 gal. per day. The great disadvantage is the long haul and the necessary high freight rate to the smelters. The present freight and treatment at Aguascalientes is \$20. The only solution to the low-grade ore problem appears to be the erection of a suitable plant on the ground, and, from numerous tests, fine grinding and cyaniding alone will produce satisfactory results. Labor is inefficient but cheap, and the cost per ton of operating is, if anything, lower than elsewhere in Mexico. To get the best results, all work should be done by contract. Miners will average 50c. to 75c., timbermen 75c., engineers \$1. and laborers 32c. per day. The production of the district has been in the neighborhood of \$10,000 gross, and while reliable data are lacking, this figure appears a safe estimate.

Potash Salts in Southern California

Press Bulletin of the U. S. Geological Survey.

The two Federal bureaus engaged in the search for potash salts, the Bureau of Soils of the Department of Agriculture and the Geological Survey of the Department of the Interior, have received promising telegraphic news from their field representatives. A potash deposit of apparently great importance has been discovered in Borax or Searles lake, in the northwestern corner of San Bernardino county, California. This lake or *playa* is the last remaining pocket of a once much greater lake which has almost dried up, and its central depression contains a large body of crystalline salts known to consist of common salt and sulphate and carbonate of soda, with small quantities of borax. This salt body is saturated with brine, and interested persons, stimulated by the governmental search for potash, recently secured an analysis of old sample material from this brine. The result being significant, the lake was visited jointly by representatives of the Geological Survey and of the Bureau of Soils who took brine samples from six wells distributed over the salt flat. Analyses of these samples have been made by the coöperative laboratory at the Mackay School of Mines, at Reno, Nevada, and show an average of 6.78% of potassium oxide (K_2O) contained. The average salinity of the brine is 43.82 grams of solids per 100 c.c. Comparison of the results indicates that the brines are nearly uniform throughout the flat. The probable importance of the deposit is due to the occurrence of the potassium salts in soluble form in a natural saturated brine, and under climatic and other conditions especially favorable to its separation and recovery by solar evaporation. Existing data give reasonable assurance that the brine-saturated salt body is at least 60 ft. thick and covers an area of at least eleven square miles. Assuming the salt body to contain 25% by volume of the brine, the total amount of potassium oxide is estimated at over 4,000,000 short tons. This estimate is believed to be conservative, and the available tonnage may well be expected to exceed 10,000,000 tons, which would supply the country, at the present rate of consumption of potash, for thirty years. At any rate, it appears that this locality constitutes a very important source of potash in probably readily available commercial form. Methods of separating potash from brines are now under investigation by the Bureau of Soils.

Borax lake or Searles lake is one of the many *playas* or intermittently wet and dry lakes common throughout the arid regions of the West. It lies between the Argus and Slate ranges, in the Mohave desert of southern California. Borax lake was the original scene of the famous "20-mule-team" borax mine, the borax being hauled in great wagons drawn by 20 to 28 big mules to the Southern Pacific railroad at Mohave, a distance of 80 miles. The lake or flat is about 10 miles long and 5 miles wide and has received the drainage from the surrounding hills for many thousands of years, vast quantities of dissolved minerals being thus concentrated in it. The water has been evaporated under the intense heat of the long hot seasons, but the salts have remained, so that for most of the year—in fact, often throughout the year—the bed is a glistening plain of white salts, in attempting to cross which men have lost their lives. Borings have been made through the mud and water underlying the lake to a depth of some hundreds of feet, the deepest borings made bringing up hot mud.

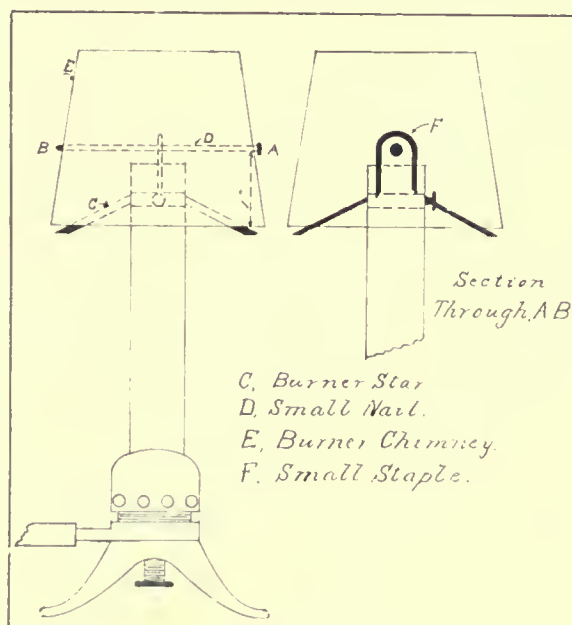

Many useful and curious minerals are found in the muds and other deposits of Borax lake, including, of course, borax. Among them are gypsum, glauberite, carbonate and sulphate of soda, salt, thenardite, and hanksite. The last carries as much as 2.33% of potassium, equivalent to 4.44% of potassium chloride. The salts are not evenly distributed over the surface of the lake. Borax was found plentifully over about three square miles, common salt is everywhere, and sodium carbonate and sodium sulphate are widely distributed. One boring is said to have passed through 28 ft. of solid trona (hydrous carbonate of soda) of great purity. At other places there is 25 ft. of solid

mixed sulphate and carbonate of soda, with smaller quantities of other salts. Although the lake bed is dry most of the time, a few inches under the outer crust there is always water—a bittern heavily impregnated with salts. Several years ago an English company attempted to work the soda deposits on an extensive scale, but for some reason the work has not been pushed. This company sunk a number of wells, easing them through the soda deposits. It was found that a heavy stream of water could be pumped continuously without perceptibly lowering the water-level. Potassium chloride and sulphate, the forms in which potash salts are most likely to be found in such deposits, are among the most soluble of salts and are likely to be much more generally diffused than salts less easily soluble. That the entire body of water and mud in the lake contains potash in a more or less uniform degree, is indicated by the results thus far attained. However, there are modifying agencies, such as springs and streams, that bring in fresh water, for the movement of water through the lake will be slow, owing to the presence of the sand and salts.

A Substitute for the Blast-Lamp

By W. A. ERNST

The chemist often requires a flame which is hotter than the flame from an ordinary bunsen burner. He can, of course, resort to the blast-lamp, but blast-lamps are not available in many laboratories, and the chemist is obliged to make use of the foot bellows, which is inconvenient and cumbersome. On looking around for some method by which a hotter flame could be produced by the ordinary

C, Burner Star
D, Small Wail.
E, Burner Chimney.
F, Small Staple.

SUBSTITUTE FOR A BLAST-LAMP.

bunsen burner, I discovered that by making a simple change in the chimney for a bunsen burner, an intensely hot flame, almost equal to the blast-lamp, could be produced. This flame will be found sufficient for all ordinary purposes, such as making fusions and ignitions. The accompanying diagram is self-explanatory. A small wire nail is inserted one inch above the bottom of the burner chimney, and a small wire or staple hung over the nail; this is allowed to go part way into the burner. The height which the nail and staple must be from the burner must be found for each individual lamp, but can be regulated by moving the chimney up or down by the aid of the burner star. When once the proper height is obtained, all that is necessary to convert the bunsen into a blast-lamp is to turn on the full force of the gas. An ordinary flame can be maintained with the chimney in position, by simply reducing the flow of gas. The best results will be obtained if the nail and staple are kept well within the inner cone of the flame.—*Jour. Ind. & Eng. Chem.*

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Is 'Cheap' Labor Economical?

The Editor:

Sir—Having had nearly seven years of continuous experience with Filipino labor in connection with mining and milling in the Philippine Islands, I venture to offer the following remarks regarding its efficiency and possibilities, in response to the invitation extended in your editorial on cheap labor. I quite agree with Wickham Quinlan that the mass of untrained Filipinos are essentially children, and that they have the possibility inherent in them of becoming good workmen. In lines requiring manual dexterity they rapidly become efficient under proper supervision.

Practically all of my experience has been with the Filipino of the provinces. During the early days there were practically no natives outside of Manila that had any training in mining work, as, previous to the American occupation, very little mining had been done in the Islands. The use of powder in mining was practically unknown, except in a limited way in the Camarines. In the Benguet district the Igorotes had 'gophered' for many years. When the Americans came, the Igorotes were employed (and are still) in prospecting and assessment work, their pay being 50c. conant* per day and 'chow'. When given contracts for assessment work they were paid from ₱5 to ₱7 per chipa (this being the span from finger-tip to finger-tip of a fair-sized native). I have had adits in rock hard enough to stand up safely, but not requiring powder, driven for ₱50 for the first 100 ft. When it came to regular operations, the Igorotes were found to be too undependable, however, and it became necessary to bring in Filipinos from the neighboring coast provinces of Pangasinan, La Union, and others. Some of these had had previous experience in powder and rock work on the Benguet road, and quickly became fairly good miners. They brought their families along, and settled down at the mines, and proved to be steady and reliable. When there was any scarcity in labor, these people sent for their friends and relatives, so the supply was kept up, and I can only say that after the first importation there were never any but temporary shortages in labor while I was in this district. The wages paid (₱1 per day with rations, or ₱1.20 without) proved sufficiently attractive to bring the best class of labor from the lowlands to the mines.

One mine in this district employed a few experienced Japanese miners to good advantage, using them mostly as timbermen and hard rock men, and paying them from ₱2 to ₱2.50 per day. Native timbermen were paid ₱1.20 per day with 'chow', and *capitases* ₱1.40 to ₱1.50. Since I left here two years ago, the rates have gone up about 20c. conant all around, but are not high, considering that the men receiving them have become more experienced. The rates paid in the Camarines have, I believe, been somewhat higher than those given above, but the grade of the labor there was better to begin with. In the Aroroy district, Island of Masbate, the base rate for miners is a peso per day without chow; that of common labor being 80c. conant. Timbermen receive ₱1.20 and *capitases* ₱1.50 without chow. The efficiency of the labor there is not nearly so high as in Benguet, owing largely to the fact that it is recruited mostly from the Visayans of the surrounding country, and partly to difference in climatic conditions. The best men in that district have been brought in from Benguet and the Camarines. These imported men come to mine, and have no other interests to interfere.

*50c. conant = 25c. gold.

The local laborer works at the mines at times when crops have been planted and fishing is poor, or when he needs a little ready money.

I have found, both in Benguet and Aroroy, that one of the best incentives to work for the native is to run a well stocked company store where he can get rid of his money and at the same time get something that adds to his comfort and welfare—in other words, to increase his wants by providing what he needs. When the native once gets a start he is very fond of good clothes, and will buy the best. It has often been remarked in Baguio that a man who has been at the mines very long can be picked out by the superiority of his dress. A tailor was employed in connection with the company store at one mine in the district.

It is a very difficult matter to establish any exact ratio of efficiency between men of different races working under such different conditions as exist here and at home, but I shall nevertheless try to fix such approximate ratios as appear to me to exist, using that of an average miner in the West as 100%. On this basis, I would regard that of a native miner in Benguet, after having had six months experience, at 33⅓% and that of a miner of similar experience at Aroroy at 25%. In timber work, their percentages would drop somewhat, owing to lack of previous training of the natives and their comparatively small stature (average height being about 5 ft. 4 in., weight about 130 lb.). The efficiency of a common laborer in Benguet I would put at 25% and in Aroroy at 20%. In all cases, it must be understood that the labor has proper and capable supervision, and that no comparison is attempted between the native and the white working under the same conditions. The white man could not do the work of a native in this climate and stand up under it, so it is fortunate that it is not necessary.

In milling work, where quickness and dexterity come more into play, I have found that native boys break in quickly, and in this work I would place the relative efficiency at 40% as compared with the average mill-hand without special training. For this work the smaller and younger men are the best, being more alert. It is necessary to avoid giving each boy too much to look after and to have good supervision to keep them up to the mark. Granting these, I would as soon operate with a good bunch of native boys as the average lot of millmen of equivalent experience at home. When it comes to lines requiring special mechanical training, it is yet necessary to draw on Manila. Good native machinists can be hired for provincial work at from ₱75 to ₱90 per month, and in efficiency the work of these men would be from 40 to 50% of that of white machinists. Engineers get from ₱50 to ₱60 per month, and firemen from ₱35 to ₱40, all without chow. The efficiency of the latter is about the same as with machinists.

The general conclusion may be drawn with respect to labor in these Islands that the *efficiency increases with proper training faster than the rate of wages*. This makes the outlook, with a liberal supply of raw material to draw upon, very promising, provided that the people are not misled by agitators. I regard the policy of the present Government in providing liberally for the education of the native, especially in industrial lines, a very wise one. It has been my experience that the boys who have been to school and speak English are quicker to learn and more ambitious than those fresh from the *bosque*. For timber construction and mine-timber framing I have always employed Japanese carpenters, for the reason that they are very efficient and accurate. The Filipino is as yet lacking in skill in carpentering and smithing, but the schools are giving instruction along these lines, and the natives working with the Japanese as helpers are learning slowly, so it may be possible to eliminate the Japanese carpenter after a while, except for the finer work on construction.

Altogether, the labor situation (upon which everything here depends) is not so bad as has been painted, and it will continue to improve, if those in charge of industries here will do the right thing and make the necessary effort to improve the quality of the work and look out for the

personal welfare of their employees. Nowhere is scientific management more necessary.

C. M. EYE.

Baguio, Philippine Islands, February 4.

Laboratory Cyanide Tests

The Editor:

Sir—The question of long-pipe percolators in making cyanide extraction tests, as discussed by George A. James in your issue of December 30, 1911, and by A. W. Allen, February 17, 1912, is interesting. As more and more rebellious ores are being treated by the cyanide process, the question of laboratory tests and the appliances for making them becomes of increasing importance. The tall iron-pipe percolator has been used in this country, but I have never seen it so conveniently arranged as Mr. Allen sug-

CONVENIENT AGITATION APPARATUS.

gests, with the easily separated flange couplings. It seems to me that it is not alone the determination of the leaching rate that makes the pipe percolator useful. For instance, if the leaching rate is so rapid that an unnecessarily large amount of solution would have to be passed to the zinc-boxes, the leaching rate can be cut down at the valve and the effect on the solution noted. An examination of the effluent solution from a deep charge of ore often reveals important facts. If the effluent solution is in proper condition, little uneasiness need be felt as to the extraction in the lower portion of the vat. I have always considered it quite important to keep a percolation test leaching continuously where there is the least danger of the solution becoming too low in protective alkali or picking up alkaline sulphides to a considerable extent during its passage through the charge. The test can conveniently be kept leaching through the entire night by filling a can with solution and inverting it over the percolator after the manner of the flask suggested by Mr. James. However, the greater part of the work can usually be done by agitation tests, and on account of the large number that may be run simultaneously with little outlay for equipment, I think they are to be preferred, using the percolator tests as a final check rather than the principal method. Of course, everybody makes 'bottle tests,' but they are too often regarded as a rather unimportant preliminary. In making the so-called bottle tests, too small a quantity of material is usually taken.

The agitation apparatus I prefer to use consists of a wooden disc rotating at a speed of not more than 5 to 8 r.p.m., the shaft being set at such an angle that the axis of rotation will coincide with the hypotenuse of a right triangle whose vertical altitude is 1 and its base 2. The top of the disc is provided with sheet-steel clips to removably hold six or more two-quart (half-gallon) Mason fruit jars, the bottoms of the jars resting flat upon the disc. Enough solution can be used in this apparatus to make zinc-dust precipitation practicable, and in case separate treatment of sand and slime is contemplated they need not be separated in the earlier stages of the work. The tests can be put on the agitator near the close of the day, run during the night, and will generally be ready for assay in the morning, thus making it possible to turn off a con-

siderable amount of work in a short time and with little labor. By means of this apparatus I once determined with a fair degree of accuracy what might be expected to happen in the bottom of a deep, slowly leaching charge, by filling the jar full, sealing it with the cap, and titrating the solution at intervals. Of course, in making a test of this kind, due account must be taken of the relatively large amount of solution in the agitator. For instance, if the ratio of solution to ore is 5 to 1, and the voids between the grains of sand in the leaching-vat would allow the vat charge to consist of 50% solution (a ratio of 1 to 1), then whatever changes are found in the solution at the end of the test should be multiplied by 5. I do not know how I could have determined this point by means of the usual quart percolators used in this class of work.

It is perhaps needless to add that in making tests upon coarsely crushed material, either the half-gallon jars or ordinary glass percolators are liable to lead one considerably astray on account of the poor sampling which inevitably results. A convenient and easily remembered rule for the size of test samples is to square the diameter of the largest grains, measured in sixteenths of an inch. The result will be the number of pounds of ordinary mill rock that should be taken to accord with good sampling practice. For instance, if the stuff is crushed to a $\frac{5}{16}$ -in. screen opening, 25 lb. would be sufficient, but if the screen opening is $\frac{7}{16}$, the amount required would be, in round numbers, 50 pounds.

JOHN RANDALL.

Gold Deposited by Magnetic Electric Currents

The Editor:

Sir—The letter from F. J. Martin and your comments thereon in the *Mining and Scientific Press*, February 24, are quite interesting.

Since magnetic effects are static, Mr. Martin evidently means electric currents rather than 'magnetic currents.' In practical electrical work the earth is conceived to be always at zero potential and to have infinite conductivity. However, that applies only to parts near the surface and is not always true under desert conditions. Below the water-level, where the rocks are dry, the electrical resistance is high except along such lines of conducting material as are found in the water channels in fissures. It does not seem likely that deep-seated earth movements would be able to produce sufficient differences of potential over large areas to allow appreciable electric currents to flow to the surface. The movement of conducting solutions across the earth's magnetic field would produce local currents. These would be very small, because their potential would depend on the velocity of movement, which is comparatively slow.

A more important electrical effect would be found in the galvanic action taking place between dissimilar metals after they begin to deposit. Thus if a particle of gold and a particle of pyrite be precipitated in such a way that they touch at some point, a current will at once flow from gold to pyrite and back through the solution to gold. Gold would be deposited on the gold particle and pyrite would be redissolved. Since pyrite is nearly always in excess, the tendency would be to precipitate all the gold in the adjacent solution. Hence Mr. Martin's idea that electric currents have something to do with the coarseness of the gold is probably right. Experiments along these lines would be interesting.

Tin Dredging in Alaska

The Editor:

Sir—In your issue of January 6, T. M. Gibson, in discussing 'Tin Dredging on Cape York, Alaska', states that W. W. Johnson and his associates have all of the property on Buck creek. This is not strictly true, as I, myself, have No. 5 on this creek and have not leased it to anyone.

LYDIA R. CLEMENTS.

Brookline, Massachusetts, March 14.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

ANTIMONY is not produced commercially in the United States at present, except in the form of hard lead, and about 5000 tons of the metal is imported annually. China and France are the chief producing countries.

SMALL dams to store water should be provided with a gate through which accumulated silt and sand may be flushed out from time to time, otherwise the area back of the dam may become almost completely filled by it.

ANCIENT river beds in California sometimes lie as much as 3000 ft. above the modern streams which have cut their channels below. This is especially true along the American river, near the eastern end of Forest Hill divide, near Canada hill, and at Bald mountain.

TAILING which runs upon the land of another may be claimed by the owner of the land; or he may claim damages, if injured by it. Near Bodie, California, ranch-owners allow the working of old tailing which has accumulated upon their land, upon a royalty basis.

ORE-BINS with inclined bottoms give a smaller angle of repose to the contained ore, which therefore runs more freely when the gate is opened. An angle of 45° is the most convenient to construct and approximates the angle theoretically deduced for ordinary classes of ore.

DITCH-OWNERS are responsible for damages due to washouts, even though they are not due to negligence. An 'act of God,' such as a storm, does not free the ditch-owner from responsibility for the damage sustained by another from the overflow of a ditch from such a cause.

THERE is a general impression that Japan is a large producer of antimony, probably derived from the remarkable crystallized specimens of stibnite from Shikoku, which can be seen in almost every mineralogical museum. But the commercial production of antimony in Japan is not large.

BLACK-PRINT papers have recently come into use. They show black lines on a white ground and are printed and washed just as blue-print papers are. These papers cost from two to three times as much as ordinary blue-print paper. A direct blue-line paper is also made, but it requires three washings like brown-print paper.

TIMBER for a two-compartment shaft, 5 by 11 ft. in the clear, will amount to about 1000 board feet per set. This includes heavy timbers and all blocking and lagging as well. The length of time required to put a set in place depends on the character and condition of the ground and the experience of the men. Ordinarily a set can be erected quicker in an inclined than in a vertical shaft.

EXPERIMENTS undertaken for measuring the temperature on the inner surface of the cylinder of a small gas-engine have shown that the temperature is about 465° F., and that the variation from cycle to cycle is usually less than 18° F. The steady conditions of low temperature at the wall surface are caused by the jacket water, while great changes of temperature take place at a short distance from the walls.

THE most efficient grade for tables and sluices is considered to be 1½ in. per foot. The quantity of water used in washing gravel varies considerably and depends a great deal upon the amount and character of the material washed, as well as on the personal judgment of the op-

erator. There are, probably, few cases in which the exact quantity of water used has been determined. Some operators claim they do not use more than 100 in., while others claim to use an average of 300 inches.

LITMUS paper, when used to detect the acidity or alkalinity of solutions, may give variable results, according to the method of its preparation, the amount of salts present in the paper, and the character of the paper itself. To make a good blue paper 1.4% of chemically pure litmus is dissolved in distilled water with continued shaking for about one hour. The solution is allowed to stand over night, is carefully decanted from the sediment, and H₂SO₄ added, drop by drop, until the alkalinity is reduced to the point where a piece of paper made from the solution will assume a perceptible red color when placed for a half minute in N/2000 HCl. To make red litmus a 10% solution is required, and H₂SO₄ is added until paper made from the solution will show a distinct blue color with N/4000 caustic soda solution.

UNUSUAL elements present in gold and silver ores can often be detected by the colors which they impart to the cupel near the finished button. When bismuth is present the place which the silver button occupies is brown, surrounded by concentric rings of yellow and blackish green. Copper colors the cupel a dirty green to black, according to the amount present. Nickel leaves a greenish ring of scoria, while arsenic, antimony, zinc, and tin give a light colored ring of scoria if present in large amounts. Ruthenium imparts a peculiar greenish tinge to the cupel, and the other metals of platinum also color the cupel, but as usually several of the group are present at the same time, it is difficult to determine whether the color observed is due to a single element, or the combined effect of several. These metals may carry iron into the lead bullion, with the resulting formation of a great variety of colors on the cupel. Where appreciable amounts of the platinum group metals are present their presence can often be detected by the appearance of the silver button, to which platinum gives a rough and pitted look, while palladium makes the surface appear raised and embossed. Osmium makes the button have a rough surface and break up, ruthenium produces a black film, while iridosmium makes the surface of the bead look as though it were covered with bright, flat, silvery plates or crystals.

APPLICATION for permit to cut timber without charge in accordance with the Act of Congress providing for the reasonable use of timber on public land, must be presented or mailed to the register and receiver of the local land office, or the Chief of Field Division having jurisdiction over the land, who will supply application forms upon request. The application must set forth the names and legal residences of persons applying to fell and remove timber, names and residences of persons who are to use the timber, amount of timber required for each person, and the use to be made thereof, date it is desired to begin cutting, and description of land to be cut over. No timber may be cut for sale or transported from or used out of the state in which it is cut. Persons who commence cutting before their permits receive the final approval of the Commissioner of the General Land Office, will be liable for a reasonable stumpage if the permits are not approved. Where permits are secured by fraud, or immature trees are taken, or timber is not used or taken in accordance with the terms of the law, the Government will enforce civil and criminal liabilities as in other cases of timber trespass upon public land. These may range from the stumpage value of the timber cut in the case of an unintentional trespass to the value of the timber where found, and a fine not exceeding \$500; to which may be added imprisonment for six months, in case of wilful and malicious timber trespass. There is no authorization to cut any small or limited amount of timber under this act without a permit. The Government, of course, has not jurisdiction over the timber on patented claims or land.

NEW YORK

THE COPPER MARKET, PRESENT AND FUTURE.—GREENE-CANANEA EXPANSION.—OHIO COPPER.—INCREASE IN LA ROSE DIVIDENDS.—THE ELIMINATION OF STILLWELL.

So far as the copper market is concerned, there is no doubt as to its strengthened position, at least of the controlling interests. There is much more concentrated financial strength behind the copper-metal market than there was five years ago. John D. Ryan and his co-workers, who have been prophesying and working for a 15c. copper market, have found themselves so far successful as to see copper, May and June deliveries, sold at this price this week. The war clouds have saved the copper situation, and the new production, which threatened to increase an already overgrown surplus, can be absorbed now for a time without creating any burden. It is unquestionably true that many ordinary demands for copper are not being supplied now, and these accumulated requirements will, when conditions permit, take a vast quantity of copper, in much the same manner as an accumulated short interest takes stock out of a market when covering begins. As to the new production and its proportions, the next ninety days should reveal about what may be expected. Old properties have been rebuilt and ore reserves developed during the period of depression; the Lake country has been making some new mines, in the Ahmeek, the Lake, and others; Greene-Cananea and the old Arizona Copper Co. have been rebuilding; the Granby is ready to make a new start; and what may be done by these and properties in similar position, together with the porphyries, will be the controlling factor in copper during the next half-year.

With all of the upbuilding of the copper-metal market, there is a concerted movement to distribute stocks. Amalgamated Copper is probably to increase its dividend, hitherto \$2 per year, to \$3 or \$4 per year. The distribution of Anaconda shares in the Butte Coalition treasury is just being made, and as Amalgamated was a large holder of Coalition, it now receives a large block of Anaconda stock and a large amount of cash. The public is to be coaxed into 'Copper' again, if possible. In Wall Street slang, 'Copper' is the term for Amalgamated. With the exception, however, of this one issue, the copper-share list does not reflect the improved conditions in the metal market. The Greene-Cananea company evidently is not seriously disturbed by the Mexican uprisings. The company has recently secured control of the Superior Bonanza Mining Co., a property lying about 35-miles south of Nogales, in Sonora. The reason for the purchase is to secure a supply of oxide ores and so get a better flux.

It is thought that there is some deal afoot for the Ohio Copper Co. Henry Krumb has been spending the past two weeks in making an examination of the property, but in whose behalf is not yet known. The Utah Copper people deny that they are interested in any way—a denial which might be reasonably expected so long as E. A. Wall has anything to do with Ohio. Ohio is showing a small profit now from its operations. The United Copper Co. and the La France Copper Co., both Heinze organizations, are evidently approaching reorganization. The stockholders are being solicited for proxies. The Lexington Mines Co. is to be formed to take over the La France by purchase of its properties at foreclosure sale. The charter of the United Copper Co., which is organized under the laws of the state of New Jersey, has been forfeited for non-payment of taxes and, while the statement has been made that shareholders would be fully protected against any consequences, the conditions are cited as additional reasons for the shareholders to come to the rescue.

The Palmer Mountain Tunnel & Power Co. is to be reorganized. This company was floated throughout New England, and has thousands of small shareholders. The properties are at Loomis, Washington, and the project

was a rather large one. The shares were at one time sold above par, but dwindled to practically nothing. The reorganization will be, perforce, a very drastic one, and the company will practically make a new start. One bank in the far Northwest was wrecked by loans made to the company, and the president of that institution avoided a ten-year sentence in the penitentiary by 'jumping bail' and remaining outside of the jurisdiction.

The attention directed to the La Rose company by the resignation of E. P. Earle, because his associates on the Board refused to distribute the company's surplus in dividends, evidently had its effect upon the remaining members, as the dividend has been increased from 2% quarterly to 2½% quarterly. The stock is now upon a 10% basis. The new directors elected to the Board are: Edwin Hanson, of Montreal, and W. M. Dohell, of Quebec. It is said that A. E. Stillwell is to be eliminated from the Kansas City, Mexico & Orient railroad, which is about to go through reorganization. Mr. Stillwell has been an energetic and efficient promoter throughout the Southwest, but has apparently never been admitted to the inner circle

OHIO COPPER CO. MILL.

of financiers in New York. His recent book on the so-called 'Money Trusts' is thought to have placed him outside the pale. It may be taken as certain that New York banking interests will not assist him. Samuel Untermyer has charge of the reorganization plans, acting in behalf of the bondholders committee.

GLOBE, ARIZONA

SIXTEEN-INCH CHURN-DRILL TO BE TRIED IN DISTRICT.—BARNEY HOLE NO. 1 DOWN 1355 FEET.

The South Live Oak Development Co., holding under option the Schultze group of 16 claims adjoining the Montezuma and Needles groups, is preparing to begin exploration with churn-drills. Harry Millard, who will have charge of the drilling, has gone to St. Louis to purchase a 'St. Louis' churn-drill, made by the St. Louis Machine & Tool Co. It will have a 58-ft. derrick, with boiler and engine separate from the rig, and is designed for deep drilling. Holes will be started with a 16-in. bit, which is two inches larger than the largest size now in use in the district.

Hole No. 2, of the Southwestern Miami Development Co., cut chalcocite ore at a depth of 945 ft. and penetrated it 40 ft., being 985 ft. deep. Assay returns are not available. The 4½-in. tools and casing are now being used, and chances are considered favorable to reaching the bottom of the orebody with this hole. Hole No. 1 had to be abandoned while still in ore, after passing through 175 ft. of it. Hole No. 3 is 305 ft. deep, and still in the schist formation. Hole No. 1, on the Barney group, is down 1355 ft. and is still in the heavily iron-stained silicified schist in which it has been for the last 255 ft. This is the deepest hole ever drilled in the district, breaking the record of 1285 ft. made in Hole No. 1 at the Southwestern Miami. The 3-in. casing is being put in, and E. B. Tinker, the superintendent, expects to attain a depth of at least 1500 ft. Hole No. 2 is 300 ft. deep.

At the Inspiration mine, the experimental mill has been temporarily closed down to make some changes preparatory to starting another series of tests. The work on the dam across Pinal creek has been delayed by the recent rains and consequent high water. The Sho Me group of seven claims, south of and adjoining the claims of the Inspiration company, is being developed by Cleve W. Van Dyke, president of the Miami Townsite Co. A shaft 165 ft. deep is reported to have from two to four feet of ore carrying native copper. The shaft is now being cleaned out and repaired. A second shaft has been started on the Sho Me No. 2 claim, but has been delayed by the recent rains. The retimbering of the Copper Hill shaft of the Arizona Commercial company has been completed for a distance of 210 ft. below the collar. The Duquesne group is being worked by John Shaw with a force of five men. The last shipment, of 36 tons, assayed 1.02 oz. in gold and about 10% lead, and netted over \$17 per ton above freight and smelter charges.

BUTTE, MONTANA

TUOLUMNE SHOWS LARGE SURPLUS.—WASHOE SMELTER BREAKS RECORD.—GENERAL NOTES.

The Tuolumne Copper M. Co., listed on the Boston exchange a short time ago, which is among the independent companies of this city making an excellent showing, held its annual meeting a short while ago. The reports submitted were of a gratifying character, both as to the condition of the mine and of the treasury. Edward Hickey, president of the company, stated that there was no indebtedness and that there was a balance in the treasury at the end of the year of \$63,345, although the company has erected a complete new surface equipment and constructed a spur from the mine to connect with the Butte, Anaconda & Pacific railroad. The amount milled during the year was 30,499,009 tons of ore, containing 4,261,705 lb. copper, 96,373.15 oz. silver, and 145.52 oz. gold. The average copper content of the ore for the year was 7.157%, and the average silver content 3.237 oz. The gross value of these metals was \$472,943, and the net value was \$261,448. During the past year the working shaft of three compartments was sunk 177 ft., cross-cuts were run on the various levels a total distance of 1362 ft., and raises have been sunk totaling a depth of 866 ft. altogether. The shaft was sunk from the 1600-ft. level to a depth of about 1800 ft. On this level one of the finest orebodies yet found in the mine was uncovered. Samples recently taken show that four feet of this vein assays 12.7% copper, 13.4 oz. silver, and 60c. gold. Six feet of the vein shows assays of 5.95% copper, 5.8 oz. silver, and 14c. gold per ton, while two feet shows 3.75% copper, 2.6 oz. silver, and 8c. gold, with 13 ft. of lower-grade ore. No shipments have yet been made from this body of ore, and the reason for this is that the ventilation is bad on that level, and in order to remedy this, arrangements have been made with the North Butte company to connect with openings of the latter company.

The La France company does not want to again have to redeem its Basin Reduction Works property, if there is any way out of it. The Jefferson county authorities assessed the property last year at what was considered a fair valuation, but which the company considered too high. The taxes were unpaid at the close of the fiscal year, and the county officials took steps to enforce the collection through the courts. A stipulation has been filed in the Federal court that if the company pays \$17,500 in full settlement by May 1, no further proceedings will be taken, but if not paid by that date, a judgment will be taken in favor of the county. The Washoe smelter of the Anaconda company is making record work just now in turning out copper, and extra ore-trains are being run from this city to Anaconda to keep the works supplied. The production last month was the heaviest by the Anaconda company in the past two years, notwithstanding that it was the shortest month in the year. This month probably will exceed February by fully 1,000,000 lb. It was thought when the official figures for January showed 26,350,000 lb., that

the limit had been reached, but the February figures were announced at 27,450,000 lb. In the figures mentioned, the North Butte and Tuolumne productions are included, but the latter do not amount to over 2,750,000 lb. copper.

SALT LAKE CITY, UTAH

ANNUAL REPORT OF THE DALY-JUDGE.—SMELTING AT TINTIC.—PETROLEUM POSSIBILITIES OF UTAH.—WORK OF THE ASSAY OFFICE.

Among the grist of annual reports coming out at this time, that of the Daly-Judge Mining Co. of Park City is especially interesting as showing financial methods which might well become more popular among mining companies. The Daly-Judge is carrying a reserve of \$431,620, all of which is bearing interest. Instead of paying out dividends close to the margin of profit or keeping an idle reserve, this company has been steadily building up a large reserve and has been investing most of it in first-class securities. The greater part is invested in bonds and mortgages which bear a good rate of interest and can be realized upon at any time. In 1911 the surplus earned \$18,838 in interest; more than enough to pay the drainage expenses. This fund was increased \$115,404 in 1911, although regular dividends were resumed at the close of the year. The mine is now paying regularly at the rate of \$180,000 per year. The Daly-Judge has always had a zinc problem and a drainage problem. The latter was solved by making a connection with the Ontario drainage adit within the past year, so that development at depth is now under way, the workings being extended to the 2300-ft. level. The zinc problem has been handled satisfactorily for several years.

Plans are being made to resume operation at the Knight smelter at Tintic by summer. Whether or not Jesse Knight will be able to carry out his purpose successfully remains undetermined, but he is anxious to get some returns on his investment of about \$1,000,000, which has been idle for some time. The Knight interests control the Colorado, Iron Blossom, Swansea Consolidated, and other properties in the Tintic district. A few years ago, as a result of a dispute with the Guggenheims over smelting contracts, they decided to build a smelter of their own near Silver City. Other interests joined them at the outset, but eventually practically everybody dropped out except the Knights. The construction and operation of the plant were beset with vicissitudes. The operations were never profitable. This was attributable to various causes, among them the difficulty of getting fuel to the plant at a low enough figure. After several changes of management, the plant was shut down and the Knights contracted their ores to the United States and American plants. When the International entered the field, negotiations were undertaken for the Knight smelter, but no agreement as to price could be reached, so the million dollars' worth of buildings and machinery have lain idle. Now it is understood that better fuel conditions exist, and another effort is contemplated to get the plant into operation again.

Utah has been trembling on the verge of an oil boom at intervals for many years, although it has never had a genuine excitement, and now there is another set of preliminary symptoms. In many parts of the state there are unusually favorable oil indications, but only in the San Juan region, in the extreme southeastern part of the state, has there been anything like thorough prospecting. There the drilling has resulted in bringing in several wells, but the distance from a railroad and the limited amount of flow have kept the district from coming forward as much as it might under favorable transportation conditions. Drilling near Salt Lake City at two different periods has resulted in opening up numerous gas pockets, but the formation has been found to be too badly broken to offer great encouragement for petroleum in quantities. Drilling in the Virgin river region and elsewhere in the southern part of the state resulted similarly. The region south of Green River, Utah, especially in the San Rafael country in Emery county, has recently begun to attract the atten-

tion of experienced oil men, and several drilling operations are under way. Interests represented by Charles P. Tasker of Philadelphia have secured a large area in this district, have built a road 25 miles from Green River to the site of their first well, and are now shipping in a standard rig to begin drilling.

The Salt Lake U. S. Assay Office has shown a slight but steady increase in business since it was established. From February 1, 1909, to February 1, 1910, the receipts were \$1,151,000, and for 1911 the bullion handled amounted to \$1,300,000. The placing of an assay office here has made a material saving for the gold producers of the region, who would otherwise have to ship to Denver or San Francisco.

JOPLIN, MISSOURI

PRICE OF ZINC ORE HIGHEST SINCE 1905.—NEW SMELTER TO BE BUILT BY GRANBY MINING & SMELTING CO.—MIAMI DRAINAGE PROBLEM TROUBLESOME.—ZINC AND LEAD NOTES.

March 1912 saw the highest prices paid for zinc ore since 1905, when the basis figure for lots carrying 60% metallic zinc rose to \$57 per ton, meaning a top price of \$60 for choicer lots. The 1912 price went to \$55.50 basis, with a top price of \$58.50 for choicer lots, the highest price ever paid, with the single exception of 1905. As a result, production jumped, within a week, from 3400 tons to 5000 tons, and a week later the district was turning out 5600 tons of zincblende concentrate weekly. Several circumstances combined to strengthen the market. Locally the production was at low ebb, due chiefly to an unusually severe winter which caused many mines to close. Roads had been in bad condition and isolated producers found it difficult to transport their output to the railroads. Bad weather in other districts, especially in those of the Far West, caused a curtailment of zinc ores from other districts; in Mexico the revolution resulted in an almost total discontinuance of zinc-ore importations to the United States; so, in the face of this combination of features, smelters were forced to strengthen their offerings materially. In a single week, zinc ore went from \$49 to \$55.50 basis. Spelter, East St. Louis quotations, reached the highest price on record, going to \$7, although in 1907 metal went to \$7.25. New York quotations, East St. Louis spelter at that time, however, went only to \$6.90. Following the high prices, offerings weakened slowly. Blende dropped to a \$50 level toward the close of the month; metal, East St. Louis, fell to \$6.50. So far the aggregate valuation of the 1912 ore shipments is much greater than that of 1911, and, despite the fact that it is election year, the chances seem bright for 1912 eclipsing all previous years in total ore valuation.

One of the most modern zinc-smelting plants in the United States is to be built by the Granby Mining & Smelting Co. at Rose Lake, Illinois, a suburb of East St. Louis. Ground for this plant was purchased several years ago, but it was not until the recent meeting of the board of directors of the company that final decision concerning the size and cost of the plant was reached. Work is to be rushed. At the meeting, the financial report was submitted, showing a year of great prosperity, both in the smelting and mining departments. The company operates mines and leases lands for mining purposes in Joplin, Oronogo, Granby, and Spring City, all in Missouri. Elias S. Gatch was re-elected president.

Water is being lowered at the rate of one foot per week at the L. C. Church mines, Miami, Oklahoma, and this means that the water-level throughout the greater portion of the Miami district is being lowered at a proportionate rate. The pumps are working at a depth of 250 ft. Enormous pumps, installed in the deep mine of Chapman & Lennan, adjoining the Church property, will soon be running and will aid materially in the draining of the deeper ore-levels. With the opening of the lower ore-levels, Miami has taken a new lease on life. No less than 12 shafts have reached the new deep-ore formation, and when the

water problem is satisfactorily solved, extensive development of this lower run may be looked for. Already the Church mill is working on the deep ore. Chapman & Lennan are moving the Red Dog plant from the Rochester Zinc & Lead Co.'s lease, north of Webb City, Missouri, to Miami, and other new mills are contemplated. In addition to these plants, more than a dozen mills of the district, now handling shallow ores, may eventually be expected to work on the deeper deposits, as the opening and blocking out of the formation has been general, both with shafts and drill-holes.

North of Carl Junction, Missouri, in a region heretofore given over exclusively to farming and stock raising, extensive development is following in the wake of the mineral development at the Weaver mine, which is turning out as high as 350,000 lb. of high-grade concentrate weekly. A shaft is being started on an adjoining lease by E. M. Bennett and others who have put down a number of drill-holes and found ore. Half a dozen other drill rigs are working within a radius of two miles. About two years ago, workmen, in blasting holes for the concrete pillars of a bridge to span a small stream, unearthed specimens of pure galena. Immediately several gougers took leases on neighboring lands, and shallow shafts were sunk into rich pockets of lead ore, found at varying depths. The McFeran mine was the first producer, galena being the only ore turned out. Deeper work revealed big deposits of sphalerite, the present workings of the Weaver mine being at 172 feet.

To work thin ground profitably is the problem which the Diplomat Mining Co., of Galena, Kansas, is solving. The company believes in heavy milling capacity, and will double the present capacity of 500 tons per shift. The old Cimarron mill has been bought and will be moved to the Diplomat lease, where it will be re-erected and remodeled.

JOHANNESBURG, TRANSVAAL

FICTITIOUS HIGH RECORD FOR JANUARY.—POWER SUPPLY PROBLEMS.—RESUMPTION OF WORK AT PRIVATE PLANTS.—INCREASED SUPPLY.

Although the declared output of gold for the Transvaal for January by the Chamber of Mines constitutes another record and one probably that it will take some time to surpass, there are several outstanding features which may perhaps be regarded as detracting somewhat from its merits. The figures declared were 737,060 oz. of gold of a value of £3,130,830. The previous best output declared was that for the month of November, amounting to 719,729 oz. of a value of £3,057,213, so that the month of January apparently exceeds that of November by 17,331 oz. and £73,617 in value. As a matter of fact, the actual production of gold was less in January than that declared for November, as the East Rand Proprietary Mines and the New Kleinfontein discontinued, at the wish of shareholders, the policy of keeping a gold reserve and by this means added 18,764 oz. of gold belonging to previous months to the output declared for January, while several other companies also took liberally from their gold reserve to include in the January output. When this reserve gold is deducted from the January output as declared, it is only 715,159 oz., of a value of \$3,039,500. Another disappointing feature is the reduction in the estimated working profits, those for January being less than for a long time past, despite the increased declaration of gold for that month. All the groups except the Barnato & Consolidated Mines Selection show a fall in the estimated profits from a total of £864,758 to £809,649, the latter being the lowest reached for a good many months if the short month of February is not taken into consideration. This decline of working profits accompanying a growing total output of gold has been a noticeable feature in connection with the Rand gold-mining industry for some time past, and only a drastic reduction in the working costs would appear capable of bringing about the much-needed improvement in this respect.

There is no marked improvement in the condition of affairs regarding the supply of power in uniform and ample quantities to the mines by the Victoria Falls & Transvaal Power Co. Some surprise seems to be expressed that in face of the fact that the power company has got all its generating stations at work on the Rand, the consumption of coal should continue to increase in the same normal manner as before electrical power was introduced in the gold mines. There would appear to be two explanations for this; firstly, the power stations themselves use large quantities of coal; and secondly, the failure of the Victoria Falls Power company to keep up the supply of power, more especially compressed air, has caused many of the steam plants to be again put to work. Owing to the scarcity of native labor, the use of compressed air in the mines has considerably increased of late, and of course any failure of the Power company to supply the power stipulated according to its contract has to be made up by the mines at the expense of the Power company. For instance, one of the groups here used power in its mines during January costing £32,000, but in the shape of penalties and extra cost incurred in obtaining the necessary power, the group had a contra account of practically one-half that amount to deduct, so that for the power supplied, only one-half would be paid to the company for the power used. Supposing we take the cost per unit at 0.56d., it means that the Power company would receive payment at the rate of 0.28d. per unit, which under the local conditions can scarcely be considered a remunerative figure. Still, that is the position, and it would be interesting to know when affairs may be expected to be put on a better footing. The Victoria Falls Power company is at present engaged in erecting an additional generating station at Vereeniging, some thirty miles to the south of Johannesburg, which when completed will be on a much larger scale than the others, in the hope that along with other extensions to existing stations it will enable the Power company to fulfill its obligations to the mines. It may be that these troubles will explain the delay in starting operations in connection with the proposed station at Tweefontein, and it is to be hoped that the steps now being taken to increase the supply of power to the mines will be successful. Otherwise it may become necessary for the whole business to undergo some important changes, as it becomes increasingly difficult to see how, if operated on present lines, it can become a success.

LONDON

SUBSTITUTES FOR COAL.—DIESEL OIL ENGINES FOR MARINE USE.—PROSPEROUS NUNDYDROOG AND ITS ROSY OUTLOOK.—A SLUMP IN NIGERIAN SHARES.—IMPROVED TONE OF MARKET.

The present coal strike affords promoters an opportunity of offering investors a speculation in some sort of fuel, and the daily press has advertised several such. One company is called Coal Substitute, Ltd. The capital is £100,000 and 140,000 shares of 10s. each are being offered for subscription. The purchase price paid to the vendors is £65,000 in shares and cash. No mention is made in the prospectus as to the actual nature of the fuel, but it is stated to be produced in the form of briquettes that have been made in brick-making presses and kiln dried. The raw material comes from Portugal and 30,000,000 tons per annum can be delivered at Lisbon. No coal or peat is contained in the fuel. Sulman & Picard report that it contains 45.8% fixed carbon, 45.65% volatile hydrocarbons and combined moisture, and 7.55% ash. The sulphur content is 0.69%, contained partly in the fixed carbon and partly in the volatile constituents. The calorific power is reported to compare well with coal of average quality. H. Brian Pearson, who is on the board of directors, estimates that the fuel can be sold for 13s. per ton. There is no good reason why the nature of the raw material and the patent process of manufacture should be kept secret.

But a much more serious item in the coal-substitute line is the epoch-making event signalized by the departure on

its first voyage of the ocean-going *Selandia*. This ship is propelled by Diesel oil-engines of 2500 indicated horsepower, which will drive it at 11 knots. Its dimensions are: length 370 ft., beam 53 ft., depth 30 ft., registered tonnage 4964, and cargo capacity 7400 tons. The vessel has been built by Burmeister & Wain, of Copenhagen, the owners are the East Asiatic Petroleum Co., and the route to be served will be between Copenhagen and Bangkok, with variations at each end according to requirements. It is stated that the first voyage, which commenced on February 26, will be prolonged to Japan. The small amount of space required for the oil fuel makes it possible to perform a round trip without refilling, and the fuel will naturally be taken aboard in the East, where it is cheapest. There are no funnels, and the exhaust from the engines is carried up the masts. In addition to the main oil-engines there are others which are used for producing the compressed air required for the starting and reversing apparatus and for generating electric current. Practically all the auxiliary machinery on board is driven by electric motors, namely, the ballast, sanitary, and bilge pumps, the refrigerating plant, the winches, windlasses, and steering gear, and the lubricating-oil pumps. A small boiler is provided, burning oil fuel, for the purpose of heating the ship. A sister ship, the *Jutlandia*, similar in every detail, is being built for the same company by Barclay, Curle & Co. of Glasgow. Burmeister & Wain have another ship of the same type and size nearing completion, and also two larger and two smaller ones. During the last few days it has been reported that the East Asiatic Petroleum Co. has given a further order for two 10,000-ton cargo boats of 3000 i.h.p., and that the Swedish Northstar company has placed orders at Copenhagen for two large steamers. It is hardly necessary to say that the success of the Diesel oil-engine for marine and other purposes will have a far-reaching effect in many industries. They will spread the use of the internal-combustion motor in many directions where continuity of running for lengthy periods is an indispensable feature.

In writing a year ago of the performance of the Nundydroog gold mine, belonging to the Kolar group in India, operated by John Taylor & Sons, I mentioned that the year 1910 was a record one as regards yield and profit. The results for 1911 now published show a still further increase in prosperity. The company was originally formed in 1882, but it was not until 1888 that success was won. Since then the output has steadily advanced, except during the years 1898-1910, when the workings passed through a lean zone. During 1911 the stamps crushed 102,873 short tons of ore, yielding 81,629 oz. bullion by amalgamation, and 8544 oz. by cyaniding, making a total of 90,173 oz., worth £339,243. The amount of ore crushed was greater by 952 tons and the value of the yield greater by £4494 than during 1910. The working cost was £140,002, as compared with £153,812. In addition £21,870 was paid as royalties, and £8252 as income tax; £10,000 has been added to the reserve fund, £10,251 written off for depreciation of plant, £14,475 spent on additional machinery, £3820 paid as percentage of profit to the directors and managers, and £50,000 placed to the 'shares appropriation account.' The dividend absorbed £127,350, being at the rate of 45%, as compared with £117,916, and 41⅔% for 1910. During the year, 12,096 ft. of development work was done, and on December 31 the reserve was estimated at 160,559 tons, an increase of 2308 tons during the year. Additional ground has been acquired during the year to the north and west of the old boundaries. The superintendent, C. H. Richards, gives interesting information as to recent discoveries, all pointing to the continuance of the present satisfactory condition of things. The workings are now down 2450 ft. vertical, or 3050 ft. on the lode. This is one of the most interesting as well as of the most valuable Indian gold mines, and its prosperity is pleasing.

An unexpected slump in Anglo-Continental shares, from £8 to £5, on March 15, caused a collapse in the Nigerian tin department in London. The general tone, however, of the London share market has improved lately.

General Mining News

ALASKA

JUNEAU

The February report of the Alaska Treadwell G. M. Co. shows a production of free gold and concentrate with a 'realizable value' of \$130,051. Operating expenses for the month amounted to \$88,392 and construction expenses to \$15,064, leaving a net profit, estimated, of \$26,595. The yield per ton was \$2.11. The stock of broken ore was increased 4562 tons. During the month 1020 ft. of development work was done. The mill crushed 62,020 tons of ore.

COPPER RIVER

The Bonanza copper mine, the Guggenheim property which disbursed \$10,000,000 in dividends, shipped 16,000 tons of ore, valued at \$3,500,000, in the period for which the dividend was declared, the first nine months of operation, which was commenced last April. The dividend was made possible by the completion of the Copper River & Northwestern railroad.

ARIZONA

PINAL COUNTY

The Ray Con. Copper Co. in February produced 2,140,000 lb. copper, according to its regular monthly report, just issued. The profit for the month was about \$95,000. The January production amounted to 2,476,944 lb. copper. During February the company treated 93,794 tons of ore assaying 1.66 to 1.85% copper. The company has sold all of its March copper, it is reported, a large part of the April, and a fair amount of the May output. More than half of the outstanding Ray Central shares have been deposited for exchange for Ray Consolidated, on a basis of eight for one.

CALIFORNIA

INYO COUNTY

The Skidoo Mines Co. in February produced \$11,602 in bullion. Development and operation costs amounted to \$8724, leaving a net profit for the month of \$3078. The mill treated 1350 tons of ore.

A 10-stamp mill has been ordered for the Wilshire Bishop Creek mine from the Traylor Engineering Co. The mill will have 1250-lb. stamps. Gaylord Wilshire is president of the company owning the property. Algernon Del Mar will have charge of the construction of the mill.

NEVADA COUNTY

(Special Correspondence.)—George Scarfe, manager for the South Yuba Water Co., has notified local mining companies not to depend on water for power purposes after June 10. This is due to the exceedingly light rainfall, which is less than half of normal. The Empire Mines Co. will install an electric-power plant.

Grass Valley, March 25.

Jacob and Joseph Weissbein have brought suit in the Superior Court of Yuba county to recover from the Tarr M. Co. *et al* possession of the old Blue Point property, sometimes known as the Paddy Campbell. The defendants include, in addition to the Tarr company, the New Blue Point M. Co. and E. W. Tarr, former president and general manager for the company. The Weissbein brothers years ago secured possession of the Campbell properties on a mortgage, and it is alleged that they were in possession when Paddy Campbell sold the property in question to the New Blue Point company in 1890. The Weissbein brothers are residents of San Francisco.

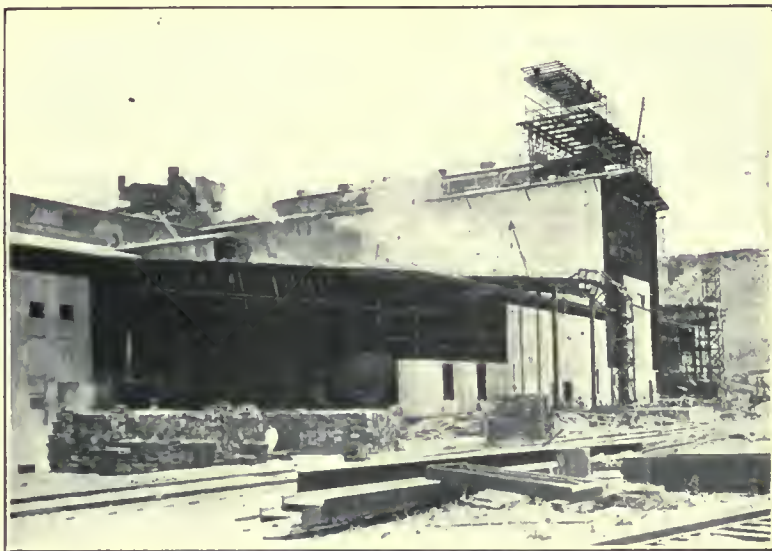

PLACER COUNTY

Henry Jones, M. Langstaff, and associates have acquired

the dredging rights for four miles of river bed along the north fork of the American river, according to advices from Auburn. F. A. Moss and R. H. Young have their shaft at Succor Flat down about 30 ft. They expect to find pay-gravel with a further depth of 60 feet.

SAN BERNARDINO COUNTY

B. J. Bledsoe, judge of the Superior Court, has decided that the F. G. Cottrell device for the electrical precipitation of suspended particles at the California Portland Cement Co.'s plant has met the requirements of his injunction issued a year ago when complaint was made by orange growers in the vicinity that the plant was damaging their orchards. An examination of the groves was

KILNS OF RIVERSIDE PORTLAND CEMENT CO., SHOWING EXPERIMENTAL COTTRELL UNIT AT LEFT AND ERECTION OF PERMANENT EQUIPMENT AT RIGHT.

made recently by R. E. Swain, of the faculty of Stanford University, and it is stated that his report probably was the basis of the court's decision.

SHASTA COUNTY

(Special Correspondence.)—The Blue Ledge copper properties, in the extreme northern part of this county, have passed into the hands of La Compania Metalurgica Mexicana, according to records filed with the County Recorder. The new company is organized under the laws of New Jersey. The purchase price is not given, but is said to be large. The Blue Ledge company has expended a large sum in development work. The property has large orebodies of high-grade copper, containing also gold and silver. Much placer and hydraulic mining is going on in the Salmon river and other districts. The recent rains and snow aided the miners to some extent, but the lack of sufficient water will install an electric-power plant.

Yreka, March 24.

Complaint was made to the Mammoth Copper Co. by a committee of the Shasta County Farmers' Protective Association, on March 26, that fumes from the smelter damage crops as far south as Redding and Anderson, particularly after a rain and north wind. When the Balaklala smelter was shut down about a year ago it was thought that the bag-house at the Mammoth smelter would prevent injury to crops from that source, but the ranchers now assert that sufficient protection is not afforded by the bag-house.

The Afterthought Copper Co. is planning the resumption of work at its property, 20 miles east from Redding. The company owns 19 claims, of which 18 are patented. The present corporation succeeded the Great Western Gold Co., which itself was a reorganization of the Afterthought M. Co. T. H. Adams, of Indianapolis, president of the company, with L. A. Townsend, a director, and S. E. Bretherton, manager for the company, recently inspected the hold-

ings. Mr. Adams said that probable construction of the long-planned branch railroad to connect the property and Bella Vista station would be started during the coming summer. The company is planning to add a zinc-ore treating plant to the smelter.

The Noble Electric Steel Co. has resumed operation of its large furnace at Heroult after a shut-down of a month due to relining the furnace. Several additional furnaces will be put in commission this spring. The Bully Hill Copper M. & S. Co. is planning to resume operation at Delamar by treating zinc ore, and a plant for zinc ore treatment may be built soon. The smelter has been closed for 21 months.

TUOLUMNE COUNTY

(Special Correspondence.)—A boring machine has been installed at the Basin mine to prospect the claims owned by the Columbia Basin & Development Co. The Republican mill is completed and several hundred tons of rich ore now awaiting crushing will be placed at once under the stamps. The adit at the McPherson-McCormick claim, near Jacksonville, will be run to the 1500-ft. mark and active work will be started. At the Melones mine, in the Tuttle-town district, a great find was made last week on the 1350-ft. level on a vein averaging 20 in. The value of the discovery is estimated at \$200,000. The Melones has generally been regarded as a low-grade proposition, though it is situated in a rich pocket district. Work has started in earnest at the Columbus near Tuolumne. Good ore has just been found at the 400-ft. level in the Dreisam mine at Arastraville.

Tuolumne, March 25.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—Warren & Co. have taken a lease on the west Donaldson vein, operation being through the Rockford adit. Shaffer & Co. have taken a lease in the Centurian shaft, work being done between the Rockford and Centurian adits. F. Fransen, manager of the Moon Anchor property, has resumed operation, and shipments will be started soon. The company plans erecting a 25-ton mill during the coming summer. The McKelvey mill is running steadily, with an average of 20 tons of ore per day. A number of improvements are now being made about the plant.

Idaho Springs, March 21.

GILPIN COUNTY

The Ingalls mine, Nevada district, is to be reopened by L. H. Teagarden, according to Central City advices. The property has a 600-ft. shaft. Mr. Teagarden also will reopen the Skelley mine on Quartz hill, near the Illinois and Edinburgh properties. Machinery for both the Ingalls and Skelley mines has been ordered from Denver.

LAKE COUNTY (LEADVILLE)

A new schedule has been offered to zinc shippers, applying particularly to the lower grades of zinc carbonates, with 22% zinc as its basis. It is reported that two zinc-buying companies have bid for the ore. One offers \$3 and the other \$3.50 per ton for the grade mentioned, with 50c. variation per unit.

The machinery for the Mt. Champion M. Co.'s new mill has been delivered at the property, at the head of Half Moon gulch, after considerable difficulty in transportation owing to the recent snowslides. The equipment includes a set of No. 4 Samson crushers, rolls, tube-mill, and two Deister tables. The capacity will be 75 tons per day, but it is reported that if the mill is successful the capacity will be doubled this summer. Work has been continued through the winter and there is a large amount of ore ready. The new mill on the Helena property will be ready in the near future. The collar of the shaft and the head-frame are to be raised 12 ft., and a trestle will be built to the new 50-ton ore-bin at the mill. The Iron-Silver company recently found a new orebody south of the hitherto proved ground. The company in 1911 shipped 46,811 tons

of zinc, lead, and iron sulphides, zinc carbonate, and lead carbonate. The Great Eastern is to have an electric hoist. Shortage of cars has resulted in the storing of 1200 tons of ore in the bins of the Ibex mine.

SAN MIGUEL COUNTY

The Colorado Carnotite Co., of Telluride, owning properties in the Paradox Valley district, is making preliminary plans for the erection of a concentrating plant, according to recent reports. The plant will treat carnotite and other uranium and vanadium ore, of which there is said to be large deposits along the Dolores river, in San Miguel and Montrose counties. Interesting photographs taken by exposure to light from carnotite ore only recently were made at Telluride.

TELLER COUNTY (CRIPPLE CREEK)

William Millar and associates of Victor have obtained a three-year lease on the Jennie Sample G. M. Co. property. L. Campbell and associates, lessees on the Mollie Kathleen property, Tenderfoot hill, recently discovered rich ore in a winze sunk from the 100-ft. level. The Stratton estate is erecting an electric hoist at one of the Longfellow shafts, Bull hill.

T. R. Countryman, engineer of the Roosevelt deep-drainage adit, in a report issued March 18, asserts that the work already has paid for itself. On March 9 a heavy flow was developed in the breast of the adit, and the ground continually caved. The flow increased until from this source 5240 gal. of water per minute poured on March 11. On the same day the flow from the portal amounted to 17,500 gal. per minute. The flow since has decreased 1000 to 1500 gal. The total subsidence in the Gold Coin shaft, measured March 17, was 118 ft., showing a fall of eight feet between March 1 and March 18, or a rate of 15 ft. per month. On a basis of \$5000 per vertical foot as the cost of lowering the general water-level by pumping, Mr. Countryman estimates that the adit has paid for itself, although its benefit has only just commenced to be evident. His report in detail is as follows:

	Feet.
Total distance from shaft to breast, March 11, 1912..	8,876
Total distance from shaft to breast, March 1, 1912...	8,817
Progress March 1 to 11, 1912.....	59
Total progress since resuming work in Sept. 1911...	1,113
Total length of adit, portal to breast.....	16,857

IDAHO

ADA COUNTY

Dredging operations in the Boise basin are producing \$40,000 per month, according to a report in the *Tribune* of Salt Lake City. The area was first worked by American placer miners in the early days, and later re-worked by the Chinese. The Boston & Idaho Dredging Co. has a large Risdon dredge with a capacity of 2500 cu. yd. per day, on Elk creek, and a 15-ft. Bucyrus dredge. The yield is reported to be 17c. to 50c. per cubic yard.

IDAHO COUNTY

A report from Elk City states that at least five companies are preparing to operate this season in the Dixie placer district. The Central Idaho P. & M. Co., for which J. Hudson Wise is manager, cleaned its ditches last fall and is taking in hydraulic pipe and giants. Its property is in Fourth of July gulch. The Idaho Realty & Power Co. has equipment on the ground for an active season. The company enlarged its ditch last fall. S. R. Gayton is manager for the company. The Salmon River Mines Co. will soon start work on the bars owned by the company. Operation will be by the drag-scraper system, and a complete electric plant has been built to supply power. J. R. Painter is general manager of the property, which is about fifteen miles south of Dixie. Construction of flumes and sluices is now going on at the Lemhi bar, owned by the Adams brothers of Chicago. Walter Cook is manager of the property. Several other bars along the Salmon river are being considered by capitalists, it is reported.

MONTANA

LINCOLN COUNTY

(Special Correspondence.)—The Libby Placer Co.'s hydraulic plant on Libby creek, which was built last year, is to be started early in April and will be operated throughout the season, according to John P. Wall, attorney for the company here. It was completed only a short time before winter set in, but was operated during the few weeks that the weather permitted. Then work was suspended until this spring. The company is the largest corporation engaged in placer mining in the Libby district, and owns about 1000 acres of gold-bearing ground on Libby creek. The corporation is composed largely of Butte men, headed by P. J. Brophy.

Libby, March 23.

MADISON COUNTY

The placer mining season will soon open in Alder gulch, if the weather of the past few weeks continues. There is an abundance of water. The Shafter mill at Virginia City is about to be started on ore from the Nelson mine. S. H. Ribbel is manager of the mine for lessees.

NEVADA

CLARK COUNTY

The Searchlight-Spokane mill has been placed in operation and is treating ore from the Princess property. Milton McKee is superintendent of the mill, which is operated by electricity.

HUMBOLDT COUNTY

Charles Ray has found a good vein of gold ore on his claim near Lovelocks.

LINCOLN COUNTY

The Home Run Copper Co. has been incorporated with a capitalization of \$100,000 in 1,000,000 shares. The new company owns eight claims adjoining the Day-Bristol Con. M. Co.'s property in the Jackrabbit district. M. C. Godhe is president of the company, E. S. Woodward vice-president, and H. F. Earle secretary and treasurer.

NYE COUNTY

The Tonopah Extension M. Co. has started sinking a new shaft on its O. K. claim, 1600 ft. west of the present working shaft, and will carry it to a depth of 1000 ft., according to present plans. The present two-compartment shaft is inadequate for the mill, it is said.

The production of the Tonopah district for the week ended March 23 is summarized as follows by the *Tonopah Miner*: "The Tonopah Mining Co. sent 3350 tons, the Belmont company 2250 tons, the Montana-Tonopah 1029 tons, the Tonopah Extension 1085 tons, the West End 638 tons, and shipped 75 tons to the smelter, the MacNamara 440 tons, making the total production for the week 8867 tons, the estimated value being \$221,675."

The Big Four is about to build a mill, according to an announcement by L. K. Koontz, president of the corporation. The first unit is to have ten stamps, and a capacity of 50 tons of ore per day. Friction within the War Eagle M. & M. Co. has culminated in the levying of two attachments, one for about \$25,000 and the other for \$3600, on the mill and other property of the company. The first is on an alleged promissory note, held by W. C. Lamb, and the second is on claims of the Wittenberg Warehouse & Transfer Company.

STOREY COUNTY (COMSTOCK LOBE)

The report of C. H. Fish, superintendent for the Con. Virginia M. Co. for the year ended February 29, shows that during that period 3077 tons of ore was produced. The previous report stated that 552 tons was in process of reduction, and with this the total amount of ore treated during the year in the Sutro mill was 3629 tons. There is on hand in the bins 12 tons of ore assaying about \$94 per ton, and 189 tons assaying about \$24 per ton. On March 1 the designation of levels in the mine was changed to conform to the system used in the Mexican, Ophir, Union Con., and Sierra Nevada mines.

Operation is to be resumed soon on the Clermont Con.

G. & S. Co. property, in the Flowery district, east of the Comstock. L. J. Murphy was elected president of the company at the annual meeting recently held. J. D. Moore is superintendent of the property. The main shaft is down 110 feet.

For the week ended March 23, work in the Ophir was confined principally to the 2100-ft. level. The total production for the week was 192 tons averaging \$27.80. Along with the usual repair work, the Con. Virginia mine produced 43 tons of ore averaging \$23.97. The usual repair work was done in the Union. The Mexican mill ran 67% of the time and treated 404 tons of ore, of which the gross assay value was \$9817. The Crown Point produced 252 cars of ore, averaging \$6.17 per ton. The Comstock Pumping Association report for the week shows that the water on Saturday stood about 295 ft. below the 2300-ft. level.

WASHOE COUNTY

Press reports state that James Seeoy, owner of the Nar-

PART OF NEVADA AND CALIFORNIA.

ragansett group of claims, has discovered the source of rich float found on that property, which is a few miles to the north of Reno. The discovery was made in a shaft now being sunk by Seeoy, at a depth of 56 ft. One assay of the ore is reported to have shown 300 oz. silver and 1 oz. gold per ton.

WHITE PINE COUNTY

The Giroux Con. Mines Co. is now hoisting ore from the Bunker Hill shaft, and in a few weeks should begin steady shipment to the Steptoe concentrator at McGill. Retimbering is being done in the lower workings of the Bunker Hill. Pumping for one hour per day is sufficient to remove the water in the sump. At the Morris the four boilers have been bricked in, and pipe connections are being made. The two large hoists for the skips are in place, but have not been connected. A smaller hoist will operate the cage in the third compartment of the shaft. Much heavy work remains to be done in building the ore-bins.

The Veteran is shipping about 1100 tons of ore per day. The ore is taken from the 400-ft. level, where the caving system is being used. The company has about 325 on the payroll.

NEW MEXICO

GRANT COUNTY

George Uter is reported to be planning additions to his zinc concentrating plant near Silver City. He recently shipped a carload of concentrate to Oklahoma. The Chloride Flat M. Co. is making regular shipments of silver ore to the El Paso smelter.

UTAH

BEAVER COUNTY

Work has been resumed at the Moscow property. Development is being concentrated on the new ground recently acquired. The Summit M. Co., of Frisco, has been organized to develop five claims adjoining the Blackbird M. Co.'s property. J. L. Griffiths is president of the new company.

JUAB COUNTY (TINTIC DISTRICT)

The Tintie M. & D. Co. is about to sink a new shaft on its property at Mammoth. It is intended to sink the shaft about 500 ft. before driving is started. The new shaft is to be situated in the cross-cut from the main adit, about 2700 ft. from the portal. James Fitzgerald is in charge of the work.

The Eagle & Blue Bell shaft has almost reached the 1300-ft. level, and by the close of next month William Owens, superintendent of the property, believes the 1400-ft. level will be reached. About a carload of ore per day is being shipped while shaft-sinking is in progress.

SALT LAKE COUNTY

The Utah-Apex earned during the six months ended February 29 a net profit of \$100,006.

An adit for drainage, development, and transportation is to be driven on the Maxfield property, Big Cottonwood district. The water from drainage is to be used to generate power. It is reported that the Colonia, Maxfield, and Big Cottonwood Con. properties are under option to the people planning the new adit.

The Bingham-New Haven Copper & Gold M. Co. has paid its customary dividend of 10c. per share. The company is shipping about 200 tons of ore per day to the A. S. & R. Co.'s plant at Garfield. The ore assays 3 to 5% copper and about \$5 per ton gold, according to a Salt Lake report. Stock issued amounts to 228,629 shares.

TOOELE COUNTY

The second lead furnace of the International S. & R. Co. has been blown in, according to a recent report from Salt Lake City. About 800 tons of ore per day is being treated in the company's three copper reverberatories.

WASHINGTON

OKANOGAN COUNTY

Operation has been resumed at the Duluth-Toreda mill at Chesaw, after a shut-down of several months. The Poland China, in the same district, will resume in a short time. F. J. Barnham, of Holyoke, Massachusetts, representing the note-holders of the corporation, acquired the assets of the Palmer Mountain Tunnel Co. at Loomis, at a receiver's sale in Spokane, for \$25,500, and will continue the development work, according to recent reports.

SPOKANE COUNTY

Frank R. Culbertson, chairman of the mining committee of the Spokane Chamber of Commerce, has announced that the public land question will be the keynote of the annual meeting of the American Mining Congress in Spokane in November. Governors of Washington, Oregon, California, Nevada, Arizona, New Mexico, Texas, Oklahoma, Utah, Colorado, Wyoming, Montana, the Dakotas, Minnesota, and other states will be invited to participate in the discussions. J. F. Callbreath, secretary of the Mining Congress, will open offices in Spokane next summer.

J. F. Callbreath, secretary of the American Mining Congress, says in a telegram from Washington to the Spokane Chamber of Commerce:

"Your invitation to hold in Spokane the fifteenth session of the American Mining Congress has been accepted by the almost unanimous vote of the directors of the congress. The congress will meet in Spokane during the week of November 18, unless you prefer some other date."

The Northwest Bureau of Mines, recently organized in Spokane with William A. Nichols as president, and the Spokane Mining Men's Club, headed by L. K. Armstrong, will cooperate with the Chamber of Commerce.

CANADA

BRITISH COLUMBIA

The Hedley G. M. Co. has declared a quarterly dividend of 3% and an extra dividend of 2%, payable March 30 to stockholders of record March 20. The company is about to commence treatment of the contents of its slime pond, in which lies the accumulation of about six years.

It is reported that \$12,000,000 will be expended by the Northern Anthracite Syndicate, recently organized by Andrew Laidlaw, of Spokane, Washington, in developing 12,800 acres of coal lands in the Groundhog Mountain district, 150 miles north of Hazelton. The work, which will occupy three years, will include building a railroad from the forks of the Skeena and Stikine rivers to the mouth of the Nass river and Nasoga gulf, and bunkers on the Pacific coast. Surveys will be made this spring.

ONTARIO

(Special Correspondence.)—In the Poreupine district properties in the prospect stage are proceeding with development, while the unproved properties are marking time or waiting idly until success or failure of the large properties is definitely decided. The Rea, under the management of O. H. Bergstrom, is being developed as rapidly as possible, the main shaft having been continued to the 400-ft. level. Cross-cutting has been started to reach the orebody at that depth. At the Hollinger the usual development is being carried on. Mill construction is being rushed. The McEnaney management is sinking the shaft on the No. 2 vein to the 300-ft. level to prospect the orebody at that depth. The No. 2 vein has shown free gold in numerous places. Four diamond-drill holes have been put in from the 100-ft. level, cutting the vein at 150 and 180 ft., proving an orebody 2½ to 4 ft. wide. The cores show ore assaying \$10 to \$300 per ton, the average assay being \$20.

The Poreupine Gold, Vipond, management, is pushing development and has the excavating for the mill foundation almost completed. The stamps at the Dome will begin dropping on March 22 and the new mill is doing excellent work. The opening of the mill will be celebrated by a large banquet, for which many invitations were sent out, and a large attendance is expected.

Poreupine, March 23.

YUKON

Prospectors in the Sixtymile district are preparing to leave, according to T. D. Macfarlane, Government inspector, who has returned to Dawson from a trip to the district. He stated that considerable prospecting had been done on Weide, Christmas, Fortier, Borden, Angus, Marion, Emma, Nettie, and Pine creeks, as well as along Sixtymile. In the last district he stated that, excepting Matson's discovery-hole and No. 1 Below, the total gold recovery would not exceed 15 cents, although 65 shafts had been sunk to bedrock, which was of soft schist.

The Yukon Gold Co. in 1911, by its dredge and hydraulic operations, produced \$3,116,227, as against \$2,847,108 in 1910, an increase of \$269,119. The gross hydraulic production amounted to \$444,382, as against \$696,375 in the preceding year. The decrease is attributed to the fact that the mechanical elevators were not operated, as the dredges did the work much more economically. The production by dredging totaled \$2,671,845 gross gold, an increase of \$521,112 over the production in 1910. Two dredges were added during the year, making an equipment of nine in all. The total yardage was increased by 1,930,000 cu. yd., as the company acquired a number of claims by purchase and working agreements. Dredge operation was started three weeks earlier than in the preceding year, and during the season 4,159,249 cu. yd. of gravel, averaging 64.35c., was handled. In 1910 only 3,249,788 cu. yd. was handled, but this averaged 66.18c. per cubic yard. Costs increased from 31.09c. to 35.43c., the net yield being 28.92c., as compared with 35.09c. in 1910. Hydraulic operation handled 2,125,551 cu. yd. of earth, a 19% increase for the season. Despite unusually low water during the latter part of the season, a cost record of 15.5c. was made for the

year, the lowest in the company's history. The company reports an increase of \$4233 in the surplus, bringing it to \$386,654. For depreciation \$434,108 was written off, an increase over the preceding year of \$145,309.

MEXICO

While the revolution has interfered with much foreign commercial activity and with many mining ventures, according to late press advices, not all the properties are affected by the internal political troubles of the country. The A. S. & R. Co. smelter at Aguascalientes is in operation, although interruptions in the train service have stopped ore shipments from the north. If the San Luis division of the National Railways is put out of commission, however, the smelter will be able to run only a week or so. The La Dura M. & M. Co. property, in Sonora, is still in operation, and the usual production is being maintained, according to late reports. According to good authority, the Compagnie du Boleo, in Baja California, is operating as usual. The West Mexican Mines, Ltd., of Guadalupe y Calvo, mill has been shut down, but those in charge are not alarmed at the outlook. Most of the Parral district properties are being operated.

WESTERN AUSTRALIA

(Special Correspondence.)—On February 10 a cyclone did a great deal of damage in this town and around the mines. The Power company's mains are down, and the Boulder, Kalgurli, South Kalgurli, Perseverance, Lake View & Star, and Oroya Links mines are temporarily almost at a standstill. January was excessively warm. The temperature rose to over 109° on the 29th, and on eight days in the month 100° or over was registered. On February 1 the mercury rose to over 111 degrees.

Kalgoorlie, February 10.

Among the Copper Mines

The Elmore vacuum plant at the SULITJELMA company's mines, Norway, during February produced 876 tons of copper concentrate.

UTAH CON. in February produced 16,000 tons of ore, which exceeds the 1911 average monthly production by 2000 tons, according to a report from Salt Lake City.

The MIAMI COPPER CO. produced 983,500 lb. copper in the ten days ended March 20, as against 594,140 lb. in the first ten days of the month. It is believed that when the machinery gets into good working order the concentrator can turn out more than 3,000,000 lb. of copper per month. The sixth unit was put in operation at the end of February.

THEODORE PHILLIPS has discovered a large deposit of ore resembling in appearance that of the Ray property on land situated at Christmas, Gila county, Arizona, according to recent press despatches. The A. S. & R. Co. is reported to have secured options on every promising claim between Hayden and Troy. The options cover all claims around Christmas excepting the Christmas mine and the claims held by Phillips.

The A. S. & R. Co., according to a New York report in the *Boston News Bureau*, in the year ended December 31, earned, before deductions, more than \$6,000,000. This includes the Smelters' equity in the earnings of the American Smelters Securities on its common stock, now all owned by the A. S. & R. Co. The Smelters' earnings on its common stock, after deductions, will show about \$4,500,000, including the equity in the Smelters Securities common stock.

The RAY CON. COPPER CO.'s annual report shows the following assets on December 31: Property, \$7,903,383; expenditures, additions, construction, equipment, and development, \$6,716,119; deferred charges to future income,

\$22,742; cash in banks, \$59,813; equity in copper in transit, \$778,256; supplies, \$450,950; accounts receivable, \$81,643; treasury stock, \$500; outside investments, \$1,025,000; total, \$17,038,409. Liabilities: capital stock, \$11,991,750; first-mortgage bonds, \$3,000,000; accounts payable, \$950,000; freight and treatment, \$294,918; deferred liabilities, \$75,200; surplus from sale of securities, \$259,137; undivided profits, \$298,640; total, \$17,038,409.

ALTOGETHER 44,736,617 lb. of copper, valued at \$10,275,767, was exported from Japan to various foreign countries during 1911, the figures showing a decrease of 1,612,802 lb. and \$412,329, as against 46,349,266 lb. and \$10,558,097 for the previous year. The decrease is attributed to the accumulation of stocks in the European and American markets, consequent upon the economic inactivity abroad. Of the total export, copper ingots and bullion were exported to the extent of 44,079,564 lb., valued at \$10,006,290; copper sheets to the extent of 352,864 lb., valued at \$96,628, and copper wire to the extent of 304,188 lb., valued at \$78,849.—*Japan Times*.

Goldfield Consolidated Report

The total production of the Goldfield Consolidated Mines Co. during February 1912 was 27,641 tons of ore, containing \$740,793, or an average of \$26.80 per ton. The whole was milled with an average extraction of \$25.08 per ton, or 93.57%. The total net realization was \$487,262, or \$17.64 per ton. During the month, 2869 ft. of development work was performed. The total cost of mining, development, milling, office and general expense was \$7.47 per ton, distributed as follows:

Mining:	
Development	\$0.96
Stoping	2.62
	<hr/>
Transportation	\$3.58
Milling	0.09
Marketing	2.19
General expenses	0.33
Bullion Tax	0.48
Construction	0.26
	<hr/>
Total cost of operation	0.54
Miscellaneous earnings	
	<hr/>
Net cost per ton	\$7.47
	<hr/>
	0.03
	<hr/>
Net cost per ton	\$7.44

The sill of the 428 stope in the Clermont, being cut from the 466-intermediate between the 650 and 750-ft. levels, was considerably extended, and produced 561 tons of ore averaging \$48.57. The 604-raise from the 1000-ft. level rising up toward the 534 on the south end of the 900-ft. level produced 472 tons of ore averaging \$93. The 3-E sill on the 150-ft. level in the Mohawk near the old Sheets-Ish workings, was again extended and produced 59 tons of ore averaging \$17.57. The 3-D sill on the same level is being extended along the south end of the old Sheets-Ish workings, and produced 70 tons of ore averaging \$70.27. The No. 29 drift, being cut around the 3-E stope in the foot-wall, has found the extension of the 3-E ore, and produced 30 tons of ore averaging \$15.30. The 111-M sill was considerably extended, and produced 854 tons of ore averaging \$14.67. The 415-X cross-cut from the 491-intermediate, between the 450 and 600-ft. levels, produced 198 tons of ore averaging \$41.13. The 491-sill, being cut from the 415-X, has produced 111 tons of ore averaging \$23.35. The 353-intermediate of the Red Top, between the second and third levels, just north of the shaft, has been extended, and produced 90 tons of ore averaging \$41.34. Work through the Red Top shaft has been discontinued, the Laguna surface plant and shaft now serving both mines. The 292-O sill, being cut from the 295-X cross-cut on the fourth level, south and west of the Hampton stope, in the Combination, produced 138 tons of ore averaging \$20.87.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

C. W. MERRILL is at Poreupine.
L. A. GREENE has gone to Chicago.
HOWARD D. SMITH is in New York.
O. McCRAVEY is at Tonopah, Nevada.
FRED L. LOWELL has gone to Amador City.
JEROME B. LANDFIELD is in San Francisco.
H. W. HARDINGE is examining mines in Arizona.
GELASIO CAETANI has gone to Telluride, Colorado.
FRED SIEBERT was in San Francisco during the week.
MALCOLM MACLAREN has left San Francisco for London.
CHARLES JANIN sails today from New York for London.
T. A. RICKARD will leave for Denver on Tuesday morning.

A. K. SCHELLINGER has gone to Dawson, Yukon Territory.

GEORGE H. GARREY has returned to New York from Mexico.

JOHN B. FARISH was in San Francisco and has gone to Denver.

C. T. HUTCHINSON and T. A. RICKARD visited Coalinga this week.

K. P. SWENSEN has accepted a position with F. W. HORNE at Yokohama.

S. P. MACKNIGHT has moved from Kingman, Arizona, to Randsburg, California.

GEORGE T. COFFEY and C. A. THOMAS are leaving for Dawson, Yukon Territory.

FRANCIS DRAKE has gone to Rhodesia as consulting engineer for Lewis & Marks.

F. M. SIMPSON has returned to Berkeley from San Jose de Gracia, Sinaloa, Mexico.

ENRIQUE VALLE is in charge at the Santa Catarina mines at Taviche, Oaxaca, Mexico.

PAUL MESSER and Mrs. MESSER are expected in San Francisco from Yokohama in May.

G. A. SWANQUIST has left Salvador, Central America, and is now at Cripple Creek, Colorado.

A. C. FRENCH is in charge of the development for the Lost Josephine Mining Co., near Provo, Utah.

A. M. HARRIS has succeeded A. B. STROCK as superintendent for the Marysville Gold Dredge Co., at Marigold, California.

C. H. HOLLOWELL has resigned as superintendent of the Millerette mill at Gowganda, Ontario, to take charge of the Powerful mine, at the same place.

HENRY B. KAEDING is on his way to New York from Bluefields, Nicaragua, and should be addressed in care of the American Institute of Mining Engineers.

NORMAN C. STINES returned to Nikolaievsk late in February from a 600-mile journey down the Amur, and expects to leave just before the breaking up of ice travel.

J. M. CALLOW, consulting mill engineer for the Inspiration Copper Co., has returned to Salt Lake City after four months absence on professional work in connection with the new mill.

N. P. TURNER has resigned his position as chief engineer of the Cuba railroad. In association with L. D. MOORE, of New York, he will take up mining and general engineering and exploration in the West Indies, Central and South America, with headquarters for the present at Hotel Camaguey, Camaguey, Cuba.

'SMELTOR' has sent us an interesting letter which we will be glad to publish if he will furnish us with his name and address. Anonymous contributions will not be published under any circumstances.

EDITORIAL

COPPER continues to advance in price in spite of industrial and political disturbances, both at home and abroad, and many of the larger companies are increasing their dividend rate.

LETTERS to the editor are always a source of interest, but are sometimes cause for astonishment. One such, recently received, contains a request for "the names of the mineral mines in operation in the United States, Mexico, and South America; also the addresses of their superintendents."

ATTEMPTS to minimize the effects of the gases and fume emitted by smelting plants are of great importance on the Pacific coast, and we are glad to present this week an account of the results so far obtained with the Thiogen process at the smelter of the Penn Mining Company at Campo Seco.

THE second annual meeting of the Pacific Association of Scientific Societies was held at Stanford University this week, and members of twelve learned societies have been in attendance. The Cordilleran section of the Geological Society of America held its meeting on Friday and a notable list of papers was presented.

VEINS and their structure offers many puzzling geological problems, and some unusual features of the remarkable cretulated veins of the Nova Scotia gold deposits, are interestingly discussed by Mr. T. A. Rickard, in a contribution to the Canadian Mining Institute, of which a portion appears in this issue.

A MEDAL of honor was presented Mr. Robert E. Peary by the Peary Arctic Club on Friday, in commemoration of the third anniversary of the reaching of the north pole. It is interesting that though the north pole baffled the attempts of explorers for a long period the south pole was attained after but a brief period of effort.

PREPARATIONS are well under way for the eighth International Congress of Applied Chemistry, which is to be held in Washington, D. C., during September next, and the titles of a hundred papers to be presented have been announced. No effort is being spared to make this a notable event in the world of chemical engineering.

COAL in British Columbia is a source of interest just now. Spokane investors are reported to be about to expend \$12,000,000 in the Groundhog Mountain district, while Montreal and Toronto capitalists are similarly interested in coal lands on Vancouver island. The Pacific coast, which until the advent of fuel oil was but inadequately supplied with fuel, now seems likely to have an abundance.

APPPOINTMENT of Mr. Talcott Williams, associate editor of the Philadelphia Press, to the head of the newly constituted school of journalism at Columbia University meets with general approval. An untilled field lies before his plow, and an opportunity to exert a widespread

influence that will surely not be allowed to escape. When daily journalism shall have been made worthy of respect we shall hope to see technical journalism rendered worthy of honor.

VENTILATION problems are not peculiar to mines, and the modern development of subways has brought them to the fore in acute form. Both in New York and London it has been found difficult to secure a proper circulation of fresh air, and the necessities of construction to facilitate speed of operation often militate against proper circulation of air currents, which are also disturbed by the erratic movements of the trains through the 'tube.' Attempts have been made to supplement ordinary ventilation by fans, and 80,000,000 cubic feet of air is driven daily into the London underground system. But with 'workings' of so great extent and with so numerous connections with the surface it is hard to control the air currents, while the 'dead' odor which is noticeable but not objectionable in mines is a cause of much protest on the part of the underground traveler.

BEWILDERMENT is the usual outcome when the average man attempts to grasp the intricacies of foreign exchange, and the American drawing on a letter of credit abroad often has little first-hand knowledge as to whether he has been justly dealt with or not. When a concrete problem is so puzzling, it is not remarkable that an apparently interminable discussion wages over the question as to whether the increase in the production of gold is the direct cause of increase of commodity prices or not. The argument that commodities are cheaper in New York than along the Yukon is not so convincing upon close examination as on first view. The stock of gold in the world is so small in comparison with the amount of business done, and the latter varies so greatly and independently of changes in the former, that it is evident that correlation between them is not a simple one. Mr. Irving Fisher has worked out a mathematical formula showing that prices depend on the volume of trade, the amount of currency in circulation, its circulating velocity, and the amount of bank deposits and their activity; but this is only true in general, and disquieting variations occur. Where the shoe pinches is in faulty adjustment to conditions, as conditions change in the evolution of industry.

LOOSENESS of specifications is often responsible for much dissatisfaction in construction work. In a letter to the editor of *The Cement Age*, Mr. Leslie H. Allen cites the case of a firm which furnished an estimate upon a \$200,000 reinforced concrete building in competition with five other firms, after having devoted the entire time of one man for two weeks, and a second one for one week, to making estimates, and having secured bids from eighty subcontractors. The cost of this must fall upon the ultimate consumer, the firm which lets the contract, and in the final analysis it must pay five firms to do work a large part of which should have been done by the one asking bids. When the specifications are loose the bidder must either employ the time of his own staff to fill the gaps or must make ample allowance for contingencies, with the result that the bid is larger than it otherwise would have been. The members of the English Master Builders Association refuse to bid on work costing over £1000, unless quantities are supplied to bid upon. Even this is not entirely satisfactory, for the methods and results of estimating quantities vary greatly, according to the personal equation of the engineer. Nevertheless, this is an enormous advance over the practice of some mining companies in calling for bids; the story is told of the successful business man, who,

in his newly assumed rôle of manager of a mining enterprise, told his friend and club-mate, "Joe, I want you to build me a good mill." Needless to say, the ensuing transactions were satisfactory to neither side. The prevention of unnecessary waste is now the order of the day, and may well exhibit itself in the prevention of unnecessary and useless effort.

MUCH interest has been aroused by the reports which have appeared in the daily press concerning High Grade, as the Hogue mining district in Modoc county, California, has been rechristened. The mining centre is about eight miles from New Pine Creek, a station on the Northern California & Oregon railroad, but some of the prospects are in Lake county, Oregon, as the district adjoins both that state and Nevada. There is good reason to believe that the excitement is the artificial product of speculators and promoters who wish to dispose of their holdings, as, on the authority of an engineer who is thoroughly familiar with the district, we are informed that there are only three properties which so far merit attention: the Sunshine, Consolidated, and Big Four. Small and erratic rich streaks of ore occur in brecciated andesite, and the low-grade ores are not developed sufficiently to allow any accurate judgment of their possibilities. As the district lies at an elevation of 8000 feet and snow covers the ground from November to June, the early prospector is likely to reap only disappointment.

Primitive Metallurgical Methods

Primitive methods are always interesting, since they give direct evidence of the development of art and industry, and are no less useful, since they often afford hints as to possible makeshifts when the regular conduct of work on a more elaborate scale is interrupted by unfavorable conditions. For this reason the discussion of the early history of cupellation, presented in this issue, will interest many of our readers. The importance of early vague references to a topic is apt to be exaggerated, however, since the translator reads the words of the ancients in the light of present knowledge; so that, like the poetry of Browning, the content of the text is measured by the concepts of the reader. This is especially true of the references to mining topics in the poetical Book of Job, which, as Dr. R. W. Raymond pointed out in the *Mining and Scientific Press* of April 7, 1906, though ostensibly describing a state of knowledge pertaining to a much earlier period, cannot with authority be taken as portraying a period any earlier than 750 B. C. The generally accepted belief that cupellation was first practised at the mines of Greece and the Mediterranean provinces is probably not an incorrect one, at least so far as Mediterranean civilization is concerned. That in early times silver was much more difficult to obtain than gold, as it occurs less commonly in the metallic form, is shown in its less general employment for objects of use and adornment. King Menes, who is supposed to have ruled Egypt in the 38th century B. C., fixed the ratio of exchange at two and one-half of gold to one of silver, and silver remained more valuable than gold until 2000 B. C. Early in the development of Indian and Chinese civilizations silver was adopted as the medium of exchange, and the extensive silver-lead mines of the Shan states are known to have been worked in very early times. How early will doubtless never be known, as the writing materials of the Chinese are not well adapted to the preservation of ancient records, and the use of inscriptions upon stone as a method of preserving records seems never to have occurred to these ingenious people until after the destruction of the books of the period by Imperial command in 210 B.C. It would not be re-

markable, however, if the invention of cupellation were due to early workers of the deposits of the Shan states, since cupellation is there necessary to obtain the silver. The Far East is still the place in which to observe the operation of primitive methods, and numerous writers in recent years have described the methods employed by the natives of western China for the manufacture of cast and wrought iron, and in southwestern China in producing copper, tin, zinc, quicksilver, and antimony from their ores. Primitive methods may be seen in the Philippines, but are doubtless ascribable to early Spanish influence, while the intensely interesting methods formerly followed in Japan, especially for the production of copper, were perhaps not entirely free from Dutch influence. The early metallurgist was not a prominent member of society and failed to get his name into the 'Who's Who' of the day, so that historical research on metallurgical topics is commonly hampered by lack of records and results are indefinite and inconclusive.

Mexico and Intervention

Conditions in Mexico continue to be so disturbed as to make impossible any accurate forecast of the outcome. The 'Liberal' army, under leadership of Pascual Orozco, dominates the situation in Chihuahua and has gained recent advantages over the federal troops sent against them by the Madero government. In the south Emiliano Zapata has not only maintained himself but has extended his authority over several states. Recently one of his officers demanded the surrender of Puebla. Both Zapata and Orozco are supposed to be acting in behalf of Vasquez Gomez, who, from a secure position at San Antonio, Texas, issues, from time to time, addresses and pronouncements. It is by no means certain that there is a real bond between the leaders of the various factions of discontent, and it is widely believed that success of this re-revolution would but lead to disagreements and further revolts. In the meantime, over much of Mexico local authorities are left to their own devices. The results are good when strong able men are in office, and bad where weak or cowardly men have happened to be in power; which indicates that human nature in Mexico is much like it is in other parts of the world. A recent traveler through Jalisco states that conditions there border on anarchy in that there is no recognized authority. It is not surprising that robbery and open brigandage are rife. It is rather notable instead that there have been few murders and that in many parts of the country, and especially in the cities, life goes on much as usual. Most of the larger mines and many of the other industries continue operations, though train service is irregular on many lines and labor shortage is felt at many points. Work on the Conchos river dam at Boquilla has gone forward steadily with plenty of labor and has only been hindered by irregular receipt of supplies. The Aguas Calientes smelter is running, though some regular sources of ore-supply have been closed. Friends in Sonora state that aside from occasional visits from "horseback hoboos" they have suffered no interference.

The outlook for settled conditions is undeniably gloomy, and the interference with business, native and foreign, is serious. Persistent efforts are being made to embroil the United States with Mexico, and intervention has been called for by many. No self-respecting government can or will permit its citizens in foreign countries to be subjected to needless indignity, loss, or danger, and with the large number of Americans in Mexico and our extensive interests in that country, there is inevitably much danger of rupture of friendly relations if conditions long remain so disturbed. The people and the governments of the two countries have been conspicuously friendly through many years. In the

time of Maximilian the good offices of the United States were freely exerted in behalf of the Mexican people and the pressure exerted on Napoleon III by the Washington Government was an important factor in the re-establishment of the Mexican Republic. Speaking generally, there is but one wish north of the international boundary line, and that is to see a strong, stable, republican government in Mexico. Intervention in any form would be as unpopular in the United States as in Mexico. There is no danger of it occurring except through a rush of popular feeling following some great disaster, accidental or designed. It is widely believed in the United States that the *Maine* was blown up to inflame public opinion and force intervention in Cuba, and it has recently been made a matter of court record that a faction in the United States does not hesitate to dynamite buildings and kill innocent people in the conduct of a labor war. There is in many parts of Mexico a slumbering hatred of Americans, a feeling not unnatural when all circumstances are taken into account, and this is an element of danger. It is also true that, along with the many high-minded and honorable Americans in Mexico, there are those of whom the country is not proud, and here is a second element of danger. Unpopular as is all thought of intervention, a riot, such as has frequently occurred in many of our own states, coming at this time, might easily inflame popular opinion to a point beyond control, since no one supposes the United States would tamely submit to any number of its citizens being killed or jeopardized. Americans in Mexico are in the same position as Italians in the United States. They are entitled to the full measure of protection that the local government can give. Neither is entitled to more, and until the *de facto* government of Mexico fails to protect foreigners as well as it protects its own citizens, no foreign government has just cause for complaint. Hardships, loss, and danger come to all, native and foreigners, who reside in a country in time of civil war. It was true in the United States in 1861 to 1865, and is true now in Mexico. We regret it keenly. Many of our personal friends are, in this instance threatened, but Mexico belongs to the Mexicans and they are entitled to settle their affairs in their own way. If the world was patient with us for four years during which our civil war caused the greatest distress in England and much loss in France, we hardly can complain of the Mexicans in the present instance.

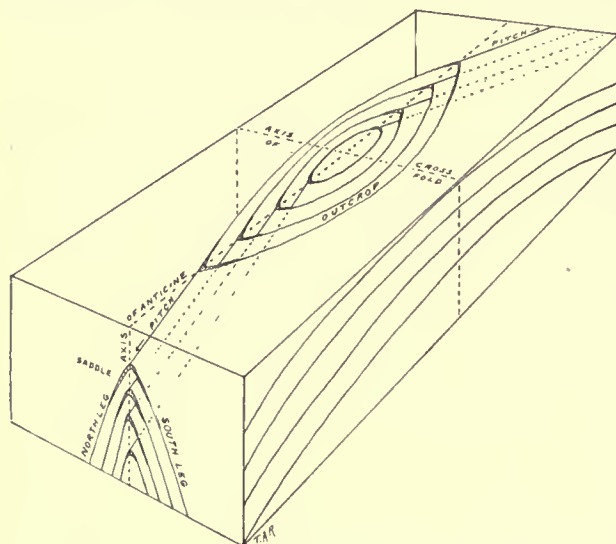

Francisco I. Madero is president of Mexico by the same sort of title as was held for so many years by Porfirio Diaz. If the Mexican people desire to make a change that is their right, and it is not our duty even to see that they abide by rules they have themselves laid down. The great majority of the Mexican people wish for peace and stable government as ardently as we can wish it for them. It is one of the unfortunate results of the, in many particulars, excellent regimen established by Diaz that the people as a whole have not come to think of themselves as responsible units in government. They wish for good government—but to fight for it is different. We may misjudge the forces now in the field for the so-called Liberal party, but in our opinion they are fighting mainly for spoils. The cry for division of estates carries but little conviction so long as the movement is backed and financed mainly by large land-owners. Leaders of the old *Cientifico* party are entirely too prominent in the movement to engender much belief in sincere reform. The Madero government has by no means lost the fight and at any time may re-establish its authority in the disaffected states. In the meantime both federal and revolutionary forces have been conspicuously regardful of the rights of aliens, and we trust no American will do anything to precipitate trouble between the United States and Mexico. Only a premeditated crime or a criminal blunder can excuse intervention.

The Domes of Nova Scotia

By T. A. RICKARD

*The gold is associated with quartz, which in the main follows the bedding of the country rock; hence it forms sheeted bodies of ore that are sandwiched between the strata, especially along the thin seams of slate. Since the quartz follows the structural lines of the country rock, it forms 'saddles' where the slate and quartzite have been bent into antilinal folds; but the most pronounced development of ore—for sometimes the quartz contains enough gold to constitute ore—is on the 'domes' formed where folds cross each other.

This domical structure leads to interesting results. Owing to erosion, the crests of the domes have been degraded to the level of the present surface, on the plane of which the bedding now assumes elliptical form. Any vein of quartz deposited along a bedding-plane will reproduce this structure. If on a flank of the dome, north or south, it will have a nearly straight strike, but in the approach to the ends, east and west, of the dome, it will curve in accord with the fundamental structure. At the 'nose,' or extreme ends of the longer axis of a dome, the quartz will be curved to a

IDEAL DIAGRAM.

bow. All this is on the plane of the surface. If followed underground such a quartz vein will form a saddle, by being curved with the bedding of the antilinal fold whose axis is east and west. Again, owing to the synclinal fold, whose axis runs north and south, the saddle will pitch or slope if exposed at the east or west end of the dome, where the strata plunge in accord with the synclinal curvature of the cross-fold. This description will be made clearer by reference to the accompanying diagram, which, in effect, exhibits the appearance of a model made of glass. The top of the block represents the geological surface; the elliptical outcrops are evident; at the west end of the curving strata are shown the quartz veins. These in cross-section, as exposed at the left side of the block, constitute 'saddles,' the pitch of which is indicated.

Only a small portion of the total gold contributed by Nova Scotia has been extracted from quartz at the apex of these domes. Most of it has been broken from interbedded veins associated with the legs or stumps of arched structures whose crests have vanished. It will be understood that the present surface, from which all mining starts, represents a nearly horizontal section that has been cut, by erosion, through the folds at a varying distance from their crests. The bedding-planes, and the quartz veins conforming to them, that are least curved, are simply farthest from the

antilinal crests, since all the beds of slate and quartzite are members of the folded series. The greater the distance from the antilinal axis the less the curvature, so that many veins following the nearly straight strike and nearly vertical dip of the country appear to be unrelated to quartz deposits on the domes, although structurally they are allied. Such veins follow the lower portion of an arch, the crest of which, at a higher horizon, since denuded, overlapped the dome that survives in the centre of the fold. A distinction must be

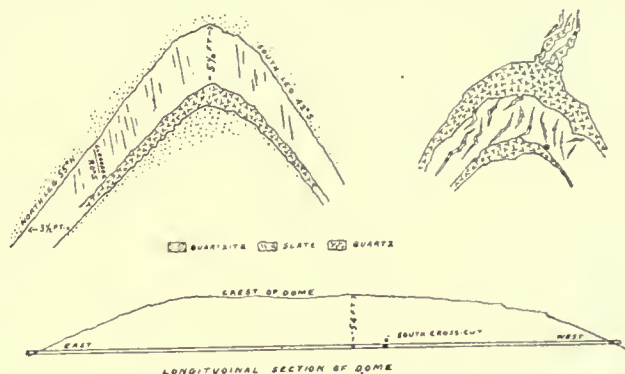

FIG. 2. SADDLES AND DOME STRUCTURE IN DUFFERIN MINE. SKETCHES OF VEIN NO. 1A, ON THE 300-FT. LEVEL.

made, however; it is not necessary to assume, as some writers have done, that every quartz vein at one time extended over an arch of rock that has since been removed. That is another question. Whether the quartz was contemporaneous with the entire fold of the country rock before it was reduced by erosion to the level of the present surface is a point on which I shall speak later. At present I am dealing with facts only, not theory. It is advisable to follow the scientific method of proceeding from the known to the unknown. It is not necessary to assume, and I do not believe, that the quartz vein distant from a dome, or an antilinal arch, is a

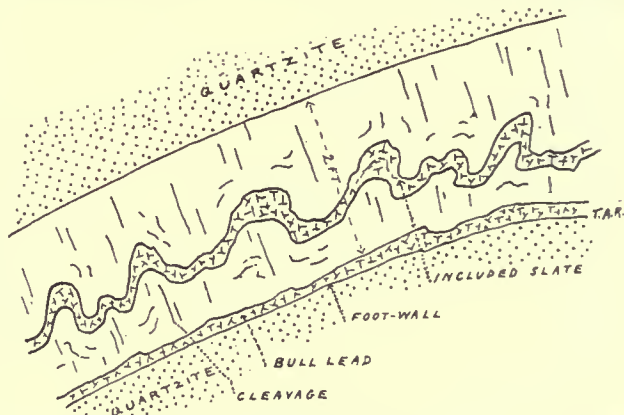

FIG. 3. CRENULATED QUARTZ VEIN IN MIDDLE OF SLATE BAND AND CROSSING CLEAVAGE.

part of a much more extensive body that covered the crest of a dome eroded long ago, nor that the interbedded quartz now found several thousand feet from any antilinal axis was contemporaneous in its origin with, however dependent in structure upon, the lines of weakness created in the rock formation during the process of folding.

At the Dufferin mine, in the Salmon River district, I saw a dome whose outcrop is barely 2000 ft. long, east and west. In other districts, such as Caribou, Mount Uniake, and Oldham, it is obvious, from the geological surveys of E. R. Faribault, that domes exist having a length of 2500, 2000, and 3000 ft., respectively. Quartz, in the shape of saddle-veins, has been concentrated at the cross-folds, where the nose of the dome plunges underground, but in no case, as

*Portion of a paper read before the Canadian Mining Institute, March 8, 1912.

far as I know, has it been exploited profitably at both ends of a dome. In the Dufferin the domical structure is exposed on the 300-ft. level, which follows a quartz vein known as the No. 1A. Here, as shown in Fig. 2, the east and west legs of the dome are 1300 ft. apart, while the north and south legs have a spread of only 200 ft. at the same level. Since Mr. Faribault's map was published, it has been ascertained by him that the anticlinal fold is not a single flexure, but divided into two saddles at its crest. Of these, the southern is accompanied by a succession of quartz veins, which have been exploited to a vertical depth of 300 ft. and then abandoned as unprofitable.

The 'saddles' of Nova Scotia are also remarkable for peculiar corrugations or crumplings of quartz, to which the name of 'barrel formation' has been accorded, because, when such a corrugated deposit is uncovered, it looks to the miner like the back or top of barrels lying in rows. The old woodcuts, appearing in a report by Silliman, indicate the appearance of such a lode as exposed in a large open-cut on the crest of a hill at Waverley. I went thither in August 1905, and saw enough to confirm the general accuracy of

plain. The first idea, adopted by some of the early observers, is that the quartz constitutes an integral member of the sedimentary series, that is, the silica that became quartz was deposited contemporaneously with the silt and sand that became slate and quartzite. According to this theory, the quartz underwent folding and corrugation with the enclosing rock, and was particularly plicated at the places where anticlinal movements crossed. This simple explanation is killed by the single fact that the crenulated veins cut across the bedding-planes between the slate and quartzite.

The next theory that may be proffered is that the quartz has replaced another mineral, segregated from the original sediment and distributed along bedding-planes or other lines affording passage to underground solutions. Calcite is prevalent throughout the region, and in association with the quartz; therefore it may have occupied the fractures in which the quartz is now found. Such calcite would have been crushed by the earth-movements, and thus it would be all the more easily soluble in silicious acid waters. This theory also lacks the support of evidence. It is true that although we cannot conceive a layer of quartz undergoing

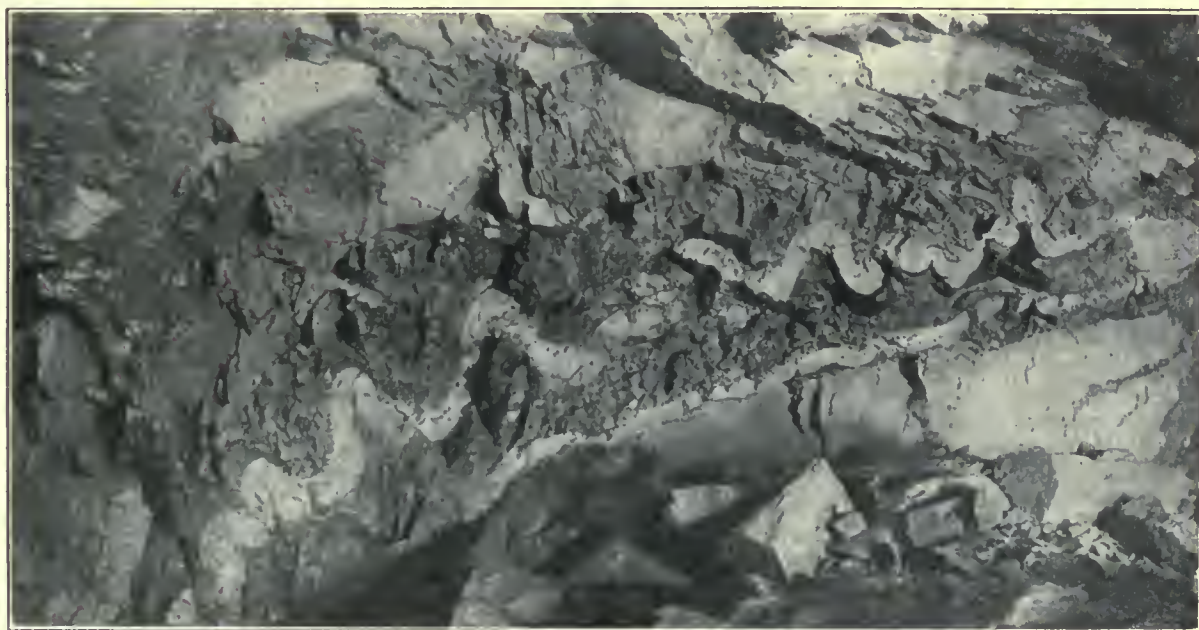

FIG. 4. THE BORDEN VEIN IN THE WEST LAKE MINE AT MOUNT UNIACKE.

his sketches. The corrugation, crinkling, or crumpling, as it has been variously termed, was most remarkable. As a technical term descriptive of this structure, I suggest 'crenation,' from *crena*, a furrow or notch, or the larger barrel structure, and 'crenulation,' from *crenula*, the diminutive of *crena*, for the smaller apparently serpentine threads of quartz.

While adopting the Latin derivative for the barrel structure, I deem it best to use the English word, 'furrow,' for the individual markings that constitute the appearance termed 'crenulation.' For the larger manifestation of the same structure it might, from an academic point of view, be desirable to use 'crenation,' but this is not necessary to a clear description, and may therefore be set aside for the present. 'Furrow' and 'crenulation' apply to the markings in the wall-rock, and not to the quartz filling them. The quartz is found in veins of varying continuity, and in shape reproducing the structure of the enclosing rock. Hence it appears crinkled, corrugated, crumpled, or serpentine, according to the degree to which the angles are curved. When enlarged, the bends make the so-called 'barrels'; when infrequent or individual, and especially when persistent, the 'barrel' becomes known as a 'roll.'

The origin of this beautiful structure is difficult to ex-

plain. The first idea, adopted by some of the early observers, is that the quartz constitutes an integral member of the sedimentary series, that is, the silica that became quartz was deposited contemporaneously with the silt and sand that became slate and quartzite. According to this theory, the quartz underwent folding and corrugation with the enclosing rock, and was particularly plicated at the places where anticlinal movements crossed. This simple explanation is killed by the single fact that the crenulated veins cut across the bedding-planes between the slate and quartzite. The next theory that may be proffered is that the quartz has replaced another mineral, segregated from the original sediment and distributed along bedding-planes or other lines affording passage to underground solutions. Calcite is prevalent throughout the region, and in association with the quartz; therefore it may have occupied the fractures in which the quartz is now found. Such calcite would have been crushed by the earth-movements, and thus it would be all the more easily soluble in silicious acid waters. This theory also lacks the support of evidence. It is true that although we cannot conceive a layer of quartz undergoing

³*Trans. Amer. Inst. Min. Eng.*, Vol. XXX, p. 32.

¹This term has been previously used by J. Edmund Woodman, in his paper on the 'Geology of Moose River Gold District'; Nova Scotian Institute of Science, 1903, Vol. XI, Part 1, pp. 18-88.

⁴*The Journal of Geology*, Vol. XVIII, No. 6. 'An Experimental Investigation into the action of differential pressure on certain minerals and rocks,' by Frank D. Adams.

that the erenulated veins traverse the bedding. Hence they could not so originate. If we recognize that the quartz does not lie wholly along the planes of bedding, then the problem of explaining the erenulated structure is not facilitated by imagining quartz to have replaced calcite, for any explanation that would suffice for one would be adequate for the other. Therefore this second theory does not carry us any farther forward. We dismiss it with regret.

The next theory is not so easily stated, but it is based on the observation that quartz veins exhibit a step-like or zigzag course in traversing beds of diverse texture and in crossing the cleavage, joints, or other structural inequalities of a homogeneous rock. Thus, at Bendigo, I noticed that the 'spurs' or cross-veins, which are mined profitably on a large scale, have a marked characteristic: they cross the sandstone almost at right angles to the bedding, but they tend to follow the cleavage of the slate. On turning to the description of the Bendigo goldfield, written in 1892, I find that I referred to this characteristic in the following words: "A quartz seam upon leaving a bed of sandstone and entering one of slate, invariably turns its dip in sympathy with the cleavage of the slate." To put it in another way: a fracture crossing a series of slate and sandstone (or quartzite) beds will cut right across the sandstone because it is of fairly uniform texture, so that it is as easily broken one way as another. The same fracture, when encountering a fissile rock, like slate, will find the path of least resistance along the cleavage rather than across it. Hence the fracture, in crossing an alternation of such rocks, will take a step-like or zigzag course.

If, next, we suppose the alternation to be repeated with greater frequency—if, in other words, we take a shaley sandstone marked by well developed cleavage—we obtain conditions favorable to a crinkly line of fracture.

This affords a clue, which appears to be confirmed by the significant fact that the erenulation, as seen in the Nova Scotian mines, has a pitch conforming to the line of intersection between the bedding and the cleavage. It appears to be dependent on a relation to the cleavage.

Crenulation is not unknown at Bendigo, although there it is not a dominant characteristic. On turning to my first paper on the Bendigo goldfield (*Trans. A. I. M. E.*, Vol. XX) I find two sketches illustrating this structure. One of these shows that the deposition of quartz has followed not only the lines sympathetic to the bedding but also a nearly vertical fracture along the antilinal axis, as well as another that shows some kinship to cleavage. We must remember that the shape of the quartz is determined by the nature of the receptacle that it occupies; even if we suppose it to have found space by replacement of portions of the country rock, we have to ascertain the nature and shape of the fractures along which it found a way when in solution. Veins of quartz vary in dimension and direction in accordance with the diverse texture and hardness of the rocks traversed by fractures precedent to ore deposition.

These fractures are various. The lines of weakness along the bedding-planes, especially such as separate a relatively soft from a relatively hard rock, a slate from a quartzite, for example, furnish obvious facility for rupture. Along these is deposited the quartz of the ordinary saddle-vein. Other things being equal, the crest of an antiline furnishes an opening or a tendency to open; the syncline does this also, but, while the principle of the arch tends to keep the antilinal fracture open, the dead weight of a trough-like depression or syncline tends to close it. Between the two bends, on the flanks of the antiline—which are also the reversed flanks of the syncline—the strata are compressed, the bedding planes are tight, and the least possible facility is afforded for the circulation of underground waters. Connection between the crests of the antilines is obtained by fractures that follow the antilinal axis, as in Nova Scotia, or by dikes that have been injected in the wake of regional dislocation, as at Bendigo.

In a region marked by folding the greatest intensity of fracturing is exhibited at the place of maximum plication. At Bendigo this is found at the apex of an anti-

line. In Nova Scotia it is found where the folds intersect, that is, where an antiline plunges in obedience to a transverse syncline: at the nose of a dome. It is there that the erenulation is most marked. Folding is accompanied by cleavage in fissile rocks and by jointing in those of granular texture. The main antilinal axes are characterized by a dominant cleavage, usually at a high and persistent angle. At the approach to the apex of the fold, and more especially at the place where the rock is twisted by cross-folds, the regional cleavage is dominated by a local radial fissility.

At the place of maximum flexure, where the cleavage dominates the bedding, any fracture due to regional movement will find a devious way. In part it follows the bedding or, at least, it confines its divagation to one soft bed—of slate; in part it responds to the invitation of the cleavage lines; in default of such assistance it traverses both bedding and cleavage, but not for long. A vein-fracture in one mine plays many parts. That was the lesson at Bendigo; that is the teaching of Nova Scotia.

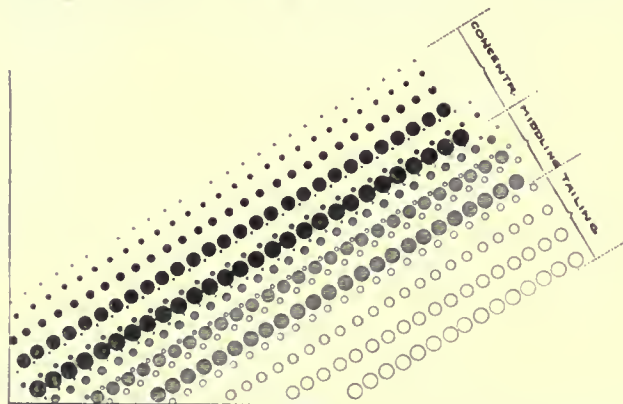

When the solutions containing both quartz and gold began to course along the fractures thus prepared, they were deposited wherever conditions were favorable, and after deposition they tended to reproduce the character of their abiding place. Thus I argue that they were precipitated along the bedding-planes, to form the simply tabular deposits that delight the writers of text-books; they likewise were laid down along the arches that gave us the symmetrical saddle-lode; they rested in cross-fractures that became the 'spurs' of Bendigo and the 'angulars' of Nova Scotia; and, finally, they found a way into the intricate and rhythmically crinkled passages prepared for them, where cleavage and bedding disputed for structural mastery.

Thus the erenulation may finally be regarded as the beautiful product of complex fracture due to cross-folds in rocks of uneven texture. The fissility induced by extreme plication has afforded a sinuous line of passage to rupture and to the quartz that subsequently healed the rupture. As originally formed, the veins were crooked, that is, they zigzagged in a sharply angular line. In the course of mineral impregnation they became rounded. Nature hates an angle as she abhors a vacuum. Time softens hard lines, is a poetic way of saying that chemical corrosion is most rapid where the largest surface is exposed to solvent action. The angles of the zigzag vein-fracture were filled with quartz, which, in the course of accretion from further passing solutions, replaced the crushed slate adjacent to it and slowly gained a rounded outline. On the 700-ft. level in the Gagnon mine, at Butte, I have seen boulders 5 or 6 feet in diameter, formed by the solvent action of water that has seeped along joint-planes in the granite. These were similar in origin to the boulders formed by erosion at surface, and were due to the sculpturing hand of chemical waters. Once rounded, the hard quartz bent the neighboring soft slate to its unyielding shape. Neither movement nor solution ceases underground at a given moment. Since the veins were formed, the continual shifting of loads of sediment, by transfer from mountain to river, from land to sea, has caused the disturbance of equilibrium that incites geologic unrest. This has been the cause of new fractures along which later solutions have found a patient way. We who see a vein in a mine today are apt to regard it as a finished product, brought to our attention at the close of a completed cycle of chemical and physical operations. We regard ourselves as full-stops in time. On the contrary, the whole of the period during which man has tenanted the earth barely punctuates the geologic record; ours is a brief phase synchronizing with a minute portion of the vast stretch of time during which the vein of ore has undergone successive change. Had we left it in the ground it would have undergone, in later eons, a further alteration. When we remove it with the pick and hammer we break the normal sequence of its development; we are for a brief moment the masters of forces that have operated since the dawn of creation.

Re-treatment of Table Middlings

By GELASIO CAETANI

The arrangement and distribution of the grains of sulphides and gangue on the deck of a reciprocating table has repeatedly been described by R. H. Richards¹, and is illustrated in the accompanying figure. The characteristic feature of this arrangement is that the grains of equal specific gravity will arrange themselves in order of size; the fine grains tend to advance toward the concentrate side of the table, while the coarser grains, on which the wash water has a stronger action, roll more rapidly over the inclined deck of the table, distributing themselves closer to the tailing side. Therefore all grains of equal specific gravity will arrange themselves strictly in accordance with their diameter. On the other hand, the heavy particles of sulphides will roll less easily over the deck than the lighter grains of gangue, and this, coupled with the progression

ARRANGEMENT OF MINERAL PARTICLES ON A TABLE.

imparted by the motion of the table, causes the minerals of different specific gravity to dispose themselves in bands. These bands overlap each other to a certain extent and, on account of this overlapping, some fine grains of the light minerals are intermingled with the coarse ones of the heavy minerals.

In a theoretically perfectly classified feed, this intermingling of fine gangue and coarse sulphide grains could not exist. This intermingling is the result and an index of imperfect classification of the feed, and it can be said that the band of middling on a table represents the zone where all the errors of classification have accumulated. In practice a perfect classification is not obtainable, therefore the middling from any table of the Wilfley type will contain, in addition to the grains of gangue carrying included sulphide, a variable amount of coarse and practically clean sulphide grains and some fine low-grade sand. Advantage ought to be taken of this characteristic nature of the middling while attempting to recover the free and included sulphides it contains.

Any material having the characteristics described above, I have designated as a 'counter classified' product,² for the reason that this product is exactly the contrary to that obtained by hydraulic classification, in which the small particles are found to be of higher specific gravity, and the coarse particles of lower specific gravity. Other machines, besides reciprocating tables, produce 'counter classified' products; an instance being the lutch discharge of Harz jigs operating an unsized feed.

It is evident that a 'counter classified' product is an ideal material for classification, and that a classifier will easily separate it into a discharge containing practically all the high-grade sulphides, and an overflow containing most of the fine gangue and a small amount of very fine free sulphide.

This is illustrated by the following analyses of the products separated by hydraulic classification from the middlings of reciprocating tables.

MIDDINGS OF COARSE WILFLEY TABLE CLASSIFIED BY CAETANI PIPE CLASSIFIER

(Tomboy G. M. Co.'s mill. Galena-pyrite-blende-quartz ore.)

	Weight, %.	Iron, %.	Lead, %.	Insoluble, %.
<i>Coarse Wilfley Middling.</i>				
Classifier discharge	34.10	11.90	1.15	7.6
Classifier overflow	19.50	7.20	0.80	32.8
<i>Fine Wilfley Middling.</i>				
Classifier discharge	20.70	22.50	6.6
Classifier overflow	13.25	6.25	48.2

Second series of tests:

	Weight, %.	Zinc, %.	Iron, %.	Insoluble, %.
<i>Coarse Wilfley Middling.</i>				
Feed to classifier	100.0	23.70	8.10	34.70
Classifier discharge	91.0	25.70	8.60	32.60
Classifier overflow	9.0	3.85	3.50	77.80
<i>Sand Wilfley Middling.</i>				
Feed to classifier	100.0	27.50	11.20	22.70
Classifier discharge	78.6	33.60	12.50	12.20
Classifier overflow	21.4	12.90	6.00	55.20
<i>Fine Wilfley Middling.</i>				
Feed to classifier	100.0	25.90	12.50	21.90
Classifier discharge	78.0	28.40	13.80	17.30
Classifier overflow	22.0	18.10	8.30	40.90

MIDDINGS OF COARSE CARD TABLES CLASSIFIED BY PIPE CLASSIFIER

(Bunker Hill & Sullivan mill. Galena-siderite-quartzite ore.)

Product.	Lead, %.	Iron, %.	Insoluble, %.
<i>Coarse Card Middlings.</i>			
On 60-mesh	26.00	26.25	3.20
On 80-mesh	17.15	30.70	3.40
On 100-mesh	13.30	32.25	3.90
On 150-mesh	8.85	32.95	5.30
On 200-mesh	5.80	32.70	7.80
Through 200-mesh	7.05	31.00	10.00
Direct assay	13.25	31.00	6.20
Classifier discharge	21.60	30.15	2.90
Classifier overflow	12.45	32.10	5.00

In certain instances this concentration of sulphides in the coarse spigot discharge of the middling classifier is so marked that this product becomes a concentrate of shipping grade. This is being done at the Tomboy mill.

This method of concentration by classification depends on whether a considerable portion of free, coarse sulphide grains is allowed to go into the table middling. This is the case when endeavoring to make a very clean concentrate. If, however, some of the higher-grade silicious middling is thrown in with the concentrate and the grade of the concentrate is allowed to drop, the table middling will contain a lower percentage of coarse sulphide grains and no shipping product can be expected from the classifier. In all cases, however, classification will produce a concentration of all the large grains of higher specific gravity in the coarse spigot discharge. By re-treating this product on tables it will be possible to separate a clean concentrate, and the table tailing will be found to contain practically all the material that requires re-grinding to liberate the included sulphides. The finer spigot discharges of the classifier and its overflow will yield, when fed to a table, some clean concentrate, and the table tailing will generally be found to be sufficiently low grade to be rejected.

In most mills the practice of classifying the middling is not followed, and this hybrid product is either directly returned to the table which has produced it (as when middling elevators are used on a Wilfley table), or it is sent to a second set of tables, on which it is concentrated a second time without previous classification. The middling represents a product that imperfect classification has rendered unsuited for good separation on a table, and to concentrate this material a second time without removing the source of difficulty is merely attempting the impossible.

In many mills the tonnage of middling produced is not sufficient to warrant the installation of a classifier and Wilfley tables, solely for the purpose of re-treating the middling. In such case it is advisable to return the mid-

¹Trans. Amer. Inst. Min. Eng., 38, p. 577; 'Ore Dressing,' p. 1475, etc.

²'Milling of Lead-Silver Ores,' *The Mining Magazine*, June 1910.

dling to the original classifier where this product will be again distributed to the tables according to size. The drawback of this method lies in the fact that the coarse middling often contains only a small amount of free sulphide particles, the rest being coarse grains containing included minerals which require to be re-ground before further concentration can be effective. The result of it is that these coarse grains of middling, by circulating over and over again from the classifier to the tables, will gradually accumulate until they take up a large part of the table capacity, and eventually are thrown off either in the concentrate or in the tailing, to neither of which do they belong.

A system followed in several mills is to send the middling directly to the re-grinding machinery, and, though this method often simplifies the general arrangement of the mill, it causes the sliming of a portion of the free sulphides and crowds the grinding machinery and the re-treatment tables with fine gangue which does not require further treatment. In mills with sufficient table capacity and sufficient fall for handling the table middling, it will always be advisable to subject this to close classification and secondary concentration, and in many instances it will be found that this system will produce a considerable amount of clean concentrate and low-grade tailing, and thereby increase the efficiency and capacity of the mill.

Workmen's Compensation in Great Britain

The British Compensation Act of 1906 is summarized as follows by the *Journal of Industrial Safety*:

Injuries Compensated.—Personal injuries by accident arising out of and in course of the employment which cause death or disable a workman for at least one week from earning full wages at the work at which he is employed. Compensation is not paid when injury is due to *serious and willful misconduct*, unless it results in death or serious and permanent disablement. Industries covered: "Any Employment."

Persons Compensated.—Any person regularly employed for the purposes of the employer's trade or business whose *earnings* are less than £250 (\$1216.63) per annum; but persons engaged in *manual labor* only are not subject to this limitation, or those whose employment is of a casual nature.

Government Employees.—The act applies to civilian persons employed under the Crown to whom it would apply if the employer were a private person.

Burden of Payment.—The entire cost of compensation rests upon the employer.

COMPENSATION FOR DEATH

(a) A sum equal to three years' earnings, but not less than £150 (\$729.98) nor more than £300 (\$1459.95) to those entirely dependent on earnings of deceased.

(b) A sum less than above amount if deceased leaves persons partially dependent on his earnings, the amount to be agreed upon by the parties or fixed by arbitration.

(c) Reasonable expenses of medical attendance and burial, but not to exceed £10 (\$48.67) if deceased leaves no dependents.

COMPENSATION FOR DISABILITY

(a) A weekly payment during incapacity of not more than 50% of employee's average weekly earnings during previous twelve months, but not exceeding £1 (\$4.87) per week; if incapacity lasts less than two weeks no payment is required for the first week.

(b) A weekly payment during partial disability, not exceeding the difference between employee's average weekly earnings before injury and average amount which he is earning or is able to earn after injury.

(c) Minor persons may be allowed full earnings during incapacity, but weekly payments may not exceed 10 shillings (\$2.43).

(d) A sum sufficient to purchase a life annuity through

the Postoffice Savings Bank of 75% of annual value of weekly payments may be substituted, on application of the employer, for weekly payments after six months; but other arrangements for redemption of weekly payments may be made by agreement between employer and employee.

Revision of Benefits.—Weekly payments may be revised at request of either party, under regulations issued by the Secretary of State.

Insurance.—Employers may make contracts with employees for substitution of a scheme of compensation, benefit, or insurance in place of the provisions of the act, if the Registrar of Friendly Societies certifies that the scheme is not less favorable to the workmen and their dependents than the provisions of the act, and that a majority of the workmen are favorable to the substitution. The employer is then liable only in accordance with the provisions of the scheme.

Security of Payments.—In case of employer's bankruptcy, the amount of compensation due under the act, up to £100 (\$486.65) in any individual case, is classed as a preferred claim; or where an employer has entered into a contract with insurers in respect of any liability under the act to any workman, such right of the employer, in case he becomes bankrupt, are transferred to and vested in the workman.

Settlement of Disputes.—Questions arising under the law are settled either by a committee representative of the employer and his workman, by an arbitrator selected by the two parties, or, if the parties cannot agree, by the judge of the county court, who may appoint an arbitrator to act in his place.

Three of the most important features of the act are:

(1) "Serious and willful misconduct" on the part of the injured person bars recovery of compensation only when the injury "does not result in serious and permanent disability or death." Thus the workmen's right to recovery is in inverse proportion to his care for himself and others. If an intoxicated fireman or engineer should cause a boiler to explode, demolishing the plant, causing death to the employer and serious injury or death to the engineer, besides the ruin of the plant, the employee or his dependents would be preferred creditors against the estate of the employer.

(2) By "a person whose employment is of a casual nature" is meant that a workman who may be doing a chance job for a man could not receive compensation, if he should be injured while performing his duty, while if he should be working for the man regularly, he could claim compensation. To illustrate this difference, suppose that a house-owner had his roof damaged during a storm, and he employed a carpenter to mend the roof, the carpenter job would be one of a casual nature, and, therefore, recovery of compensation would be barred by the act, in case he should be injured. Again, suppose the same house-owner employed a woman to come in and do the washing once a week, such a woman would come under the act, since her employment is not of a casual nature.

(3) "Arising out of and in the course of employment" is the wording of the act, which signifies that it makes no difference as to the locality of the accident, as long as the injured man was pursuing his employment. To illustrate, suppose that the house-owner had his house burned accidentally, and the servant lost her life while in the house, her dependents could claim compensation, since her death was one "arising out of and in the course of her employment," but if that same servant injured her eye, due to a fright caused by a bug flying in through the window, it would be held that, while it occurred "in course of employment," it did not "arise out of it."

According to Section VII of the act, masters, seamen, and ship apprentices of vessels registered in the United Kingdom, or the owners or managing owners, who reside in the United Kingdom, can claim compensation for injuries arising under the act. Also workmen employed by or under the Crown (except persons in the naval or military service) are included in the act.

Experiments With the Thiogen Process

By FRANK L. WILSON

At a lecture recently delivered before the Mining Association of the University of California, S. W. Young, professor of physical chemistry at Leland, Stanford Jr. University, gave a very interesting and detailed account of his Thiogen process and the results so far obtained. His remarks, in slightly condensed form, follow.

The gases and waste products issuing from the flues of roasters, blast-furnaces, reverberatory furnaces, and converters, are made up for the most part of flue-dust, SO_2 , SO_3 , CO_2 , and nitrogen in varying proportions. The main sources of these products are the roasters and blast-furnaces. The flue-dust is largely caught before leaving the stack, while the gases pass out into the atmosphere. The most troublesome of these gases are the SO_2 and SO_3 . The SO_2 , being but a small part of the gas, has not proved of importance, but the SO_3 issues from the stacks in large quantities and travels great distances. One method of present-

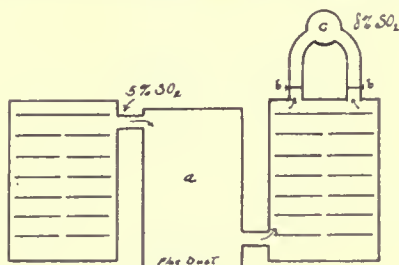

FIG. 1.

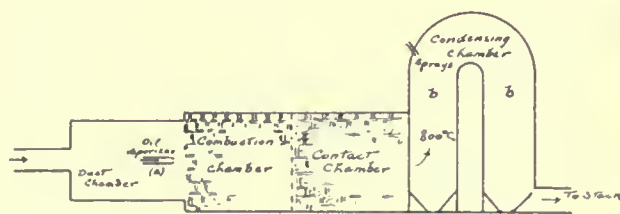

FIG. 2.

day practice is to dilute the gases by mixing with sufficient air to meet the requirements of the law before discharging into the atmosphere, and heretofore no attempt has been made to recover the sulphur as such.

The present sulphur supply is obtained from the sulphur wells of Louisiana, and the natural deposits of Japan, Sicily, and Mexico. At the present time sulphur is being discharged into the atmosphere from the stacks of different metallurgical plants (1000 tons of pyrite ore discharging approximately 800 tons of SO_2). To recover this sulphur it is necessary to have some reducing agent to combine with the oxygen of the SO_2 . Carbon has been tried, the SO_2 gas being passed over red-hot coke. This process was found to be expensive and only partly successful. In the Thiogen process an oil spray is used to furnish the necessary carbon, and the reaction is shown by the following equation:

Ordinarily the CO would reduce more SO_2 , as is shown by

but this reaction takes place very slowly. In the presence of a catalyzer, however, the reaction is accelerated. It has been shown by the Mannheim process that in the manufacture of sulphuric acid the reactions are accelerated by means of a catalyzer in the form of Fe_2O_3 . The SO_2 gases are passed over hot Fe_2O_3 .

and the Fe_3O_4 again reacts with the free oxygen in the gas

A suitable accelerating reagent was found in calcium sulphide. Potassium and other alkaline sulphides might be used, but calcium is the cheapest and the most infusible of them all, standing quite high temperatures. As a catalyzer the calcium sulphide acts as follows:

and in the presence of a reducing agent, as vaporized oil, the CaSO_3 is reduced to CaS

In laboratory experiments these reactions are rapid, especially so when iron salts are present in the catalyzer. No CO was formed, and all of the carbon combined with the oxygen to form CO_2 direct. The mixture of CH_2 and SO_2 may be passed over almost any calcium compound, as CaCO_3 or CaSO_4 , and the resultant compound is CaS. In case the gases contain free oxygen, this must be taken care of before the CH_2 will replace the oxygen in the SO_2 , and this difficulty presents the worst drawback to the process from an engineering standpoint. A suitable tempera-

THIOGEN PROCESS PLANT, CAMPO SECO.

ture must be maintained for the gas passing over the catalytic agent.

It is preferable to clean the gas as thoroughly as possible and concentrate it before allowing it to pass to the combustion chamber. An 8% SO_2 content has been obtained by passing the resulting gas products from one roaster through a large drum (a Fig. 1) to another similar roaster, the draft being controlled by means of dampers (b). The gas finally passes through the connecting flue (c) to the apparatus.

The roasters at Campo Seco, where this process is being tried experimentally, are of an old type, not constructed to control the amount of oxygen passing in so that all the admitted air may be utilized, and 8 or 9% gases are the best that can be obtained from them.

The vaporization of the oil is accomplished by the use of steam injected burners, as shown at a, Fig. 2. This spray of oil is directed into the combustion chamber, which consists of a checkerwork of brick, and a temperature of about 800°C. is obtained. Beyond this is a reaction chamber, similarly filled with a checkerwork of brick. This chamber is 4½ ft. square and 30 ft. long, and is more than able to handle the gases from the two roasters. The spaces in this checkerwork of brick are nearly filled with a mixture of equal volumes of plaster of paris and sawdust wetted with water, to which a small amount of iron salts is added. This mixture has the advantage that it decreases the amount of plaster of paris used and gives a porous mass. The sawdust burns out and the CaSO_4 reduces to CaS quickly, the mass shrinking so as to fill

about half of the space between the bricks. Condensing chambers are necessary to collect the sulphur liberated. Cast-iron condensers were found to be too leaky, and at present an inverted V-shaped pipe is used (see *b*, Fig. 2), each condenser having a sloping floor with a trap-door. Difficulties were encountered in this chamber. Any selenium, arsenic, or antimony compounds that the ore contains distill over and condense with the sulphur. To overcome this a low, broad, slightly inclined, condensing chamber can be used, in which water-sprays cool the gas below the boiling point of selenium and arsenic (about 750°C.), or about 500°C., the selenium, arsenic, and antimony being deposited on projecting tiles placed in the walls of the chamber for that purpose, and finally drawn off through traps in the lower corners. The sulphur, having a lower boiling point, passes on and is caught in the regular condensing chamber described above.

Tight construction is required throughout, and the brick walls so far used have been too porous to withstand the inward pressure of the air due to the vacuum caused by the draft up the stack. Leakage of air has been guarded against by means of sand sealing. Trouble also occurred through ends of the chambers being forced out, due to expansion of the brick, and it is hoped this will be overcome in a great measure by building the separate chambers independently and allowing for telescoping, using sand sealing to guard against air leakage inward.

Three trials have been run so far at Campo Seco. The first was largely to show the supervisors that the process was feasible. The apparatus used consisted of a 4-in. pipe connecting with the flue and discharging into an 8-in. pipe, 5 to 6 ft. long, in which the contact material was placed. A gasoline burner was placed at the junction of these two pipes and the necessary CH_4 and heat obtained. Leading from the 8-in. pipe, a 2-in. pipe discharged into a large iron drum. At a point in the drum above the 2-in. pipe a spray of water was allowed to play on the gases, the resultant liquid being tapped from the bottom of the drum. This resultant liquid showed free sulphur and was milky white in appearance. Connected with the drum by means of another pipe was a blower that drew the gases through the apparatus with considerable velocity and discharged the soot and the gas on a piece of corrugated iron. Analysis of this soot showed free sulphur. The escaping gas was nearly free from SO_2 .

The second trial was made about a month ago, and on a larger scale. There was considerable leakage of air and consequently considerable oxygen came in contact with the free sulphur and combined with it. Heat was generated by this combustion, and the temperature at the condenser was raised to slightly over 950°C. Analysis of the gas showed 5.6% SO_2 at the inlet and 0.2% at the condensing chamber, a decrease of 5.4%, or above 97% of the sulphur dioxide present.

On March 11 the present condensing chamber was ready and the apparatus tried (see Fig. 2). Trouble was encountered shortly after the burner was started. The temperature ran up beyond 1100°, and on shutting down it was found that someone had shut off the spray-water, and as a result the sprays were burned out and rendered useless. A tremendous draft was developed, due to the excessive heat. The present sprayers are an improvement over the former ones, in that they cause the spray to be thrown in all directions, thus cooling the gases more uniformly.

The cost of repairs cannot be estimated at the present time. Gases from the roasters have been passed for some time through the apparatus without settling out the flue-dust, but if the dust is settled out, the apparatus can run indefinitely without becoming clogged. Gypsum is not very expensive and the old contact material is not wasted, as it can be used in the smelting operations. Indicators are now being devised to register the percentage of SO_2 in the gas automatically, the supply of gas in turn being regulated by dampers placed at convenient points. Any excess oil burned will be taken care of by the CaSO_3 , and any excess SO_2 by the CaS .

Working Costs on the Rand

JOHANNESBURG CORRESPONDENCE

The problem of how to effectually reduce the working costs on the Rand is becoming every month of increasing importance. Two years ago the average working cost of ore per ton milled was 17s. 1d., when both the profits and dividends paid to stockholders attained their highest level. Since that date, not only has the average cost of working increased to the extent of over a shilling per ton, but the grade of ore milled has declined to the same amount, with the result that, despite the steady increase in the production of gold during the past two years, both profits and dividends have perceptibly declined. There are not wanting signs to indicate that those who control the mining industry are fully alive to the necessity of increasing the profits in order to maintain the confidence of stockholders, but there seems to be some difference of opinion as to the best methods to pursue in order to attain that object. One school advocates an artificial improvement in the grade of ore sent to the mill by selecting ore in the stopes to add to the profits, but, in addition to its other drawbacks, this always adds to the working costs. This method does not meet with general favor on the Rand, although there have been several notable converts made in its favor during the past six months, largely because the efforts at economy and improvement in methods of mining have not brought the anticipated relief to mining costs. That there is room for economy in Rand working costs, from the native laborer to the top of the administration, seems to be the prevailing opinion here, and it is possible that the growing cost of unskilled labor has more to do with the higher working costs than anything else. The blame for this must be fully borne by those who control the industry, who of late have not only been the means of one group of mines competing with another to obtain a full labor supply, but have displayed a wanton recklessness in giving labor agents contracts on such conditions as to render higher working costs inevitable. Then again, during the past two years there has been an attempt to introduce a cheaper grade of white labor into the mines, but its efficiency has been so low that in the long run it has been more expensive than trained, experienced, and more highly paid labor. A similar result has attended the introduction of a cheaper form of administration in that particular branch where experience and long training are so essential. The introduction of a lower-salaried and more numerous administration has resulted in a much increased salary bill, and drastic attempts have been made to bring down the wages by wholesale reductions of office expenses by dismissals. It is evident that the grade of rock sent to the mills on the Rand must on the average continue to decline, as no artificial efforts can be made on a sufficiently large scale to prevent it, but the decline will be so gradual that no difficulty should be experienced in making a compensating reduction in the working costs. Despite the continued development of the country and the growing demand for native labor, a revision of wages and conditions is absolutely necessary if mining costs are to be reduced. Little benefit seems likely to accrue from encouraging the employment of a cheaper and less efficient supervising staff, from the miner to the administrator. Some benefit must result from the costly and unnecessary aim at uniform monthly results being abandoned, adoption of closer sorting, and the placing of underground mining operations on similar lines to those which in other mining fields are found essential to reduce working costs to a minimum.

COPPER MINES at Ferrobamba, in Peru, 40 miles west of Cuzco, are owned by Ferrobamba, Ltd. Tests made by Claude Vautin show that both the oxidized and sulphide ore can be concentrated, with a saving of 74%, to a product assaying 30% copper. The company owns several mines and the total amount of ore available is stated at 7,500,000 tons.

Matanuska Valley Coalfields, Alaska

By G. C. MARTIN and F. J. KATZ

*The coal of the Matanuska valley is of three kinds; anthracite, high-grade bituminous, and low-grade bituminous. Of these, only the last two have been found within the area mapped in detail in the investigations here described. The anthracite occurs farther east and has been described in earlier reports. The high-grade bituminous coal occurs on the south side of the Matanuska, east of and in the vicinity of Coal creek, and on the north side of the river in the valleys of Chickaloon and Kings rivers. The low-grade bituminous coal is known in the valleys of Young, Eska, and Moose creeks.

The high-grade bituminous coal is fragile and soft, like most coal of this kind, and the beds show the effects of having been severely crushed and at many places are without any well defined bedding planes or planes of fracture. The friability of the coal is such that it will probably not stand shipment without being badly broken. This is not so great a detriment as might at first seem, because many of the beds contain so many impurities that the coal from them ought to be crushed and washed. It is, therefore, highly probable that much of this coal will be used in the manufacture of coke, a purpose for which lump coal is not desirable. Coal which possesses coking properties, as much or all of this coal does, can be burned as slack about as well as in lumps, for the slack coal when thrown into the furnace will fuse and cake, thus preventing loss of coal through the grates.

The low-grade bituminous coal on Moose, Eska, and Young creeks is on the border line between bituminous coal and black lignite. It is harder than the higher-grade coal farther east. Many of these beds have not been crushed, and a larger proportion of lump coal can probably be obtained from them in mining than from the coal beds described above. This coal possesses no coking properties and will probably be used under stationary or locomotive boilers. It is not so good for this purpose as the coal from the east end of the field, but, because the latter is well suited for the manufacture of coke and for use as smithing and naval coal, it will command a higher price and thus probably leave a lower-price market for the poorer coal farther west. The low-grade coal can probably be mined and shipped more cheaply than the high-grade coal. The two kinds of coal will, to a certain extent, be non-competitive, each having its own special market.

Chemical Analyses and Tests.—The following table in-

cludes characteristic analyses of coal from various parts of the area. Sample 1-1910 was taken during the investigations, here described. The other analyses have been published in Bulletins 289 and 327, and represent samples collected in 1905. All the samples except No. 1 and 2 were obtained from surface prospects or from outcrops, and were consequently somewhat weathered. Samples 1 and 2 came from an adit at a distance of 43 to 58 ft. from the mouth and probably under about 25 or 30 ft. of cover.

Coking Qualities.—A rough test of the coking qualities of the coal from adit No. 2 on Chickaloon creek was made during the summer of 1905 by coking a large pile of coal under a covering of stones and dirt. The resulting coke was hard and firm and had a good ring and a good texture. The test indicated that by proper treatment a coke of satisfactory grade can be produced. No further tests have been made by members of the Geological Survey. The analyses indicate, however, that the high-grade bituminous coal of Chickaloon and Kings rivers and on Coal creek is probably, at least in part, coking coal, and that the coal in the west end of the district, on Moose, Eska, and Young creeks, is low-grade bituminous and is probably all non-coking coal.

MINING CONDITIONS

Mine sites should be selected only after a careful study of local conditions accompanied by drilling. The selection of a site should be governed by the accessibility to the railroad and by the structure of the rocks. The latter should be determined in detail for each property by careful drilling or otherwise in order that the mine may be opened at such a point that the underground haulage of the coal and the disposal of the mine-waters may be accomplished at a minimum of expense.

Although many of the coal beds outcrop at the surface, the outcrops dip for the most part at steep angles. Few if any localities have been found at which it would be possible to open an extensive mine on the outcrop of the coal bed. The amount of coal above the general drainage level is not great, and it will be necessary from the beginning of mining to sink shafts or slopes to considerable depths. When any large mines are opened, it will probably be found desirable to sink shafts to the coal beds at considerable distances from their outcrops.

Local Supplies.—The local region will furnish none of the supplies needed in coal-mining except timber. Everything else will have to be shipped from outside of Alaska. The development of this field on a large scale will consequently probably involve the building up of other industries, such as establishments for the manufacture of mine cars and other machinery and mine supplies.

Underground Water and Gas.—In any large mines which

*These analyses were made by F. M. Stanton on the same samples as those with corresponding numbers in the preceding table. The differences in proximate analyses are due to the fact that the samples dried somewhat in the months which elapsed between analyses, and that somewhat different methods of analysis were used. (See Bull. U. S. Geol. Survey No. 290, 1906, pp. 29-30.)

*Abstract from Bulletin 500, United States Geological Survey.

are opened in this region it will be necessary from almost the beginning of mining to pump or hoist mine-water. It is not believed that it will be possible to open any large mines having natural drainage. The amount of underground water which will be encountered will probably not be great, unless the mines are opened on the outcrop. Precipitation in this region is so slight that large amounts of water can get into the mines only from the streams. If ordinary precautions are taken to prevent streams from breaking into the mine openings the mines ought to be fairly dry. The heavy cover of gravel which exists at the lower altitudes throughout most of the Matanuska valley will cause certain dangers in mining. Unless the depth of the gravel at different points and the shape of the underlying rock floor are determined by drilling there will be danger of the mine workings breaking through the surface of the rock into the gravels. The gravels probably carry large amounts of water in some places and serious accidents might thus result. Gas will probably be a serious problem in local mining from the very start. The experience of the few small adits which have been driven indicates that these coal beds will yield large amounts of dangerous gases. Some provision ought to be made in advance of mining for the enforcement of suitable regulations for protection of the miners and the mines against gas explosions.

Effect of Intrusive Rocks.—Intrusive rocks are known to be present in abundance and in large masses throughout the greater part of the area of coal-bearing rocks, except in the valleys of Moose and Eska creeks, where they are so small and are much less numerous than farther east. In conclusion, it must be stated that the presence of intrusive rocks in the coalfield introduces factors that make an undetermined percentage of the coal areas of very doubtful value. The size and distribution of these intrusive masses beneath the surface, as well as at the surface in the area of scanty outcrops, cannot be determined without underground exploration. The effect of the smaller intrusive masses on the coal depends on the extent to which these masses have been intruded into or along the surfaces of coal beds. Where the intrusive mass is in contact with the coal, the coal is worthless, but where it is a few feet away the quality of the coal is probably unimpaired, or may even be improved.

Effect of Folding and Faulting.—The steep dips and complex structure of much of the coal areas introduce serious problems in coal mining and call for careful investigation of the structural conditions of each individual tract before the development of mines is attempted. It is believed that areas will be found in which the difficulties of mining, due to structure, will not be serious. Both Castle mountain and Wishbone hill are of fairly simple structure, so that, if the coal beds persist beneath the conglomerate and if the coal-bearing rocks were not folded before the conglomerate was laid down, mining should not be difficult, at least so far as structural conditions are concerned. It may perhaps be assumed to be probable that the structures of the entire valley are of the same general type as those known in the areas of the conglomerate. If this is the case, there are probably large areas in which the structure will permit the mining of the coal. This condition is not, however, positively known, and the character of the structure must be regarded as a problem to be solved by underground exploration before the feasibility of mining at a profit of the coal of any particular tract can be demonstrated.

A RECENT consular report states that Butusoff, a Russian government mining engineer, is making a detailed examination along the banks of the Iman river, a tributary of the Ussuri. Results show that this territory is likely to become a field for large gold-mining undertakings. At present this district is the chief point where colonization is being concentrated. In connection with reports of discoveries of various mineral deposits along the Amur railroad, the Council of Ministers has decided to apply to the Duma for appropriations to organize surveying and geological stations along the entire railroad. Geological re-

searches of this region by parties of the Amur Expedition cover the whole line of this road from the northwest Transbaikal to Khabarovsk. The 'expedition' came to the conclusion that this region is of great importance, owing to its richness in minerals. There are reasons to believe that gold mining will develop in many places along the Yablonoi mountains, in the valleys of the Urka, Omutnaia, Urishi, and Oldoi rivers, and more especially in the valleys of the Kerak and Urkan. In the central and eastern parts of the railroad region large deposits of lignite were discovered, and they are thought to be valuable as they are near the line. Valuable iron deposits have been discovered near the Amur river.

Retention of Gold in a New Mill

By H. A. WHITE

*It may be interesting to briefly enumerate some of the sources of short returns in the first month's output of a new modern plant. Beginning at the mortar-box, where some little concentration takes place; the launder to the elevating plant picks up a little gold in any small crevices that exist; the tailing wheel or pumps, especially the former, have been known to gather quite a rich coating; the tube-mills have been known to yield as much as 500 oz. of gold upon removal of the lining when worn out, and even silex liners can easily accumulate 200 or 300 oz. of amalgam. Besides the tube-mill plates, already discussed, the succeeding launders and traps will not yield their full share to the first clean-up. If in addition to these sources it is considered that all the rock crushed cannot be completely treated in the time, that a fair amount of gold is in the working solutions, that a large amount of partly coated zinc must be left in the extractor-boxes, that new furnaces and pots absorb some gold, and that some valuable by-products formed are not immediately treated, it is clear that the usual statement, to shareholders is considerably more than mere soothing-syrup. Indeed, considerable capital is necessarily locked up in this way, though this is seldom provided for in the estimates framed. I agree that liquid amalgam may be the means of conveying gold into minute cracks in the retorts; but where suitable trays are used no overflow can take place, and in such cases the retort will not be found to contain much gold, though the assay figures certainly warn us to cut out a piece for assay and not to rely upon appearance only. I would add, however, that at the Co-operative Smelting Works rich bonanzas are not found, and though gold content of the retorts bought is not taken into account, no unmanageable surplus of gold is found in the outputs. In fact, the manager, after a good deal of experience in breaking up old retorts, depreciates any enthusiasm about further supplies.

The fact that heat enormously increases the fluidity of most liquids has a considerable bearing upon this subject, and it is very instructive to examine a brick from the bottom of the ordinary furnace used in the lead smelting of zinc-gold slime. The minute cracks, visible only under the microscope, are yet filled with metallic lead; for though the pressure was small the lead was red-hot, with a corresponding decrease of surface tension and viscosity. A similar pressure of cold mercury would not so penetrate the brick if applied for years on end. It is a well known fact that a filter-paper moistened with such a liquid as paraffine is impervious to water, and if someone could apply this principle and discover a liquid with which the bottom of a pan-furnace might be soaked, thus avoiding the infiltration of gold-bearing lead and so evading a tiresome source of absorption of that precious metal, he would be performing a valuable service.

A CONCESSION to develop placer gold ground along the Santa and Chuquicana rivers of Peru has been obtained by John Bryson and Frank Klepetko, and an examination of the deposits is in progress.

*Excerpt from *Journal* of the Chem. Met. and Min. Soc. of S. A.

The Early History of Cupellation

By R. C. BENNER and M. L. HARTMANN

The process of cupellation, or the separation of the precious metals from lead and other impurities by fire, was known to the ancients. Early chemistry treated chiefly of the properties of the metals and their behavior when subjected to high temperatures. Metallurgy then ranked as one of the most learned sciences. In proof of the antiquity of man's knowledge of the purification of metals by fire, the following quotations from the Bible have been cited by James Napier, in 'The Ancient Workers and Artificers in Metal,' London, 1856:

"For thou, O Lord, hast proved us: thou hast tried us as silver is tried." Ps. lxxvi, 10.

"Take away the dross from the silver and there will come forth a vessel for the finer." Prov. xx, 4.

"Behold I have refined thee, but not as silver: I have chosen thee in a furnace of affliction." Isaiah xlvii, 10.

"And I will bring the third part through the fire and will refine them as silver is refined, and will try them as gold is tried." Zech. xiii, 9.

"Surely there is a vein for the silver and a place for the gold where they fine it." Job xxviii, 1.

But perhaps the earliest known reference to the actual cupellation process is made in a poetical passage in the Scriptures in which David implied the common existence of this process:

"The words of the Lord are pure words, even as silver tried in a furnace of earth, purified many times." Ps. xii, 6.

Napier says of this reference: "Here, we observe, David is not satisfied with saying that the word of the Lord is as pure as silver, tried and purified several times. He wishes to represent the most perfect state of purity. Consequently he descends to a particular method and says, 'Tried in a furnace of earth.'"

This distinct reference to an earthen furnace leads naturally to the conclusion that different methods were known and practised, and that the earthen furnace was considered best. Whether, as now, burned bones were used in making this earthen cupel, is not indicated, although bone-ash is not essential to the operation. Other earthen vessels have been used, but it would not be inconsistent with the common practice of those times to have used bone-ash, since we find that this substance was frequently used in the arts at that time. This is indicated by the passage, "I will not turn away the punishment thereof because he burned the bones of the king of Edom into lime." Amos ii, 1.

Other Scripture references cited by Napier (reference cited) and by W. H. Pulsifer ('Notes for a History of Lead,' New York, 1888, p. 136), in which the application of the cupellation is readily seen, are given below:

"Son of Man, the house of Israel is to me become as dross: all they are brass, and tin, and iron, and lead, in the midst of the furnace; they are even the dross of the silver. Therefore thus saith the Lord God; because you are all become dross, behold, I will gather you in the midst of Jerusalem. As they gather silver and brass and iron and lead and tin into the midst of the furnace to blow the fire upon it, to melt it, so will I gather you in mine anger and my fury and I will leave you there and melt you. Yea, I will gather you and blow upon you in the fire of my wrath and ye shall be melted in the midst thereof." Ezek. xxii, 18-22.

"Thy silver is become dross . . . I will turn again my hand upon thee and purely purge away thy dross and take away all thy tin." Isa. i, 22-25.

"They are all brass and iron: they are corrupters. The bellows are burned, the lead is consumed of the fire, the founder melteth in vain: for the wicked are not plucked away. Reprobate silver shall men call them." Jer. vi, 28-30.

Pliny is the earliest writer who attempts to give any detailed description of the process. However, his descrip-

tions are vague and inaccurate, and are of little value. Pulsifer, in his 'History of Lead', gives a detailed discussion of the works of Pliny, as well as of some more recent writers, relating to cupellation, some of which are as follows: According to Leger,¹ this metallurgical process was commonly known in the East and practised before the time of Cyrus (600 B.C.). Cupellation was not practised in the West until much later. Agathareides² describes the process of purifying gold by melting it in an earthen pot, together with lead and tin, to which barley, bran, and salt had been added. The fire, he says, was kept up during five successive days. Strabo³ refers to cupellation when he says that the silver ore from the mine was washed five times, the dregs were then selected, and the lead being poured off, the silver was obtained pure. He describes the silver furnace as being constructed so that the pestilential vapors of the lead were raised and carried off. The use of lead in refining gold is mentioned by Theognis,⁴ who lived in the sixth century, B.C.

Evidences of the practice of this method of refining argentiferous lead are abundant in the ancient mining districts of the Old World. Near Cartagena, Spain, pigs of lead of undoubted Roman smelting have been found, with cakes of silver lying near them. In the province of Barcelona great heaps of litharge have been discovered near the site of an ancient furnace. In the many ancient camps of France, evidences are abundant of this method of separating silver from argentiferous lead.

Remains of the ancient cupellation furnaces have been discovered near Almeria,⁵ Spain. Quantities of litharge have been found mixed with scoriae near old furnaces in Greece. Geber⁶ understood the process of cupellation, and Theophilus, who wrote in the eleventh century, describes minutely the method of preparing the crucible or cupel for the purification of the silver, and with careful detail gives directions for conducting the process. Agricola⁷ describes a smelting-house with the necessary apparatus for the separation of silver from lead by cupellation, and illustrates his description with wood-cuts, in which the smallest details are treated in the most painstaking manner. The cupellation furnace was much like those in use in Germany today. The blast was furnished by bellows operated by a water-wheel, the iron cover or hood was removed or put into position by a crane provided with a system of gears, the power being supplied by men working a crank-shaft.

The native Peruvians⁸ seem to have independently discovered this metallurgical process. They made 'souls' of clay called *guayras*, in the shape of flower pots, with many holes in them. These were filled with a mixture of ore and charcoal, carried to the mountains, where advantage of the wind currents could be taken, and there fired. The product of this fusion was further refined at their homes, the blast being secured by small hand bellows. Gracilaso de la Vega⁹ describes the Peruvian method of recovering the silver from its ores as follows: "The silver for the most part is extracted from the 'Hatun Potassi', in the melting of which they first found great difficulty; for, not being able to run, it burned away or evaporated in smoke, of which the Indians could not penetrate the cause or discover a remedy. But as necessity and covetousness make men ingenious and contriving, so, particularly, the Indians were infinitely industrious to find some way to melt their gold and silver. At length, after many experiments, they happened to try melting a baser sort of metal, which the 'lesser potassi' produced, consisting for the most part of lead mixed with silver, the which being more easily melted and run, and when put in the melting pots, together

with the fine gold and silver, would immediately cause them to melt and dissolve; for which reason the Indians gave it the name *curuchee*, which signifies anything that dissolves." This was the first melting, and was conducted in the mountains; the product was taken to their houses, where it was subjected to a second melting, when, by the use of the blowpipe, the lead was completely oxidized and the silver recovered.

The natives of India were acquainted¹⁰ with the process of cupellation three hundred years ago. Digging a hole in the ground, they worked up a composition of moist ashes with which they plastered the cavity, making a sort of a combined cupel and furnace in which they fired the mixture of lead and ore. The operation was repeated until finally the silver was recovered. Little progress was made during the time of the alchemists in the methods of refining precious metals, but Geber gives a complete description of the process of cupellation, which he states was hastened by the addition of saltpeter, by which impurities such as copper and tin were removed. After the alchemistic period had passed, much attention was given to the working of gold and silver ores, and the processes were greatly improved. At this time quantitative determinations of gold and silver by the cupellation process were coming into use. The use of the balance was made obligatory by law in all cupellation and cementation processes in order to prevent fraudulent practices. In the phlogistic period, quantitative determinations were developed, although few changes were made in the metallurgical operations connected with gold and silver. Since then the process has been steadily developed until it has reached its present state, although the essentials of the operation are the same as the ancients used.

Patent Laws of the United States

At a meeting of the Inventors' Guild, held November 24, 1911, the following resolution was adopted:

Whereas, The Constitution of the United States provides: "The Congress shall have power to promote the progress of science and useful arts, by securing for limited times, to inventors, the exclusive right to their respective discoveries"; and

Whereas, This constitutional provision was intended to obtain for the benefit of the Nation the publication of every new and useful invention in such full, clear, concise, and exact terms as to enable any person skilled in the art or science to which it pertains to make, construct, compound or use the invention, after the limited time for which the exclusive right is secured to the inventor by patent; and thereby to secure for the Nation the great benefit which, all experience shows, results to a Nation from publishing inventions, in contradistinction to following a policy which would tend to encourage trade secrets, monopoly, and trade combinations, which minimize the value of inventions to the Nation; and,

Whereas, A patent is in effect a contract between the Government and the inventor by which the Government, in consideration of the right to publish the invention for the benefit of the Nation, agrees that in return for his satisfactory disclosures of his new and useful invention under reasonable conditions, to be determined by the Government, it will secure the inventor for a limited time in the exclusive right to his new and useful invention; and,

Whereas, An inventor, after having performed his part of the contract by having made proper disclosure of a new and useful invention to the United States Government officials, is frequently subjected to unreasonable delay, expense, and injustice before obtaining his patent, and after having obtained his patent is not equitably secured in his exclusive right as the Constitution intended that he should be secured in return for his disclosure in good faith of his new and useful invention; and as a consequence of this unfair treatment of inventor patentees, the United States is not obtaining, in the degree that it should, the

National benefit of the best inventive work of its many able inventors; and,

Whereas, The United States patent system has been evolved to its present condition without proper consideration of the rights of the Nation, and of the inventors, who are the two real parties at interest, but on the contrary has been developed to its present condition almost entirely as the result of suggestions from persons who do not occupy the position of one of the parties to the contract which every patent represents; and who do not suffer damage from the delays, complications, injustice, and expense characteristic of the United States patent system and the United States Courts which hear patent causes; said damage being borne principally but indirectly by the Nation and to a lesser degree, but directly, by the inventor-patentees; and,

Whereas, It is a well known fact that modern trade combinations tend strongly toward constancy of processes and products, and by their very nature are opposed to new processes and new products originated by independent inventors, and hence tend to restrain competition in the development and sale of patents and patent rights; and consequently tend to discourage independent inventive thought, to the great detriment of the Nation, and with injustice to inventors whom the Constitution especially intended to encourage and protect in their rights; and,

Whereas, Under existing methods of trying patent cases, an inventor-patentee of average means could not, at his own expense, carry to a conclusion an average patent litigation against a wealthy opponent, and therefore a few wealthy concerns usually acquire nearly all important patents in their field, to the great damage of the Nation because of the restraint of competition and because of the resultant tendency of such inventors to seek protection for their invention by trade secrets or else to cease inventive work; and,

Whereas, Efficient protection by patent of new and useful inventions would offer to the average American manufacturer one of the best methods of meeting foreign competition, and would, in addition, improve quality, reduce first cost, and stimulate fair competition, with resulting benefit to the entire Nation;

Resolved, The Inventors Guild, composed exclusively of independent and experienced inventor-patentees, does hereby respectfully ask the attention of the President of the United States to the urgent need of reforms in the Patent Office and also in the Courts which hear and decide patent causes; and hereby requests the President to recommend to Congress the advisability of appointing a committee to confer with experienced and representative inventors with the object of promptly accomplishing such reforms as will result in more effectively carrying out the intention of the Constitution; and to supplement such recommendations by such executive action as in his judgment seems likely to assist in accomplishing the needed reforms.

ORSK GOLDFIELDS, LTD., has now made arrangements to work its Kolehan property in its own name, being the only foreign corporation to receive permission to work in the prohibited zone. The chief features of the work accomplished during 1911 have been the transport and construction of the 7½-cu. ft. dredge and power plant, the trial run of the dredge, and the operation of the stacker-scow plant. The dredge, which operated intermittently for 433 hours between October 25 and December 5, extracted gold to the value of £2750 from 47.089 cu. yd. treated. The operating costs were approximately 6d. per cubic yard. The Pokrovsky plant, which operated from May 14 to October 18, extracted gold to the value of £24,155 from 88,654 cu. yd. treated, or 5s. 5¼d. per cubic yard. The operating costs having amounted to 9½d. per cubic yard, C. H. Munro has recommended, and the board have agreed, that this stacker-scow plant shall be converted at the end of the coming season into a 3½-cu. ft. dredge, at an estimated capital outlay of about £9000. Mr. Munro estimates that this conversion will reduce operating costs to 5d. per cubic yard. He also estimates the amount of ground at present available for dredging at 10,000,000 cubic yards.

Sintering and Briquetting of Flue-Dust

By FELIX A. VOGEL

*Flue-dust, to most blast-furnace operators, means a troublesome by-product, the formation of which should be curtailed, if not eliminated entirely. However, with the increasing use of fine ores, larger furnaces, and high-pressure blast, the production of flue-dust is constantly increasing, and amounts annually in the United States to from 3,000,000 to 3,500,000 tons, an exceedingly high tonnage, of which, in the iron industry, a large part has been discarded as valueless. The first efforts were to re-charge the flue-dust into the furnace, either by moistening it down with an excess of water, or mixing it with clay to form balls or pulp, or treating it with lime-water. These methods have been practically discarded, as they failed to produce the desired result. To recover, in the blast-furnace, all the metallic content of the flue-dust, the following conditions should be complied with:

1. The dust should be agglomerated into lumps about the size of furnace-coke, so that it will help to carry the burden and facilitate the flow of the gases.

2. The agglomerated material should be strong enough to carry the burden without disintegrating; it should be heavy so as to decrease its volume, and it should be sufficiently porous to permit the furnace-gases to penetrate fully. Under no condition should the surface be glazed.

3. It should contain all of the valuable constituents of the dust, such as coke, iron ore, lime, etc.

4. It must stand handling, without undue breakage, and should not produce more than 5% of dust.

5. It must stand the weather.

6. It must not disintegrate in the blast-furnace before being greatly or totally reduced.

7. It must submit to easy reduction without requiring additional fuel.

8. It must not contain substances detrimental to blast-furnace operations.

9. Its cost of production must be low.

Iron blast-furnace operations, by the use of such agglomerated material, will profit by:

1. Regular steady operation.

2. Increased burden, increase in the yield and metal produced.

3. Decrease in the consumption of coke.

4. Decrease in the production of flue-dust.

5. Decrease in the cost of producing pig iron.

In order to obtain these results, American and European metallurgists have followed two different lines. In the United States it has sufficed to save the iron content only (though not in the best possible form), while abroad the endeavor has been to make a high-class product which would meet all the conditions above enumerated.

A number of processes have been evolved in the United States, generally known as agglomerating and sintering processes. They are based on fritting together the particles of ore by heat, the binding action being due to the formation of silicates, mostly of iron. When the coke has not been eliminated mechanically from the dust, it is burned out, leaving ashes in the agglomerated material, which increases the formation of silicates of iron or glazing material. In some cases, however, more fuel is added to the flue-dust, which, naturally, further increases this drawback. The nodulizing process, the oldest process in the United States, has been in successful operation for a number of years. Flue-dust is treated either directly, or it is previously submitted to a magnetic separation to eliminate coke and lime. This is done to facilitate the subsequent nodulizing operation, which is carried on in a slowly rotating cement-kiln from 80 to 120 ft. long.

*Preliminary edition of a paper presented before the American Institute of Mining Engineers, New York meeting.

From 200 to 300 lb. of finely powdered coal is used per ton of finished material, the coal being blown into the kiln. Gas and oil have also been tried with more or less success. The heat produced is considerable, and difficult to control, the semi-soft material formed consisting of iron ore particles and slag, which, by the revolving action of the kiln, is balled together in nodules of various sizes—from a pinhead to that of a cannon ball—which are usually quite dense, often fused, and glazed. They contain from 60 to 67% of iron, which makes them quite attractive from the furnace-man's point of view. To make nodules, an elaborate and expensive plant is required, the operation of which is more or less difficult and costly.

The Huntington-Heberlein pot process, which has been used with good results in the roasting of pyrite cinders, has been recommended for the fritting of flue-dust. The resulting fritted material is of more or less cellular structure. However, this would not be an advantage, as the surface would be largely glazed, rendering it impermeable to gases, and would have to be removed in the blast-furnace at about smelting heat. The process is somewhat simple, requiring stationary iron pots fitted with a perforated false-bottom through which the air is blown into the charge. The equipment is cheap; the operation, however, is not continuous, which makes it expensive.

The Gröndal briquetting process has also been applied to flue-dust. The flue-dust, either moistened, or after the elimination of the coke and stone, is pressed into bricks which are subsequently fritted at high temperatures. To facilitate the operation it was found necessary to eliminate the coke; this, however, increases the cost. The separated coke is of little value, since it contains many impurities. The presses used are ordinary brick-presses. The bricks are carefully placed in layers on ears, which are run into long kilns about 170 ft. long, where they are submitted to high heat, gas being used for the purpose. The platforms of the ears are built of firebrick and form the bottom of the kiln. The highest temperature, about 1300° or 1400°C., is reached in the centre of the kiln, the highly-burned briquettes working gradually toward the cooler end of the kiln, where they are finally unloaded. The operation lasts about 7 hr. The resultant briquettes contain 65 to 70% of iron with practically no impurities, these having been eliminated. No ashes are left by the fuel. The briquettes are only slightly fritted, are very porous and friable, and make a high-class material for use in an open-hearth furnace. The manufacturing of Gröndal briquettes is expensive, necessitating a costly plant, which has a limited output. A ton of flue-dust will produce about two-thirds of its weight in briquettes.

Quite recently the Dwight-Lloyd process has been applied to the sintering of flue-dust. The material is submitted to internal combustion in layers of from 5 to 7 in. thick. It is fed on an endless conveyor formed of iron pallets or grates. After the fuel therein contained has been ignited by means of a gasoline torch, or some other device, the air is drawn through by suction. The operation lasts about 20 minutes. A good deal has been published of late in regard to this process. It is claimed that the required plant is not costly, while the operating expenses are considerably lower than in the previous process. The resultant sintered material is not homogeneous and, while a large portion of it is of cellular structure, it is glazed on the surface, which makes it quite difficult to reduce in the blast-furnace.

The Greenawalt process uses much the same apparatus as the Heberlein pot, but air is drawn through the charge similarly to the Dwight-Lloyd process. The sintered material from these various processes is expensive on account of the loss of carbon and, with the exception of the Gröndal briquette, is not of good physical structure and is usually glazed on the surface. The briquetting of flue-dust has been more practised abroad than has the sintering.

In the lime process the flue-dust is mixed with from 5 to 10% of hydrate of lime, and, after briquetting, the material is exposed to the air for a certain length of time, so that a carbonate is formed which is the binding medium.

This binder will eventually act as flux and replace a certain amount of limestone. The process, while having decided advantages, is quite cumbersome and costly, as the briquettes must dry from two to four weeks under cover. The Pioneer process uses sulphide pitch (obtained from the sulphide pulp mills) as a binder. It is an organic substance, rich in carbon and hydrocarbons, which will burn readily and thus increase the calorific value of the material. The flue-dust is pressed into briquettes with from 4 to 8% sulphide pitch; they are quite hard and give fair results, but the process is expensive. The Ronay process does not use a binder. The flue-dust is submitted to a very high pressure in a specially constructed type of hydraulic press; the resulting briquettes can be handled immediately, and have proved very satisfactory. The process requires an expensive plant, however, increasing the operating cost.

The Schumacher process does not use what may properly be called a binder, but is based on the latent cementing actions existing in fresh flue-dust and which are made active by the presence of a small amount of a catalytic substance. Thus 0.25% of magnesium chloride mixed with fresh flue-dust and from 6 to 10% of water, pressed into briquettes, will create a strong reaction, noticeable by the considerable heat developed; the briquettes will be perfectly set and hard within a few hours. The process is very simple, an ordinary pug-mill being used in which to mix the material, which is subsequently pressed into briquettes in a toggle-press and then loaded on cars to allow them to set. Some flue-dust will react so strongly that a large amount of ore or coke breeze may be added to the briquettes; in these cases the flue-dust acts as a binder. The Schumacher process requires an inexpensive plant, and the cost of manufacturing is low. It is extensively used abroad and has replaced some of the other methods. The briquettes of all-agglomerated materials have given most satisfactory results abroad and highest returns and values to the blast-furnace operators.

Australian Gold Output

The decline in the gold output of Australia proceeds apace. It began in 1903-4, and has continued ever since. In 1903 the output amounted to 3,836,095 fine oz.; in 1904, to 3,742,549 oz.; in 1905, to 3,660,095 oz.; in 1906, to 3,444,606 oz.; in 1907, to 3,181,728 oz.; in 1908, to 3,074,315 oz.; in 1909, to 2,967,352 oz.; in 1910, to 2,717,715 oz.; and in 1911, to some 2,481,000 oz. The figures for 1911 are as yet only approximate, for the reason that the output for the last quarter in Tasmania has had to be estimated, and nothing but probabilities can be considered in regard to the returns from South Australia and the Northern Territory. If the estimate for 1911 be correct, and it assuredly is not far wrong, the decline amounts to 237,000 oz. in twelve months, 486,000 oz. in two years, 964,000 oz. in five years, and 1,355,000 oz. in eight years; in other words, the drop, when put on a percentage basis, amounts to very nearly 9% on the previous year's output, and to over 35% on the output for 1903. For the production to have declined more than one-third in the short space of eight years is very serious indeed, and perhaps not the least serious feature of it is that the decline is not confined to particular localities, but is general throughout the Commonwealth. Thus, turning to the figures for the various states, though Western Australia is once again enormously ahead of all its rivals, the decline even in this state has been steady, amounting to over 17% in three years. Victoria, whose total of 503,541 oz. compares very unfavorably with the 1,370,867 oz. of Western Australia, has suffered in the period a still more serious drop, equal to about 25%, and the condition of the industry in this state is beginning to give serious cause for anxiety. In Queensland, which holds the third place, with a return of 381,845 oz., the decline is practically in the same proportion as that of Western Australia. In New South Wales, whose output of 181,821 oz. entitles it to fourth place, the drop is one of nearly 20%. Tasmania has suffered more than

any of the others, a falling off amounting to 42%. The South Australian and Northern Territory totals are not available, but in all probability they also show declines. But, serious as is the drop shown in this three-year period, it is much heavier when the comparison is made, not with the figures of 1908, but with those for each state's best year of the past decade. Considering it in that light, Western Australia's decline amounts to nearly 34% in eight years, Victoria's to nearly 35% in five years, Queensland's to nearly 43% in eight years, New South Wales to about 34% in six years, and Tasmania's to more than 55% in six years. As for South Australia and the Northern Territory, the former's output dropped from 7111 oz. in 1909 to 6592 oz. in 1910, and the latter's from 5685 oz. in 1909 to 5111 oz. in 1910. The figures for 1911 will be available in the dim and distant future. It will not be far wrong, probably, to estimate about 11,000 oz. for the two. But it is not only absolutely that the Commonwealth figures of gold production have of recent years been so unsatisfactory. The unsatisfactoriness is even more marked by comparing the output to that of the world at large. In 1901, the proportion of the world's gold that came from the Commonwealth was no less than 26.26%. Since then, it has steadily declined till in 1910 (it need hardly be said that the world's returns for 1911 are not yet available), it stood at only 12.26% of the total. That is because, while the Commonwealth's output has declined from 3,297,228 oz. in 1901 to 2,717,715 oz. in 1910, the production of the rest of the world has increased during the same period from 9,260,000 oz. to 19,457,225 oz.; so that, while Australia has gone back materially, the output of the rest of the world has more than doubled. It would be agreeable to say that a better year is anticipated in 1912 than in 1911, but in point of fact everything seems to indicate a continuance of the decline. If there be any state that promises to do better this year than it did in the past year, it is Queensland. Except that state, it is doubtful if any will be able to show better figures for 1912. But there is no need for despondency. The country always turns away from mining in its days of general industrial, pastoral, and agricultural prosperity, such as it has been blessed with during the past few years; but when the present spell of prosperity has run its course, as it must inevitably do sooner or later, mining may be trusted to come to its own again, new enterprise bringing about new discoveries that will send the returns up with a run once more.—*Australian Mining Standard*.

THE Wandiligong Gold Dredging Co., at Bright, Victoria, during the half-year ended January 31, treated 263,253 cu. yd. of gravel, of which No. 2 plant treated 134,188 cu. yd. The gold won amounted to 1200 oz., valued at £4909, No. 1 contributing 652 oz. and No. 2 548 oz. To date the company has dredged 132 acres, of which 11½ was treated during the half-year under review, while the total yield to date amounts to 13,628½ oz., valued at £55,512. The total dividends paid amount to £15,210, or £2 10s. 8d. per share, of which 4s. per share was paid during the last half-year.

OF Western Australian gold received at the Perth branch of the Royal Mint during January, more than half (67,257 gross ounces) was supplied by Kalgoorlie, the next most productive field being the Mt. Margaret, which, however, furnished only 14,325 gross ounces, the average of the gold through the state being £3 9s. 1d. per ounce, as against £4 4s. 11.45d., which is the standard value of fine gold. The total production was 95,672.57 fine ounces.

INCREASING use of large shafts on the Rand has led to readjustment of underground transportation methods. The tendency now is to concentrate tramming on main haulage levels, handle the ore at main hoisting stations, and do the hoisting through large central shafts. Mules and ponies have never been used to any extent on the Rand for underground haulage, but are now being employed as a stop-gap until mechanical haulage can be installed.

Saving the Gold in Beach Sand

By A. H. HARRIS

Along the beaches of Oregon, sand containing gold and platinum is found. Many efforts have been made to save the fine gold, but failure has usually been the result. Recently, near Newport, a new style of concentrator has been constructed and is doing remarkable work. The machine handles 10 to 12 tons of sand per hour and is operated at a minimum expense. The whole scheme is simple and cheap. On the beach is a 'dead man' which is connected with the engine-house on the hill by two heavy steel cables. Attached to the cables is a bucket like that of a drag-line scraper. This is dragged along the beach and picks up about a ton of sand. It then runs up an incline of logs and dumps its load into a 'mill.' The sand falls on an incline, across which runs a stream of water. All the rocks, sticks, and clay are carried off this incline and dumped. The sand being lighter, is carried into troughs. The sand-laden stream then runs into the 'con-

nace showed that the matte produced was impure and that the slag carried too much copper. Further experiments demonstrated the easy feasibility of smelting the slag in conjunction with the recovery of the arsenic content. The matte obtained was free from arsenic and contained 21% Cu, while the slag held only 0.15% Cu, and the As recovery amounted to 65 per cent.

January Gold Output, Australasia

The following returns of gold yields from Australasian mines for January are given by the *Australian Mining Standard*:

Western Australia.—The output was 106,370 fine oz., valued at £451,830, as compared with 119,498 fine oz., valued at £507,595, for January 1911, the decline being 13,128 fine oz., valued at £55,765.

New South Wales.—The usual return furnished by the Under-Secretary for Mines shows that the yield recorded for January was 15,085 crude oz., equal to 12,906 fine oz., valued at £54,821, as compared with 16,516 crude oz., or

SCRAPER AT THE BEACH.

CONCENTRATOR.

centrator,' but before reaching it the stream is utilized to turn the 'platinum carpet.'

The concentrator, which is 6 ft. wide at its widest point, is floored first with heavy duck, on top of which are two layers of burlap, on which a quantity of quicksilver is sprinkled. This catches most of the gold; when the burlap becomes black, which is every two hours, it is taken off and washed in a tank containing chemical solution. After leaving the concentrator the stream falls on the platinum carpet. This is a strip of heavy carpet which is revolved slowly in the opposite direction to the flow of the water, and which picks up most of the platinum. It is washed in the same manner as the burlap from the concentrator. The stream then runs over an ordinary tailing screen and a little sand containing both gold and platinum is caught there. The tailing and the sand from the washing tank are re-concentrated by being run through a second and much smaller concentrator. Each 50 lb. of the last reduction represents a ton of the raw material. From this an amalgam is obtained and the gold and platinum retorted in the usual manner.

Electric Smelting of Copper Ores

Smelting experiments lately carried out in Germany with strongly arsenical sulphide copper ores in the electric furnace, fully described in *Metallurgie*, are of considerable interest to copper producers. The ore used contained 20.3% SiO₂, 10.1% Cu, 27.10% Fe, 9.45% Al₂O₃, 9.25% As, 0.48% Mn, 15% S. After being roasted from eight to nine hours, the ore had the following composition: 22.5% SiO₂, 10.5% Cu, 34.6% Fe, 11.5% Al₂O₃, traces of As, 0.5% Mn, 1.5% S. The carrying out of reaction smelting between ore and roasted material in an electric shaft fur-

13,397 fine oz., valued at £56,906, for the same month in 1911, showing a decrease of 491 fine oz., or £2085 in value.

Victoria.—The production of gold for January was 36,178 gross oz., or 33,787 fine oz., valued at \$143,519. Compared with the yield for January of last year, this was an increase of 2262 fine oz., valued at £9608.

New Zealand.—The January production of gold amounted to 35,875 gross oz., or 33,916.25 fine oz., valued at £144,067, as compared with 49,566 gross oz., or 46,086.5 fine oz., valued at £195,783 for the corresponding month last year, the decrease being 13,691 gross oz., or 12,175 fine oz., valued at £51,716. The silver produced in the Dominion during January 1912 amounted to 9464 oz., valued at £946, as against 114,845 oz., valued at £11,530 for January 1911, or a decrease of 105,381 oz. of a total value of £10,584.

The gold ore treated at Arltunga, Northern Territory, and at the Winnecke mill during November was as follows: Arltunga mill: 66 tons 15 cwt., which yielded 80 oz. 60 dwt. 5 gr., valued at £303 14s., the average extraction per ton being 1 oz. 4 dwt. 1 gr., or in money value equivalent to £4 10s. 11d. Winnecke mill: 28 tons 3 cwt., which yielded 33 oz. 8 dwt. 11 gr., valued at £132 10s. 4d., the average extraction per ton being 1 oz. 3 dwt. 17 gr., or in money value equivalent to £4 14s. 1d.

FEBRUARY PRODUCTION of the Nipissing Mining Co. amounted to 385,666 oz. of silver valued at \$226,419, which compares with 406,826 oz. in January and 407,114 oz. in December. During the month there was shipped ore valued at \$515,559. This figure was exceptionally large, owing to the low shipments of \$113,647 worth of ore in January.

GOLD has been found at Carrizal, about five miles from Putu, according to a report from Talea.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Transportation of Tailing Through Pipes

The Editor:

Sir—I have been much interested in several articles which have appeared in your journal concerning the transportation of battery pulp through iron pipes for great distances, and as data on this subject are rather scarce, probably the enclosed item, which was very kindly sent to me by T. J. Grier, superintendent of the Homestake Mining Co., at Lead, South Dakota, will prove of general interest to your readers.

cyanic acid, or in combination with the radicals with which the sulphur and chlorine have been combined. The precious metals having been precipitated as chlorides or sulphides, the superabundant liquor can be decanted off, and the potassium cyanide may be regenerated by decomposing the potassium sulphate formed by the action of the sulphuric acid from the solution. The decomposition of the potassium sulphate and the removal of the sulphuric acid may be readily accomplished by introducing lime into the solution and decanting off the precipitated gold and silver, the lime so added causing the decomposition of the potassium sulphate with the formation of insoluble calcium sulphate and simultaneous regeneration of potassium cyanide. In the operation of this process, it was claimed a regeneration of 90% of cyanide could be effected." The italics are mine. Two or three years ago I made some experiments upon cyanide regeneration with the use of sulphuric acid, and, as Mr. Nicholls states, practically rediscovered the essential features of the process accredited to Messrs. Anderson and Seanlan, as, at that time, I was unaware that any previous

HOMESTAKE MINING CO. DATA OF FLOW OF TAILING IN PIPE.

	Lead Sand Line.	Central City Tailing Line.	Lead Slime Line.
Diameter of pipe	12 in.	8 in.	12 in.
Thickness of pipe.....	9/16 in.	9/16 in.	9/16 in.
Average grade	Part at 5% Part at 2½%	1¾%	1½%
Bends in line	The pipes generally follow the contours of the hills; the sharpest curve is 22½°, a standard elbow for flanged C.I. pipe being used.		
Fineness of tailing	30% on 100-mesh 25% on 200-mesh 45% through 200-mesh	25% on 100-mesh 20% on 200-mesh 55% through 200-mesh	100% through 200-mesh
Water in pulp	70 to 75%	85 to 90%	65 to 70%
Solids per 24 hours.....	1950 tons	450 tons	1100 tons
Pipe runs	About ⅓ full	Full	
Wear of line	(It is customary to turn pipe through about 120° when bottom is worn thin; thus the pipe will be used until three lines of wear have been developed.)		
	On 5% grade, worn out in 2 years.	In use 8 yr. without turning. In use 5 yr. without turning.	
	On 2½% grade, worn from 9 to 10 yr.; most of line still in use after 11 yr., but badly worn.		
Remarks	Grade has been reduced to 2½% throughout, and new pipe 1 in. thick recently installed, for use in another month.		

The data are particularly interesting on account of the fact that the experience covers a period of eleven years.

Berkeley, California, March 20.

Cyanide Regeneration

The Editor:

Sir—In the article on ‘Cyanide Regeneration’ by George Nicholl in the *Mining and Scientific Press*, March 16, 1912, there are some statements, apparently quoted by Mr. Nicholl, which I believe are open to discussion.

Descriptive of the process patented by Isaac Anderson and Michael Seanlan, it is stated that, “This process is based upon the fact that when sulphuric acid is added to a cyanide solution of the precious metals in which sulphides and chlorides are present, the sulphuric acid so added will combine with the potassium of the potassium cyanide to decompose the double cyanides formed by the action of the potassium cyanide on the precious metals, and the metals freed from combination with the potassium cyanide will then combine the sulphur and chlorine present to form insoluble sulphides and chlorides, which will be precipitated, leaving the cyanogen in the liquid in the form of hydro-

experiments had been made along the same lines. Consequently I am quite interested in any articles upon the subject, and usually regard them rather critically. I realize, however, that the practical value of the process in comparison with processes of wider adaptability and greater proved utility, may not justify such a lengthy contribution. Certain conclusions which I based upon the experiments mentioned are somewhat at variance with statements made in the paragraph quoted. For instance, I do not believe that the presence of sulphides and chlorides is necessary to effect the precipitation of the heavy metals from a cyanide solution when sulphuric acid is added. If the sulphides and chlorides of the heavy metals are to be inferred, they would hardly remain as such in the cyanide solution, but would enter into chemical reaction therewith, possibly as follows:

$$2\text{CuCl} + 2\text{KCN} = \text{Cu}_2(\text{CN})_2 + 2\text{KCl}$$
$$\text{or, } 2\text{CuCl} + 4\text{KCN} = \text{K}_2\text{Cu}_2(\text{CN})_4 + 2\text{KCl}$$

In the presence of chlorides or sulphides of the alkali metals, the ultimate result, at least, of the reaction occurring upon the addition of sulphuric acid, I believe, would be the same as though they were not present, presumably

$$\text{K}_2\text{Cu}_2(\text{CN})_4 + \text{H}_2\text{SO}_4 = \text{K}_2\text{SO}_4 + \text{Cu}_2(\text{CN})_2 + 2\text{HCN}$$

This brings us to the statement regarding the precipitated

metals and their chemical form. The results of my experiments, the equation just cited, and other data led to the conclusion that they are cyanides; in the case of copper, probably $\text{Cu}_2(\text{CN})_2$. In support of this conclusion, I made a number of tests upon the precipitate by the process, treating a known quantity with acid in a stoppered flask. A tube leading from this flask conveyed the gases arising upon digesting the precipitate in acid, through a beaker of NaOH solution. Upon the conclusion of this treatment, titrations of the NaOH solution with silver nitrate showed sufficient cyanogen present, after making allowances for experimental error, to indicate that the reaction is as cited.

It further appeared that practically all of the cyanogen released remained in the solution in the form of hydrocyanic acid, rather than in any more stable form, as the odor of this acid was noted and, upon agitation or long standing, the available cyanogen content decreased, until, in time, it was practically nil, the decrease being in direct ratio to the amount of agitation or length of time the acidified solution stood exposed. Nor would the subsequent addition of acid to break up any cyanogen compounds which may have formed serve to restore any of the original strength of solution in available cyanogen. It therefore seemed fair to surmise that practically all of the released cyanogen remained in the solution in a volatile form.

* In my experiments it was noted that an almost complete removal of the gold and silver from the solution was effected with the precipitation of the baser metals, and assays of the precipitate showed the precious metals present therein in the quantities and proportions one would expect in that case. No attempt was made to isolate them in the form thrown down from the balance of the precipitate or to determine in what chemical form they are precipitated. As they are soluble in cyanide solution in a manner similar to the baser metals, it is not unreasonable to infer that the reactions which cause their precipitation and the resultant precipitate are analogous to those of the baser metals. In regard to the statement that the precious metals are precipitated as chlorides or sulphides, one would suspect a misquotation.

From the paragraph quoted, I gather that lime is added before the precipitate produced by the acid is removed. In that case, as my experiments indicated, the lime would neutralize the acid present and restore the hydrocyanic acid to a stable and available form, either as calcium cyanide, or, more probably, as potassium cyanide, by breaking up the potassium sulphate as described. This potassium cyanide, in turn, would re-dissolve the precipitate wholly or in part, dependent upon the length of time of contact. One would merely have moved in a circle, with the net result of the loss of some available cyanide, due to the escape of hydrocyanic acid during the process, and the loss of the acid and lime used. I found it wise to effect the removal of the precipitate as completely as possible before the treatment with lime. It is further stated that a "regeneration of 90% of cyanide could be effected." If the general equation of the reaction cited is correct, the possible theoretical saving, based upon the cyanogen in the solution, not that originally used, is not over 50%, unless the precipitate, which contains the remainder, is treated.

In conclusion, permit me to state that the deductions here given are based primarily upon my individual experiments, aided by a limited bibliography dealing in an unsatisfactory manner with the reactions occurring in cyanide solutions, and, furthermore, commercial practicability rather than the requirements of chemical research dictated the methods employed, consequently I may have overlooked some salient points which might be obvious to others better informed upon the subject. I am sending this contribution in the hope that, if such is the case, criticisms will be forthcoming. I might add that I was granted a patent upon the process as I worked it out, application for the same having been made before I learned of the experiments performed by Messrs. Anderson and Seanlan, consequently there may be some essential undetected differences in our methods.

R. P. WHELOCK.

Kingman, Arizona, March 22.

The Mine-Owners' Liability for Accidents

The Editor:

Sir—I find in your issue of March 9 a thought-inspiring article from the pen of F. J. Martin, of Angels Camp, in relation to 'Employers Liability and Accident Insurance,' and, if you can spare the space in your columns, I should like to discuss some aspects of the Roseberry Liability and Compensation Law as they relate to the hazardous occupation of mining. This industry stands by itself, and its importance to the state is, as Mr. Martin points out, very great, and deserving of careful consideration. But it will be impossible to treat a subject of such surpassing importance within the limits of a single article, and so, with your consent, I shall be glad of an opportunity so far to trespass upon the hospitality of your columns as to furnish a series of short letters upon the Roseberry law, with especial reference to the mining interests of California. It will be a necessary prerequisite for understanding what is to follow, to lay a foundation of succinct statement as to what the Roseberry law is and what it undertakes to do, as well as to set forth the fundamental reasons why it undertakes to do the things that it does.

By the way, mining divides with seafaring the honor of furnishing the impulse which sent the world toward the compensation system of caring for industrial accidents. It was early noted on the continent of Europe, and in Great Britain, that these two industries contributed very largely to the pauperism of crippled men and their dependent women and children, and, more than a century ago, parliaments and imperial councils began to say to employers engaged in these occupations: "See here, you are hurting a great many men and throwing very heavy burdens upon the poor rates. You must take care of your own killed and wounded and those dependent upon them, and not leave them for others to care for," and they did it, at least partly. If they did nothing else, ship-owners and mining companies established hospitals and relief funds, mainly paid for at first by deductions from the wages of their workers, but added to more and more by the owners as the years went by until public and official sentiment settled down to the conviction that each industry should be made to care for its own killed and wounded and those dependent upon them; the corner-stone of the compensation theory of dealing with industrial accidents.

First enunciated with relation to these two, perhaps the most hazardous of all industries except that of wrecking old buildings, the principle was applied to the railroads when they came into being, to mill and factory workers when the high-pressure engine had revolutionized industry, and so on, extending from industry to industry in the order of their respective degrees of hazard, until, in all Europe and Christendom generally, outside the United States, practically all industries and occupations came under the 'compensation' theory of caring for industrial accidents. So it may be perceived, on investigation, that this Roseberry law, which at first seemed so new a thing to be hurled unannounced upon the industries of the state, really is not a new thing at all, but only new to those of us who did not happen to know about it. It was long, very long on the way, and very much more tardy in America than is creditable to us Americans.

Now the Roseberry Liability and Compensation Act is a two-part act. Part I consists of the first two sections and has to do with liability in damages for injuries inflicted as a result of negligence. Part II has to do with compensation for accidents without regard to negligence and requires twenty-nine sections to set the matter out *in extenso*. Every employer in California is doing business under one or other of these two laws, for they are in fact two separate and distinct laws, although grouped together in one legislative act. Each such employer must determine for himself which of these two masters he will serve. He cannot well serve both, and he cannot choose to serve neither and do business in California. It is 'up to him' to say which. If any employer does nothing about it, he is under the law of liability in damages for injuries inflicted be-

cause of somebody's carelessness, or, as it is generally termed, negligence, and will so remain until he does do something about it. If, after investigation, an employer concludes that it will be better, on the whole, to pass from under the law of 'negligence' to the law of 'compensation', all that he has to do is to notify the Industrial Accident Board, Pine and Sansome streets, San Francisco, to that effect, and that Board will place him under compensation in five minutes, and there he will have to remain for one year.

A great deal of misapprehension has existed in the public mind on this point, more especially among farmers, perhaps, but too prevalently among other employers and employees generally throughout the state. They have supposed that the Roseberry law consisted wholly of its 'compensation' provisions, and that the amendment to the state constitution, adopted October 10, 1911, giving the legislature power to make such a law compulsory, did in fact, by virtue of its adoption, make the compensation provisions of that law compulsory upon all. Such is not the case. That amendment only gave the legislature power to compel, but it has not yet exercised that power and ought not to exercise it until the people of the state have become thoroughly familiar with the law and its purposes, and also not until the statute has been perfected in numerous incidental but important details and in the light of actual experience in its practical application to human affairs. The compensation provisions of the Roseberry law are still elective, and whoever has not elected to do business under them is not under them, and they are, to him, as though they did not exist. This is not quite true of the 'Liability in Damages' provisions. They are compulsory upon all who do not elect the compensation provisions, and they were very greatly changed by the Roseberry act; but of that more in a later installment of this series.

There is a sense of humiliation in the thought that great, progressive, free America should be thirty years behind Europe in grappling with this, perhaps the greatest reform movement in economic history since feudalism gave place to free industry, and yet the reason why is not far to seek. With something like a million persons a year pouring into our land from over seas we have, so to speak, had 'men to burn,' whereas Europe, feeling the drain of its labor to America, has had to conserve its working population. It was the great Bismarck who laid down and made effective the profound truth that every able worker is a national asset and as necessary to be taken care of, if the Fatherland would grow rich, as that horses and mules, cattle and hogs, be taken care of; and so he established a universal and compulsory insurance system that virtually provides care for every German toiler from the cradle to the grave. But if in America a workman was killed there was always another to step in and take his place, and so why bother to take care of men any more than of our (supposedly) inexhaustible acres of soil and timber, coal and iron? Rounded up by Roosevelt and his conservation cry, we have discovered that nothing is inexhaustible, neither acres, nor soil, nor timber, nor coal, nor men, and conservation becomes the watchword all along the line, from broad acres to toiling men and women. This, then, is the reason why the compensation issue is upon us, and why and how it came to be a 'burning issue' of our time.

Slime Filters in New South Wales

The Editor:

Sir—In Alfred James' able 'Review of the Cyanide Progress for 1911', he states that the Ridgway slime filter has ousted a "grouped frame filter of well known type in New South Wales." He is certainly misinformed. There are only two vacuum slime-filter plants at work in New South Wales at the present time. One is at the Occidental mine, Cobar, being the first Moore filter plant erected in Australia, and still working most successfully; and one No. 2 type Ridgway is working on some residues at the Mitchell's Creek

mine, Wellington. The only other vacuum filter plant that was erected in this state was a Wilfley drum, at the Myall's and Peak Hill mine, but was found unsuitable. The largest gold mine in this state, the Mount Boppy, is now erecting a new slime plant and adopting the Moore filter.

Treatment of Matte From Mill Clean-Up

The Editor.

Sir—I have read with considerable interest the article by M. W. von Bernewitz in the *Mining and Scientific Press* of March 2. I also tried the process of treating matte by reducing it with potassium cyanide soon after reading A. E. Drucker's article, but I did not like the process, as it yielded a thick pasty slag, rich in gold and silver. I am operating a cyanide plant and treating about 80 tons per day of mill tailing and canvas sweeps. I dip my zinc-shavings in a solution of lead acetate when charging them into the precipitating-boxes, hence my melt contains quite a quantity of lead in addition to the usual matte. My process of treatment is as follows: I clean up twice a month and the acid-treated precipitate is melted in two furnaces, using No. 25 plumbago crucibles. The result is about 15 lb. of lead, and matte, in addition to the precious metals. This I oxidize and refine in about three hours time, by using a modification of what Mr. von Bernewitz terms bessemerizing; but which I think might more properly be called crucible cupellation.

I have a $\frac{3}{8}$ -in. air-line from the air-compressor, ending with a valve to which is attached about 6 ft. of $\frac{1}{2}$ -in. rubber hose, and 4 ft. of $\frac{1}{4}$ -in. pipe for a nozzle. The pipe-line runs along the roof of the melting-room, so that the hose and nozzle come down from above, and are made adjustable by means of a rope that is fastened to the air hose and to one of the rafters. The melting pot is covered with a plumbago cover, having a small slot in one side to admit the end of the pipe, which is adjusted so as to enter the melting pot at an angle and is kept about 4 in. above the surface of the melt. I use a large quantity of air under about 10 lb. pressure, and add borax and silica to absorb part of the metallic oxides and protect the pot. The melt gives off dense fumes of zinc, lead, and sulphur, so that it is impossible to remain in the room even with the windows open in addition to top ventilation of the building. I shut the air off and skim off the slag when it gets thick enough to interfere with the cupellation of the base metals. When the matte and lead are oxidized the dense fumes cease and the melt is poured. This gives a bar about 550 fine in gold and 250 in silver, the remaining base being chiefly copper. This can also be removed by long-continued blowing and fluxing, but is unprofitable.

I once made a lot of clay pipes about 3 ft. long and tried refining by Rose's method of blowing air into the metal, but it bubbles violently and spatters metal all over the room if a strong blast is used, while if only a small quantity of air is admitted it works much slower than when using a strong blast on the surface of the melt. When refining I keep the furnace covered, with the exception of a small opening to admit the $\frac{1}{4}$ -in. pipe into the furnace, and through the hole in the crucible cover, and maintain a high temperature, as the matte will not burn at a low one.

WILTER E. DARROW.

Amador City, California, March 8.

COPPER PRODUCTION in the Transvaal for January consisted of concentrate of the value of £4453. In the same month 234 tons of tin concentrate was shipped, valued at £26,682.

THE Great Cobar G. M. Co. (New South Wales) metal output from January 3 to 31 was: Copper produced at Cobar, 42 tons, containing by estimation 2250 oz. gold and 10,751 oz. silver.

Special Correspondence

RHODESIA

DEPRESSION IN SHARES.—CAM & MOTOR CO. IN GOOD CONDITION.—DIVIDEND NOTES.—GEOLOGICAL SURVEY TO PUBLISH REPORTS.

Rhodesian stocks in common with South African shares generally have been much depressed. The Amalgamated Properties of Rhodesia affair has exerted a depressing influence on the market, and it is an open secret that at several of the leading mines of Southern Rhodesia the position at present is far from satisfactory. At the Eldorado, for instance, development of late has been discouraging and it is freely rumored that the pay-shoot is contracting as work proceeds in depth. Report has it too that in the lowest levels of the Globe & Phoenix conditions are unsatisfactory. Add to this the fact that the Giant Reef has not yet been re-discovered. These are the most profitable three mining projects in Rhodesia, and that Rhodesian shares generally should be depressed because of unsatisfactory developments in their lowest workings is not to be wondered at. Then again, the Surprise mine, near Selukwe, for which such good things were anticipated is virtually on its last legs and will probably be operated on a tributing basis by a small syndicate of working owners. Numerous properties in the Salisbury area have also been closed

MILL AT GIANT MINE.

down, and in a few instances have been forced into liquidation.

The brightest spot in the mining industry of Southern Rhodesia today is undoubtedly Gatooma, where the Cam & Motor Co. is opening up a huge body of ore of more than average value. Development in depth is satisfactory, and in the opinion of many competent judges the Cam & Motor is destined to become the second mine of the country and will rank next to the Shamva mine at Abercorn in point of size, production, and profit. At the end of September the ore reserve in the Cam & Motor was estimated to amount to 700,000 tons, of an average assay value of 47s. 2d. per ton, the total gross value thus amounting to £1,653,000. During the past few months this tonnage has been largely increased and today there is probably over a million tons of a gold content averaging close to 11 dwt. per ton exposed in the mines. As to the Shamva, the last statement regarding development placed the reserve at 1,555,000 tons of 4.77 dwt., 'reduced value.' Under C. W. Terry's management development work is being rushed. H. A. Piper, consulting engineer for the company, recently arrived in Bulawayo from England, and his return to Rhodesia is expected to indicate increased activity. An encouraging feature in connection with the Rhodesian mining industry is the increase in dividends. Not only was the 1911 gold output a record production, but, what is of greater importance from the point of view of investors, the profits distributed last year were greater than in any previous year. The Globe & Phoenix mine paid out 160%

or £320,000, as compared with 125% or £250,000 in 1910. The Giant Mines distributed 40%, as compared with 15% in the previous year. The Lonely Reef company paid its first dividend of 10% on a capital of £271,000 and the Selukwe Columbia 10% on £110,000. The Eldorado Basket mine maintained a distribution of 30% or £90,000, and the Rhodesian Exploration & Development Co. declared 10% or £150,749, the same as the 1910 distribution. The total for all companies has been given at £933,422, which compares with £883,829 in 1910, £421,950 in 1909, and £197,837 in 1908. Mention may also be made of the fact that the Consolidated Gold Fields, which has large Rhodesian interests, paid out £600,000, equal to a dividend of 30%, for last year.

Much satisfaction is expressed at the announcement by H. B. Maufe, director of the Geological Survey of Southern Rhodesia, that, in the future, reports will be regularly published and that special monographs relating to vital economic problems will be issued. It is now 15 months or more since Mr. Maufe arrived in Rhodesia to take over his important duties, yet up to the present the Government has not seen fit to issue any official statement. Mr. Maufe has a vast field for his labors in Rhodesia, and he is understood to have already obtained much valuable data. It has thus been very naturally felt that the Chartered company was guilty of a distinct error in keeping the results of the director's work a secret.

ELY, NEVADA

STEPTOE PLANT SECURES PERMANENT WATER-SUPPLY.—

GIROUX ACTIVITIES.—BOSTON ELY TO SEEK SECONDARY ENRICHMENT.—ELY CENTRAL MAY RESUME.

Weather conditions for the entire winter have been quite favorable for mining and milling in the Ely district. During the earlier months of the winter there was a scarcity of water for milling at the Steptoe plant, but that has now been overcome by a series of settling-tanks and the pumping back of the water which had passed over the tables. About 4500 gal. of water per minute is now being pumped back and used again, giving a guarantee of an ample water-supply for the present capacity of the plant. The plant is now running at about its full capacity, treating 10,000 tons of sulphide ore per day. The ore comes from the Copper pit, the new Liberty pit, and the Veteran mines of the Nevada Consolidated. The ores from the pits average about 2%, while that from the Veteran mine averages about 3½% copper. All of the ores average about 20c. gold per ton.

The Giroux company, which has been so long in the preparatory stage, will enter the shipping list about May 1, under a contract with the Steptoe Valley M. & M. Co. for treating 1000 tons of ore per day. The Giroux ore averages a little higher in copper content than that of the Nevada Consolidated, and contains about 60c. gold per ton. It is stated that the Giroux company secured a favorable contract for treating its ore, and at the present price of copper will be able to net about \$600,000 per year from ore shipment. The Morris shaft on the sulphide zone has been well equipped for handling the output, and all the old workings in that part of the property are being cleaned out and the mines put in shape for heavy production. Development in the Alpha mine of the company's property has been practically abandoned for the present. The Giroux shaft, in which a fire occurred August last, has been retimbered and put in shape to the 1200-ft. level, and the pumps are in operation raising the water from below that level. The water is being lowered at the rate of three inches per day, and at this rate it will be nearly two years before the 1400-ft. level will be reached, barring accidents, after which work will be resumed on that level and the Giroux shaft sunk to a depth of 1800 ft. The tremendous inflow of water is favorably regarded by the management as a guarantee of sufficient water for milling purposes when the company is ready for the erection of its plant and smelter. The Boston Ely company soon will have diamond core-drills in operation on the 1245-ft. level of its

property, to seek the secondary enrichment believed to exist on account of the leaching shown in the big vein above the 1245-ft. level. The management has proved a large amount of low-grade ore, but so far little of it is of a commercial grade. The Ely Consolidated company has decided to continue its Zaek shaft on down from the 600-ft. level for a distance of at least 200 ft. It has developed a large amount of good ore above the 600-ft. level, but as the veins still show much leaching, it is considered advisable to go to greater depth with the shaft. A 600-gal. pump will be placed on the 600-ft. level. The shaft will be followed down by Cameron sinkers as it attains depth. R. T. Pierce, consulting engineer for the reorganization committee of the Ely Central company, has been spending a few days in the district, looking over the company's property. It is expected that the company will soon resume operation.

LONDON

CARN BREA & TINCROFT HAS ENCOURAGING REPORT.—MY-SORE STILL LEADING KOLAR DISTRICT PROPERTIES.—COPPER COMPANY NOTES.

Carn Brea & Tineroft is certainly one of the most cheerful spots in Cornwall at present. The report for the six months ended December 31 shows clearly that at last a 'live' man is in control of operations, and that the whole affair is being regarded and conducted as a business proposition. E. S. King's speech to the shareholders was a distinct change from the type of remarks one usually gets from a Cornish mine manager, for he not only exhaustively dealt with matters which closely concerned the shareholders, but touched on such subjects as Cornish metallurgy, working costs, and his new setting system, all of which are interesting to the County as a whole. This policy of speaking frankly on such matters must surely be regarded as a step in the right direction, and will, I hope, do much to break down the reticence of the average manager and lead him to consider the value of conferences on subjects of mutual interest. During the six months, 41,670 tons of ore was crushed, with a production of 440 tons black tin, or an average recovery of 23.64 lb. per ton. The total receipts amounted to £51,885, or 24s. 10d. per ton milled, while the working cost, exclusive of 5.29d. per ton for capital expenditure, was £47,505, or 22s. 4d. per ton, showing thus a profit of 2s. 6d. per ton, or £5298 for the six months. Another feature of the report is that an intelligible analysis of working costs is given, and I hope the other large mines will follow suit. Below are given the more important figures:

	— Per ton milled. —			
	s.	d.	s.	d.
Mining:				
Breaking ore	6	11.59		
Trucking and raising ore.....	1	8.59		
	—	—	8	8.18
Treatment:				
Rock breaking	0	5.02		
Ore transport	0	8.17		
Milling	2	0.18		
Concentrating	1	4.04		
Roasting	0	3.11		
Dressing	1	3.53		
Fine grinding concentrate.....	0	1.69		
Magnetic separator	0	1.91		
Disposal of residue.....	0	0.62		
	—	—	6	4.27
Re-treatment			0	6.47
Pumping			2	7.95
General charges			1	4.08
Development			1	10.50
Royalties			0	10.86
	—	—	22	4.31

The Mysore Gold M. Co. property continues to hold its position as premier mine of the Kolar district of India and the developments still disclose large bodies of ore. The results for 1911 show that the tonnage crushed and the

gold extracted both presented record figures. On the other hand, the dividend was less than during the years 1903 to 1907. This fact is explained partly by the lower grade of the ore and partly by the charging of all costs to revenue instead of issuing new shares to meet extraordinary expenditure. The ore crushed during the year totalled 291,477 short tons, and by amalgamation and cyanidation, chiefly the former, gold worth £896,651 was recovered. The working cost was £335,341, royalty £53,201, income tax £26,318, depreciation £13,173, allocation to reserve fund, and £44,344 expended on new plant. The dividend absorbed £366,000, being at the rate of 120%. During the year 31,766 ft. of development work was done, and on December 31, the reserve was calculated at 1,300,369 tons, being an increase of 67,862 tons during the year. The development in depth is extremely satisfactory at many points. Edgar's shaft has been put in commission, and is an important factor in decreasing the cost. It is intended to commence the sinking of a similar shaft in MacTaggart's section. Additional ground has been acquired to the west of the property on the dip of the lode, so as to protect the deep levels.

For several years the Bwana M'Kubwa Copper M. Co. has been searching for a method of treating its carbonate ore. This mine is situated in northwestern Rhodesia, not quite so far north as the more celebrated Katanga deposits. The company now announces that it is about to erect a "plant on the spot to treat 75 tons per day." With the usual contempt for the public shown by Rhodesian companies, no information is given as to the nature of the plant or the process, and specific questions on this point put by me at the offices of the company remain unanswered. I asked whether it was a smelter that was to be erected, or whether a wet method was proposed; as a further alternative I suggested that perhaps the plant was a concentrator and that the concentrate would be shipped elsewhere for treatment. In spite of these leading questions, the reply was invariably that the official circular contained the whole of the available information, and that the office could not commit itself as to the nature of the plant.

Three months ago I recorded that the general meeting of the Famatina Development Corporation, working the copper mine at Chilecito, Argentine Republic, was adjourned for three months in order that R. F. Bury, the director, who was then visiting the mine, should be able to address the shareholders, and also that the board's recommendations as to the future policy should be discussed. The company has now published the new plan for the re-arrangement of capital, whereby the income bonds, profit-sharing bonds, and selling commission are extinguished. The reconstructed company will have a capital of £400,000 in 5s. shares and £200,000 6% debentures. Ordinary shareholders will receive one new share in place of each old £1 share, the total being 563,074. Holders of profit-sharing bonds will receive one new share for every three bonds, the total being 170,338. Holders of income bonds will receive 257,200 shares, and the International Copper Co. will receive 60,000 shares as part purchase of the selling contract. The debentures will be allotted as follows: £156,000 to be exchanged for the present 10% debentures, and £24,000 allotted to the International Copper Co. as the balance of the purchase price, £20,000 remaining in reserve. The report of Hooper, Speak & Co. on the progress at the mine and smelter shows that transport difficulties have continued to seriously interfere with mining and metallurgical operations during the year, and that there are severe losses of the copper and silver during smelting owing to their escape as dust. Walter G. Perkins, late of Steptoe, has recently left for the mine in order to improve the smelting operations. The negotiations of Mr. Bury on the spot have resulted in many reforms, and the outlook is now much more favorable than before.

I have referred before to the absorption of the Einasleigh Copper Mining Co. by the Chillagoe company, in North Queensland. It is now announced that the latter company is about to call up the shilling liability on the 1,160,000 shares, in order to provide additional capital for various purposes. In the first place £10,000 has to be paid as part

purchase price of the Einasleigh property, and further expenditure will be required in connection with the development of that mine; secondly, the damage done by fire to the Chillagoe smelting plant has to be made good; and, thirdly, money is being spent in developing the Mount Mulligan coalfield and providing a railway thither.

The laying of the track of the railway between Arica on the Chilean coast and La Paz in Bolivia was completed on March 4 and the line should be ready for traffic in six months time. The railway is 275 miles long and in passing over the Andes rises to an elevation of 14,000 ft. above the sea. The new line will be of great benefit to the tin industry in the neighborhood of La Paz and Oruro, as it will afford a short cut to the seaboard, and avoid the roundabout and expensive routes to Mollendo in Peru and Antofagasta in Chile.

It is announced that the Aroa Copper mine in Venezuela has been successfully reopened, and that the syndicate having the matter in hand is intending to ask for public subscriptions in order to provide the necessary capital for extending the scale of operations. This mine was worked from 1866 to 1894 by the Quebrada company, one of the Matheson, or Rio Tinto and Mountain Copper group, but in 1894 the workings collapsed and the property was abandoned.

The commercial application of nitrogeneous compounds produced by fixation of the nitrogen of the air is proceeding rapidly. Calcium cyanamide or 'nitrolim' is proving acceptable as a fertilizer, and the Alby Carbide company is consequently greatly extending its factory at Odda on the Hardanger fjord, Norway. Hitherto, this company has been producing calcium carbide chiefly for acetylene manufacture and its present capacity is about 32,000 tons per annum. The works are to be extended to a capacity of 80,000 tons. The process used for making cyanamide from carbide was invented by Frank and Caro, and consists of heating the carbide at high temperatures with nitrogen that has been obtained by the fractional distillation of liquid air.

BOSTON

COPPER SITUATION PROMISING.—NEW ENGLAND SEEKS PLACE ON ANACONDA DIRECTORATE.—LAWTON CONSPICUOUS BY QUIETUDE.—LAKE AND OLD DOMINION NOTES.

The copper-metal situation appears to be about all that could be reasonably expected from it from the standpoint of the producers. Despite the talk of the disappointing report by the Copper Producers' Association covering February there has since been an advance of nearly one cent per pound in price. Sales at this writing have been made both in this country and abroad at 15½¢. The talk of 16¢ copper is now stronger than was that for 15¢ copper. When copper was coquetting around 14¢, it was staple talk from the producing interests that they were concerned lest the price should run away with the market. That sort of talk was received with mental reservation. Many people have wondered why the copper producers were lying awake nights because of the menace of 16¢ copper or better, but such was the line of talk given out by these gentlemen, and it evidently served the purpose for which it was intended.

While the Amalgamated-Anaconda situation is strong the status of the Butte independent companies is equally strong, and this also attracts attention. Outside of Anaconda there are eight active producing independent companies at Butte: North Butte, East Butte, Butte Central, Butte & Superior, Tuolumne, Davis-Daly, Butte-Alex. Scott, and Elm Orlu. Raven, Butte-Ballaklava, and one or two others are active in development.

North Butte has increased its quarterly dividend rate from 30 to 40 cents per share. An attorney here by the name of Barry has been advertising to get correspondence from North Butte stockholders for the purpose of starting a crusade to get strong New England representation on the North Butte board. The market course of North Butte has not commended itself to Boston for several years, and there

is a desire to place a New England balance wheel on the company. This desire is largely the same as was the one in the Davis-Daly case when Heinze was running that company to suit himself. The New England interests, long-suffering to a fault, put up with Heinze's fantastic administration until they could stand it no longer. Then they made a demand for a larger hand in its management, and after being 'stalled' by Heinze for two or three years they finally got what they asked for, including Heinze's abdication. New England interests believe that the control of North Butte lies in the hands of the public—the New England public—and does not reside with the interest that own the largest blocks of stock. They believe that North Butte, like Davis-Daly, has been exploited to some extent for the benefit of other mining properties. The attorney is gathering proxies made out to himself, and the chances are that a lively fight will be started. The New England people plan to send an engineer to make an examination of the North Butte mines. It has been a complaint on the Street that the publicity by North Butte has been tainted. The mining share market will be all the better for the clearing of the atmosphere which the New England investigation of North Butte promises.

The long lapses into silence of Thomas W. Lawson in market affairs are a mystery to the Street. For two or three years Lawson has largely abstained from his customary methods of blatant self-advertising. Can it be that he finds silence to be golden, whereas speech was only silver—or copper? Nobody believes that Lawson has permanently retired or that he has given up the fight—for his own pocket. He has lived a strenuous life, and as he approaches 60 years of age probably feels like slowing down a bit. It is difficult to account for Lawson's silence on any score—save age and natural desire for relaxation. The latest bit of advertising given him is the suggestion that he run as a candidate to the Chicago convention as a Roosevelt man. Politics and finance make strange bedfellows. Lawson, however, has been more consistent as an ardent admirer and supporter of Roosevelt than in any other way which can be recalled at the moment. It would be appropriate for him to go to Chicago as a booster for Roosevelt, and market interests here would be glad to see them doing battle side by side in a convention. It would be worth going miles to see.

Ordinarily, blessings brighten as they take their flight, but with Lake Copper the glow increases as the time approaches for regular shipments. Lake is already selling at double its low selling price of last year and it is steadily moved upward in a favorable copper market. The first week's mill run shows a recovery of 23.62 lb. copper per ton. This mill-run comes from the stock pile, and the management says does not represent the average of the Lake mine. The present management is handling Lake, both as a mine and on the market in a radically different manner from the old regime, when the stock was inflated to \$94 per share. Nobody expects to see the stock sky-rocketing again, now that the control has changed, but Lake is regarded as a rich and promising property, though not yet out of the prospect stage, and its career will be watched with great interest. It will begin its regular production period in the early summer.

Now that the sceptre has passed from Harry F. Fay to the St. Mary's Mineral Land Co., a company with a history coincident with that of the Lake district, the public will watch with interest the course of Mayflower. Mr. Fay, as president, mustered up the strongest showing of any faction at the annual meeting, receiving proxies from over 75% of the individual stockholders and represented over 40% of the stock. But with St. Mary's and an allied Stock Exchange interest against him he was outvoted and deposed. The statement was made that with the passing of Fay the spectacular career of Mayflower would come to an end. So far as the tape tells the story, this prediction has come true since the meeting. Mayflower has scarcely held its own in the quotations and has yielded to other stocks in activity, whereas a few weeks ago it held the centre of the stage. However, it is assumed that the program of drilling carried on by Mr. Fay with such brilliant results in the last few

months is to be continued, and it is said that Mayflower and Old Colony, which may be physically classed as one property, though they are separate and distinct companies, will have four drills operating at an early day. The St. Mary's company is a large factor in the Lake mining situation, but its action in taking over the management of a mine is a new departure in its history and will be watched with interest and suspended judgment.

Renewed buying of Old Dominion trust receipts has given rise to some interesting comment. These trust receipts represent a beneficiary interest in the litigation for the recovery of something over \$2,000,000 for the Old Dominion company of New Jersey from A. S. Bigelow. This case is now pending before the United States Supreme Court. The Massachusetts Supreme Court decided against Bigelow, and the case is now before the court of last resort for review and final action. But the comment is to the effect that the defendant, Mr. Bigelow, in anticipation of an adverse decision is 'hedging' by accumulating the trust receipts. He formerly was considered a great obstructionist in the Lake district, but has been apparently quiescent there for several years. His mantle seems to have fallen upon Godfrey M. Hyams, who is now opposing Calumet & Hecla's plan to enlarge the milling facilities for Isle Royale.

PORCUPINE

MILD WEATHER PROMOTES DEVELOPMENT.—NORTH DOME TO ENLARGE SHAFTS.—GENERAL NOTES.

The mild weather has enlivened the district. The properties in northeast Tisdale are, on the whole, proceeding systematically with development, though the management of the Dobie has decided to discontinue operations in North Tisdale for the present. The Hughes property, under the management of Mowry Bates, is continuing development, sinking the shaft to the 100-ft level, and diamond-drilling to seek the orebody underground. The Mulholland, in charge of David Allen, is sinking the shaft to the 200-ft. level, from its present depth of 125 ft. About 350 ft. of driving has been done on the 90-ft. level.

The Crown Chartered Co., under the management of C. W. Dike, is sinking from the 150 to the 200-ft. level, and proceeding with the blocking out of the orebodies at each level. New boilers are being placed, and a seven-drill Rand compressor is being erected. The Scottish Ontario is still closed down, pending the return of Peter McHaren. The West Dome, managed by J. B. Cleveland, is cross-cutting at the 100-ft. level in No. 1 and 3 shafts to find orebodies.

Two diamond-drill holes have been put in 1100 ft. apart on the Dome Extension property, showing good ore along the contact between quartz porphyry and slate. A third hole is being put in midway between these to cut the same contact at a vertical depth of about 450 ft. The cross-cut on the 200-ft. level in No. 1 shaft is being pushed in a northerly direction toward the main Dome vein, the face of the cross-cut showing some good ore. The North Dome, in charge of Bert Wolfram, is cross-cutting and driving in ore in No. 1 shaft. The management plans to enlarge No. 1 shaft, and possibly No. 2 shaft, and then sink to the 100-ft. level. The northeast drift in No. 1 shaft went through 35 ft. of quartz showing free gold.

The Three Nations, under management of J. N. Agrignon, has finished sinking the shaft to a depth of 100 ft., and after cutting out a station and sinking 10 ft. for a sump, will cross-cut to intersect the main vein. The vein dipped out of the shaft at a depth of 42 ft. to the south. From 70 to 85 ft. in depth the shaft cut several quartz stringers, varying two inches to two feet in width, showing free gold. The LaPaline, Poreupine, Xiora, and Poreupine Tisdale are not operating at present, pending the erection of machinery. The Bewick-Moreing interests have discontinued underground work at No. 1 camp, and will continue assessment work on several of their claims. Owing to the cessation of the power from Sandy Falls, the McIntyre management has ordered a plant for operating the mill, among other things a 40-hp. boiler and a high-speed engine. The company will operate the mill by steam in the future.

REPUBLIC, WASHINGTON

FERRY COUNTY AGAINST TARIFF REDUCTION.—DISTRICT PRODUCTION FOR JANUARY AND FEBRUARY, 7222 TONS.—DEVELOPMENT NOTES.

The Northwestern Mining Convention, held at Spokane in February, struck the keynote of interest in Ferry county in its strong opposition to a reduction in the lead tariff, as proposed in the Underwood bill in Congress; in its condemnation of the Government's restrictions on the utilization of water-power sites, and of the Roosevelt, Pinehot, and Taft policies of Federal conservation of public lands as discouraging national development. As to the lead tariff, while it does not affect the Republic district, it assuredly does every other district in Ferry county.

During the months of January and February the ore shipments from the mines of Republic district amounted to 7222 tons, as follows: From the Republic Mines Corporation, 5195 tons; Knob Hill company, 1080 tons; San Poil Consolidated, 604 tons; Insurgent Leasing Co., 252 tons; and Emperor-Quilp company, 91 tons. The Hope company has straightened the shaft of the Blacktail mine, and equipped it with hoisting machinery. The company is now planning for more extensive development. Since the main shaft of the Surprise mine was completed to the 600-ft. level, a saving of expense has been effected, by direct hoisting through the Quilp shaft. The Surprise mine is now sending out to the smelters five earloads of ore every other day from above the 500-ft. level and a carload daily from below it.

The San Poil Consolidated company expects to have its mill complete and in operation not later than May 1. The Knob Hill company has intersected the northerly continuation of the Pearl-Surprise vein in the north drift on the No. 4 level of the Knob Hill mine, but found ore of only very low grade. The company lately has been shipping from three to four earloads of ore per week, of an average value of about \$100 per ton. The Quilp G. M. Co. has paid its fifth dividend of one cent per share on its capital stock, making a total of \$67,500 to date. W. D. Timm, superintendent for the Republic Gold Coin M. Co., has worked alone on its property, the Morning Glory mine, during the winter, following a very narrow streak of ore, which assays \$5000 to \$30,000 per ton, and another orebody which assays about \$1500 per ton. About 20 tons have accumulated and will soon be shipped to the smelter. W. J. Delbridge and associates have taken a lease and bond on the Knob Hill Extension claim, the bond calling for \$20,000. The San Poil Consolidated company is putting the San Poil mine in shape for stoping ore, to supply its mill, and is shipping only such ore as is necessarily broken for that purpose—about ten tons per day. The Belcher mine is employing about 22 men and sending from 50 to 60 tons of ore per day to the smelters. The Phoenix G. M. & M. Co., operating in the Curlew district, 20 miles north from Republic, owns three separate groups of claims, but is now confining its attention to the Panama group, on which it is driving a 1500-ft. adit. The old Republic mine, which was bought in by Ferry county at a tax sale, about three years ago, was afterward leased and bonded to the New Republic company for two years, the purchase price having been \$40,000, payable in installments. The Rathfon Reduction Co. succeeded the New Republic company and has had the lease and bond extended for another two years. The Rathfon Reduction Co. has worked over the tailing from the mill formerly operated by the Republic Power & Cyaniding Co. on the ore from the Republic mine and is now preparing to put in fine-grinding machinery and treat the ore from the mine. The tailing treatment is said to have yielded a fair profit, but nothing definite can be learned in relation to the milling. Cyrus W. Bradley, president of the Meteor M. Co., is directing work at the Meteor mine, in the Moses district. The ore assays as high as \$300 per ton, mostly gold. C. L. Fish & Co. have purchased a mill-site on Hall creek, and will put up a mill for the New York and Montana mines.

General Mining News

ALASKA

THE KOYUKUK

News despatches report a rush from the Tanana and other districts to the Koyukuk. Hastings & Sebrey, who discovered rich ore last summer, abandoned their prospect shaft, which caved in, and sank a working shaft 200 ft. away. The latter intersected the same rich orebody which the original shaft had cut.

The Ruby City Improvement Association has applied for \$150,000 cash from the Alaska Road Commission for the construction of a highway from Ruby to the various creeks in the district. Anderson & Bark found pay-ore recently in their prospect shaft at Dome City.

THE TANANA

Press despatches state that the richest gravel ever found in the Tanana valley has been discovered by Smith brothers on the Daly bench at the mouth of Eva creek.

ARIZONA

COCHISE COUNTY

The Boeckler Mining Co. is planning to use automobile trucks for transporting ore from its property to the station at Rodeo, a distance of 15 miles, says a recent report from Portal. The mine, which is in the Paradise district, formerly was operated by the Old Homestead company. The ore is shipped to the concentrator at Douglas.

GILA COUNTY

(Special Correspondence.)—The work of enlarging shaft No. 2 at the Live Oak mine has been completed. The third compartment was added by raising from three different points and the total distance of 925 ft. was accomplished in 40 days. The east drift on the twelfth level at the Superior & Boston has passed out of the ore-shoot in which it has been for some distance. For a distance of 25 ft. the drift was in ore for its full width, but the ore gradually narrowed down and pinched out. Hole No. 1 on the Barney group has been discontinued at a depth of 1450 ft. and is the deepest hole ever drilled in the district. The hole is bottomed in schist formation and is a flowing well. The strong flow of water in the dacite formation at a depth of 960 ft. is sufficient to supply the churn-drilling machines and for domestic use at the camp. Hole No. 3 will be started at once. Hole No. 2 is 370 ft. deep. Work will not be resumed on the Inspiration dam across Pinal creek until the present rains are over. The test mill will be started again in a few days, after the alterations have been completed. Topographic surveys are being made.

Globe, March 29.

YAVAPAI COUNTY

Reports from Prescott state that the Clara Consolidated company is being reorganized.

David Kile, C. J. Kimball, and J. H. Leibold have discovered a vein of vanadium, molybdenum, bismuth, and nickel ore on their property, two miles southwest of Crown King, according to newspaper despatches. The owners will thoroughly prospect the deposit.

CALIFORNIA

AMADOR COUNTY

(Special Correspondence.)—The Lincoln Con. M. Co., of this place, has acquired the Wildman-Mahoney properties from W. J. McGee, the consideration being 200,000 shares of the Lincoln stock, which has been increased from 400,000 shares to 800,000 shares, par value 50c. Stockholders and holders of preliminary certificates who have paid and are paying the company at the rate of 50c. per share have the option, up to May 1, of purchasing from Mr. McGee shares equal to their fully paid stock and preliminary certificates at the rate of 20c. per share, provided they purchase from the company an equal number at 50c. of the shares now in the treasury. If all of Mr. McGee's shares are not taken by May 1, he will return 10% of the remainder, which may

be used, if necessary, as a commission fund by the company in selling any of its shares not taken under the present offer. Both the Wildman and Mahoney mines have 40-stamp mills and other equipment. The Wildman has an assay office. It is planned to drive on the Wildman vein from the Lincoln shaft.

Jackson, March 30.

The suit brought by R. H. McIlwain against the Original Amador Mines Co. et al., asking for an accounting and the appointment of a receiver, has been dismissed. A stipulation conceded that there was no cause of action against the company, its officers, or the directors. The case was in the Oakland courts.

Work is to be resumed in the South Amador mine as soon as the concrete foundations for the surface machinery is laid. A new 15-ft. vein was discovered recently on the 500-ft. level. C. D. Porter is general manager for the company.

CALAVERAS COUNTY

The East Belt Development Co. has acquired the Tanner mine, near Murphys, and is shipping from the recently

CALIFORNIA BY COUNTIES.

discovered orebody, assays of which run as high as \$300 per ton. J. A. Campbell is superintendent for the company. G. S. Taylor has found rich float in his Legal Tender mine.

KERN COUNTY

The topographic map of the Randsburg quadrangle lying just south of the Mojave desert in southern California, has been reissued by the U. S. Geological Survey to conform with the revision survey made last year. The field work for the revision was done by T. P. Pendleton. The original map was prepared in 1900. In the map 50-ft. contour intervals are used, and a scale of one mile to the inch. Maps are for sale by the Geological Survey at 5c. each or \$3 per 100.

MODOC COUNTY

It is reported that Francis A. Smith and D. F. Sampson are planning to develop three veins on their Red Top and Hidden Treasure properties in the Lake City districts. The Red Top group has a 3-ft. vein assaying about \$14.90 per ton, and the Hidden Treasure a 6-ft. vein assaying between \$5 and \$7 per ton gold. The third vein has been only superficially prospected.

PLUMAS COUNTY

The Feather River Con. Mines Co., composed largely of

Cripple Creek men, has taken a bond on the Gold Leaf mine in the Argentine district. The 5-stamp mill on the Bluff City property will be moved to the Gold Leaf, and used as a testing plant. H. D. Thompson is president and Richard Blanchard superintendent for the company.

SIERRA COUNTY

The Sierra Standard G. M. Co. has been incorporated to develop the old Standard quartz mine in Sailor ravine. The capitalization is \$250,000.

COLORADO

CLEAR CREEK COUNTY

(Special Correspondence.)—The West Griffith mine on Griffith mountain has been taken under bond and lease by W. O. Robinson, representing a syndicate of Eastern men. Work has been put under way through the adit. The Josephine mine on Kelso mountain, West Argentine district, was sold by Fernor J. Spencer, trustee in bankruptcy, a few days ago for \$7500. J. C. Bell was the purchaser. The defunct company had debts totaling \$27,000. It is stated that work will start April 1. Oklun brothers, owners of the Scott property on Republican mountain, are shipping 10 tons of zinc per week. The ore mills 50% zinc and 30 oz. silver per ton. Occasional shipments of lead are being made.

Georgetown, March 29.

OURAY COUNTY

(Special Correspondence.)—The report of the Camp Bird, Ltd., for the quarter ended January 31 shows that the mill crushed 15,760 tons of dry ore. Receipts from bullion and cyanide products amounted to \$293,551, and from concentrate sold to \$172,998, making a total of \$466,549. Operating expenses amounted to \$115,867, leaving a net profit of \$350,682, or £71,861. The profit from the company's holdings in the Santa Gertrudis Co., Ltd., was £53,924, making the net profit £125,785. In addition to the above items, there was expended on construction \$388, or about £79, and on London and general expense of management about £900. A dividend of 2s. per share, for the six months ended January 31 was paid February 12.

Ouray, March 25.

The properties of the Revenue Tunnel Mines Co. and the Wheel of Fortune M. Co. are being operated under lease by the Revenue Leasing Company.

TELLER COUNTY (CRIPPLE CREEK)

Gildea & Prentice, lessees in the Gold Coin shaft of the Granite G. M. Co.'s property, have discovered high-grade ore on the 800-ft. level, where they intersected the Dorothy vein. Mrs. Jeannette McLean Williamson, of Colorado Springs, has bought the Black Hawk claim on Grouse mountain for \$700. The property, which formerly belonged to the Matt France M. & M. Co., was sold by the public trustee.

Cutting a water-course on the 1500-ft. level of the Indicator No. 1 shaft necessitated a temporary suspension of work there a short time ago. An air-lift made the resumption of work possible. Recent reports stated that the cross-cut on this level had 400 ft. to go before reaching the orebody. J. E. Graves and associates, lessees on the Little Mary claim, have discovered ore assaying \$20 to \$63 per ton. It is rumored that a sub-lessee in the Gold King mine has found exceptionally rich ore, but no details have been announced.

IDAHO

LATAH COUNTY

Aerial tramways furnished the subject of an illustrated lecture by R. S. McCaffery, head of the mining department of the University of Idaho, at the meeting of the Associated Miners of that institution on March 19. The association plans to visit British Columbia in the spring.

SHOSHONE COUNTY

Eugene R. Day, president of the Tamarack & Chesapeake M. Co. has confirmed the report that the Day interests have purchased the Brien holdings of 200,000 shares, also a num-

ber of claims on the same hill adjoining the property. As the Tamarack ore-shoot extends into the Custer mine, also controlled by the Days, it is understood the two properties will be consolidated. G. H. Martin, president of the Carbonate Hill M. Co., has received from the Department of the Interior, patents for the Carbonate Hill fraction and the Long John claims. This makes ten patented claims in the Carbonate Hill group. The total area now controlled by the company aggregates 200 acres. At the Carbonate Hill mine, according to advices received by Mr. Martin, a 10-ft. vein of ore, running \$80 to \$85 per ton has been found. The deposit was discovered about 1260 ft. from the entrance to the main adit, at a depth of 850 feet.

MONTANA

SILVERBOW COUNTY

(Special Correspondence.)—A report has been received here of a rich find in the Robert Emmet mine of which W. Q. Ranft is general manager and which is largely controlled by Boston and New York interests. In running a cross-cut on the 500-ft. level an 18-ft. vein of high-grade silver-lead ore was discovered. Work on this property had been suspended during the winter, but was resumed a week ago.

Mining interests in this district for more than a week were in a somewhat unsettled condition, due to an attempt on the part of the Socialists to make political timber of the fact that a number of men had been discharged from mines of the Anaconda company supposedly because they were affiliated with that party. Being in control of the offices of the miners' union, a committee was appointed to demand the reinstatement of the men discharged. This committee, on waiting on C. F. Kelley, resident director and vice-president of the company, was informed that there being no complaint as to violation of union rules on the part of the company, the men would not be put back, the company reserving the right to hire and discharge men at will, always of course hiring union men and paying union wages. This committee, which was composed of 23 Socialists and 2 conservative members of the organization, reported back to the union recommending a strike, the report being signed by the 23 Socialists. The report was rejected by an overwhelming majority and a report by the minority members was adopted recommending a referendum vote on the question. This vote was taken and the motion to go out on a strike was defeated by a big majority. The Socialists are now engaged in endeavoring to stir up trouble with the mine-owners over the question of wages. The five-year contract expired on April 1, but there is a clause which provides that 30 days notice must be given before it can become inoperative, so that whatever the radical element may decide on may be delayed. However, one thing has been pretty clearly established, that the conservative element is still in the majority by at least several hundred members and that nothing will be done to disturb the agreeable relations existing between the company and the union.

Butte, April 1.

NEVADA

ELKO COUNTY

George Wingfield is quoted in the *Elko Free Press* as stating that he abandoned his option on the Success group of claims largely because the owners did not permit him to make further exploration. He said that \$15,000 was due on the Success group on March 5, and as the lower adits had not intersected ore of commercial grade, he did not feel warranted in making the payment without first making further exploration. He also told the owners that he considered the price set too high. The owners declined his offer of making further exploration if the owners granted a "reasonable extension of the option and a satisfactory reduction in the purchase price." The option, together with options on the Bluster, was forfeited.

ESMERALDA COUNTY

(Telegraphic Correspondence.)—The Goldfield Con. M. Co. produced in March, according to the official estimate published by A. H. Howe, secretary of the company, 30,132 tons of ore, with a value of \$685,000. The operating ex-

penses of the month amounted to \$200,000, leaving a net profit of \$485,000.

Goldfield, April 3.

The Darms Coal M. Co. has been incorporated to develop the six claims owned by H. A. Darms at Coaldale. The incorporators include, besides Mr. Darms, Henry Darms and John J. Linder.

LYON COUNTY

(Special Correspondence.)—The smelter of the Mason Valley Mines Co. is treating about 600 tons of ore per day from the Mason Valley and Nevada Douglas mines. The ore from the former consists largely of sulphide, and from the latter of carbonate, with some sulphide present. The ores are practically self-fluxing, only about 5% of lime being employed in charging. The furnace is of the water-jacketed drop-bottom type. The matte is tapped into a casting machine and shipped to Garfield, Utah, for refining. Blast is furnished by two Connersville blowers. The second furnace probably will remain idle until facilities have been provided for larger shipments of ore from the mines. The Nevada Douglas mines, in the Ludwig district, reports in-

GOLDFIELD CON. CLERMONT SHAFT.

creasing activity. A suction pump has been installed on the seventh level of the inclined shaft, and sinking will soon be resumed. The present vertical depth is 750 ft. Three shifts are driving on the east vein to open the ore below the stope on the sixth level. In the Copper Casting portion of the property ore averaging 8 to 12% copper is said to be in evidence. In the Douglas Hill part about 20,000 tons is reported broken and ready for shipment.

Yerington, March 30.

NYE COUNTY

(Special Correspondence.)—The report of an important ore discovery in the Halifax mine has been confirmed. It is said the miners have penetrated 8 ft. of excellent ore, but the width of the orebody has not yet been determined. The new vein recently cut on the 1100-ft. level of the Belmont shows a width of 9 ft. It was intersected by south cross-cut No. 6 and lies west of the Belmont vein and east of the Belmont fault. No attempt will be made to mine the vein at this time, as the 40-stamp mill at Millers is operating at top capacity to handle the quartz from main workings. It is expected the new 600-ton mill will be ready for operation by June 1. It is officially stated that the Tonopah Extension Co. will immediately commence the sinking of a new main shaft, about 1600 ft. west of the present avenue. The shaft will have three compartments, each being 4½ by 5 ft. in the clear, and will make accessible the reserve recently opened in the westerly portion of the Tonopah Extension ground.

Tonopah, March 30.

The Manhattan Chamber of Mines has been organized to promote the interests of the Manhattan district. Homer L. Ross is president, Charles Kirchen vice-president, and Percival Nash secretary and treasurer of the organization. The management of the Steffner lease on the Manhattan Consolidated property, has announced that the shaft, now 200 ft. deep, will be sunk to a depth of 720 feet.

The production of the Tonopah district for the week ended March 30 is summarized as follows by the *Tonopah*

Miner: "The Tonopah M. Co. sent 3250 tons of ore, the Belmont company 2100 tons, the Montana-Tonopah 1014 tons, the Tonopah Extension 1065 tons, the West End 750 tons, and the MacNamara 365 tons, making the total production for the week 8544 tons of ore of which the estimated value was \$213,600."

The recently reorganized Tonopah Merger M. Co. is planning to start development soon on its property, which formerly was known as the Golden Anchor M. Co. mine.

STOREY COUNTY

The Ophir last week produced about 186 tons of ore, valued at \$5195. The Con. Virginia extended the three-compartment raise from the 2400-ft. level 7 ft., making the total length 23 ft. Two chutes were placed there. From this work about 31 tons of ore, averaging \$26.52, was saved. The Mexican mill ran 94% of the time during the week and crushed 553 tons of ore, the gross value of the 'heads' being \$12,874. The apparent extraction was 90%. The north drift from the south boundary in the Union Con. has been cleared from timbers, and seven sets were placed. Other repair work was done. The Crown Point continued production of low-grade ore from the 1400-ft. level, hoisting 491 cars of ore, of which 237 cars averaged \$7.31 per ton. The Comstock Pumping Association report shows that last Saturday the water was 291 ft. below the 2200-ft. station of the C. & C. shaft.

WHITE PINE COUNTY

The Zaek shaft will be sunk 200 ft. more, giving it a depth of 800 ft. A station will be cut at the 600-ft. level and a pump placed at that level. The pump is to have a capacity of 500 to 600 gal. per minute. The present pumps, raising 100 to 200 gal. per minute, are able to handle the present flow. The water, although having a trace of copper, is used in the boilers. Press reports state that the Steptoe smelter is treating about 10,000 tons of ore per day, eight units running at capacity. The Giroux company has paid the estate of each of six of the seven men killed in the fire last August \$1200. The heirs of D. F. Drea, the seventh man, refused, demanding a larger amount. On a compromise the heirs were given \$2000.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Ernestine M. Co.'s bullion product for the first 20 days of March was 13,790 oz. gold and silver, and concentrate for the period amounted to 21,000 lb. The ore treatment for the past two weeks was 1410 tons. The framework is being erected for a new Blake crusher, which will do away with the belt conveyor. It is probable that the Deadwood mill will not be able to resume operation before the first week in April.

The Oaks Co.'s platforms at the Pacific mine are filled with ore awaiting delivery to the Deadwood mill for treatment as soon as the engine at the latter is in commission. The South shaft is yielding fine ore as sinking progresses.

It is reported that a deal is pending whereby the entire holdings of the Mogollon Gold & Copper Co. will be taken over and active development started in a number of the mines.

Development in the Iron Group property has disclosed a large vein of low-grade ore.

Mogollon, March 29.

OREGON

SUMPTER COUNTY

The pebble mill formerly at the Cougar mine, near Granite, is to be erected soon at the Red Boy property, says a report from Sumpter. As the mill at its former situation was little used, the Red Boy's ore treatment will furnish the first thorough test of the equipment in eastern Oregon. Andre A. Groves has taken a lease on the Eppinger placer mine on Cow creek.

SOUTH DAKOTA

LAWRENCE COUNTY

(Special Correspondence.)—The Golden Reward company has given a number of leases on some of its smaller properties in the Bald Mountain district. One of the clauses in

all of the leases provides that the milling ore extracted shall be treated in the company's mill at Deadwood. The Mogul company is making regular shipments to the L. D. & W. mill at Terry. The ore supply is being drawn from the Lucille and Ben Hur mines, and it is the intention of the company to open the Hardscrabble property also. Mr. Dorr, the general manager, is planning to lease the Dakota mill at Deadwood in order to find an outlet for the ores. This plant has 30 stamps, and is well equipped in all departments except that for handling slime. The New Reliance company has placed 10 additional stamps, making 30 in all, and is awaiting good weather in order to get the new machinery in commission. E. M. Hiltner has resigned as superintendent, and William Weigand is now running the property. The Western Federation of Miners is planning to take over the property of A. H. Olson, which adjoins the Homestake on the south and east, and in the event that the deal is perfected will engage in mining on its own account. The property is partly developed by means of a 300-ft. shaft. The deal has progressed so far that the Federation is now endeavoring to secure funds to commence work.

Deadwood, March 28.

UTAH

JUAB COUNTY (TINTIC DISTRICT)

The Centennial Eureka recently disbursed \$150,000 in dividends at the rate of \$1.50 per share. All but 136 shares of the stock is held by the United States M. Co. Last year two dividends of similar size were paid. The Grand Central and Gold Chain mines now have W. D. Loose as superintendent, August Wetterstrom having resigned. The Grand Central has been temporarily shut down to permit lengthening the cable and repairing the shaft. The Eagle & Blue Bell is now below the 1300-ft. level.

SUMMIT COUNTY

(Special Correspondence.)—The Crowther Leasing Co. has a lease on the dump and practically all the workings of the old Ontario mine. It has been working on the property for some time, but the operation so far has been largely metallurgical experiments. Now the new mill, the construction of which is the result of numerous test runs, is approaching completion, and will be started next June. The Ontario is one of the oldest mines in Utah. The ore contains principally silver, although some of the veins have lead ore. Nearly all of the \$13,000,000 disbursed in dividends was paid from the profits from treatment by the chlorination process. In the early days the ores averaged \$100 and more silver per ton, and \$40 ore was declared unprofitable. Ore of this class was thrown over the dump, or used to fill in stopes. The Crowther company has been using the cyanide process with excellent results, and now is installing cyanide equipment in the old Ontario mill to make possible the treatment of 300 tons per day at the outset, with prospective increase to a capacity of 500 tons per day. Exhaustive sampling of the old stopes and dumps shows that the ore available will average about \$12 per ton.

Park City, April 2.

TOOELE COUNTY

(Special Correspondence.)—The new lead plant of the International S. & R. Co. has increased its capacity to 500 tons per day by blowing in the second lead stack. The plant is handling 200 tons per day from the Bullionville tailing at Pioche, and has recently added to its contracts. Work has started on the ten-mile branch of the Salt Lake railroad from St. John to Ophir. This branch is being built primarily to handle the ore from W. A. Clark's Ophir Hill mine, but it will greatly aid the Cliff, Lion Hill, and other properties in the district.

Tooele, April 2.

WASHINGTON

FERRY COUNTY

The Factor M. Co., operating at Orient, elected officers as follows, at the annual meeting in Spokane: President, G. R. Horley; vice-president, J. M. Gunning; secretary and treasurer, J. E. Pickrell; general manager, A. O.

Evans. A. J. Bell was elected to the board of directors. The secretary's report states the company and property are in good condition. Development will be continued throughout the year.

STEVENS COUNTY

The Liberty Copper M. & M. Co. is planning to build a 100-ton concentrator on its property at Blue Creek, north of Chewelah. S. G. Neff, manager of the mine, has announced that the company plans to sink from the 270-ft. level a depth of 50 ft. and to stope from that level.

BRAZIL

MINAS GERAES

(Special Correspondence.)—The Diamond King Mining Co., the only dredging company at work in this district, reports that within a few months a railroad will be built which will reduce its wagon haul from 100 to 12 miles. Placer mining has been carried on in this district since 1600, and there are also many excellent opportunities for gold mining in quartz. During the time of the Portuguese these were worked as open-cuts, but little has been done since 1878, when the slaves were freed. Many of these slaves have since been mining for themselves, with varying degrees of success.

Diamantina, February 20.

CANADA

ONTARIO

The American Eagle M. Co. has been incorporated at Toronto. The provisional directors are W. A. Chase, J. B. Taylor, and E. R. Thompson. The Smith & Durkee Diamond Drilling Co., capitalized at \$40,000, has been incorporated at Sudbury. The directors of the company are O. P. Smith, C. A. Durkee, and E. T. Lansdowne.

MEXICO

New York Associated Press despatches on March 28 reported that all wire communication with Mexico City had been cut off. Whether the suspension was due to censorship or wire-cutting was not known.

JALISCO

The murderers of Thomas Murphy, late manager of the El Favor mine, Hostotipaquillo district, were arrested at the Zopilote mine on March 24. The murderers, two brothers, Cervantes by name, shot Mr. Murphy in April 1911. Since then they worked under assumed names at the Purisima and Zopilote properties.

SONORA

(Special Correspondence.)—Intervention would be a great calamity, it is believed here, and the general hope is that the Madero government will survive. Sonora is happily free from open disturbances by the Vasquista and Pasqualista forces, but there is, or has been, much pillaging by bands of 'horseback hoboos.'

Yzabal, March 29.

Mexican 'high-graders' have been stealing ore from the Cinco de Mayo and other properties, asserts a despatch from Douglas by way of El Paso, and in some cases boldly send the filched ore to the smelters. Usually the thieves concentrate it themselves with crude apparatus. The first shipment of ore from the San Nicholas, near Nacozari, under bond to Frank U. Borgeson and associates of Bisbee, recently passed through Douglas. Mr. Borgeson is superintendent of the property, on which about 20 men are employed.

NICARAGUA

(Special Correspondence.)—The Topaz M. Co. has intersected the Mico vein on the No. 4 level, 292 ft. from the surface. Where cut, the vein is about 20 ft. wide, and assays average \$15 per ton. The ore is oxidized. At a point 100 ft. above and 100 ft. east, the ore ran about \$22 per ton. The company, which was organized under the laws of the Republic of Nicaragua, has its main office at Bluefields. It has a 20-stamp mill, the stamps being 850 lb. each. The property is in the Rama district.

Bluefields, March 15.

PERU

Ferrobamba, Ltd., has over 7,500,000 tons of ore partly developed in two mines, according to a recent announcement by W. F. Stevens, mine manager for the company. The property is at Ferrobamba, Catobambos, Apurimac. Adits No. 1 to 18 in the Ferrobamba No. 1 mine have shown 6,000,000 tons of ore assaying about $4\frac{1}{2}\%$ copper and over $1\frac{1}{4}\%$ sulphur. Adit No. 1 of the Sulfobamba has about 778,000 tons assaying $2\frac{1}{4}\%$ copper and $2\frac{1}{4}\%$ sulphur. Adit No. 2 of the same mine has 532,400 tons carrying a little more than $\frac{1}{4}\%$ copper and $3\frac{3}{8}\%$ sulphur. Satisfactory tests proving the suitability of Ferrobamba No. 1 ore to treatment by a modified concentration have been made.

Among the Copper Mines

The UTAH COPPER Co. will have thirteen sections in the Arthur mill completed by August 1, according to recent reports. The ninth unit is about ready now. If the production from the mines can be increased the mill will be run at capacity in August, treating 20,000 tons of ore per day.

The BUTTE-ALEX SCOTT is shipping 150 tons of ore per day to the East Butte smelter, and it is more than likely that in the next two weeks the output will be increased to 200 tons per day, which will be the capacity of the hoisting machinery. The ore is all coming from the 1600 and 1700-ft. levels and averages 6% copper.

GREENE-CANANEA produced 2,948,000 lb. of copper in February, as compared with 3,552,000 lb. in January, the falling off being due to trouble with the machinery which has since been remedied. The silver production in February was 104,512 oz., against 100,681 in January, and the gold 526 oz. in February and 493 oz. in January. It is stated that so far the operations have not been affected on account of the disturbed political conditions in Mexico.—*Boston Commercial*.

The OHIO COPPER report for February shows a profit of \$37,117. Copper production amounted to 757,207 lb., obtained from 51,924 tons of ore averaging about 1.3% copper. Losses in tailing were 43.71%. An examination of the property is being made by Henry Krumb, which it is believed will have an effect on future financing. The mill treated an average of 1790 tons per day during February, with two units in operation. The completion of two more units will double its capacity.

The NORTH BUTTE dividend of 40c. per share, just declared, clearly puts at rest all questions as to its earning capacity. While nothing is being done on the 2800-ft. level just now, nor will be until connection is established with the High Ore in order to provide good ventilation, the 2200-ft. level of the Snowball is providing all the high-grade ore required for shipment. Between it and the Berlin vein the reserve supply is being constantly added to and the company could today easily increase its production at least 500,000 lb. of copper more per month than was produced in February or March.

BINGHAM MINES had on hand December 31, \$76,593, this amount remaining after \$32,655 for bond interest had been deducted from the \$109,248 earned by the company last year. Under the terms of the mortgage the only use to which this \$76,593 can be put is the purchase and retirement of first-mortgage bonds. It will be recalled that \$33,000 of these bonds were retired last year with the surplus net earnings of 1910, leaving \$536,000 outstanding. As at least \$3000 will be available from other sources, the management expects to purchase and cancel \$80,000 or more of the remaining bonds in April or May.—Walker's Letter in *Boston Commercial*.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

A. C. VEATCH is here.

T. LANE CARTER is in Mexico.

N. GUNDY was in San Francisco.

A. P. WILSON has gone to Alaska.

W. F. POWELL is in San Francisco.

A. D. McRAE is visiting San Francisco.

JAMES R. HAYDEN is at the St. Francis.

R. L. BEALS has returned from Mexico.

VICTOR VON GROOT is visiting California.

E. B. KIMBALL is on his way to London.

F. O. JASMER is in San Antonio, Texas.

A. CHESTER BEATTY is in San Francisco.

EDWIN ARKELL was here during the week.

F. G. COTTRELL has returned to San Francisco.

W. H. ALDRIDGE was at Miami, Arizona, recently.

STEWART BLACKBURN is now at Mineral Hill, Nevada.

R. H. ELLIOTT is on his way to California from the Gold Coast Colony.

T. A. RICKARD is in Denver and will leave for New York early in the week.

PALMER CARTER has resigned from the management of the Ferreira mine.

VICTOR G. HILLS has returned to Denver from Moose river, Nova Scotia.

ROSCOE H. CHANNING was recently in San Francisco and is now in Arizona.

VICTOR E. TULL has gone to Seattle for the summer and is at 211 Coleman building.

GEORGE W. STARR has gone to Panama and New York, and will visit Arizona and Nevada.

C. COLCOCK JONES has returned to Los Angeles from a trip to Douglas county, Nevada.

GEORGES LE ROYER has returned from Buenos Ayres and will spend several months in Paris.

LAWRENCE N. WAGNER will leave during the week for a trip to Europe by way of Panama.

R. B. LAMB has gone to Poreupine to inspect the properties there with which he is connected.

F. C. SHRADER has completed a preliminary geological examination of the Antelope district, Nevada.

E. E. GLEDHILL has left for Ungava to make explorations for the Ungava Exploration Company.

W. L. SAUNDERS will make the address at the annual commencement of the Colorado School of Mines, May 24.

F. L. SIZER, who is now at Doz Cabezas, New Mexico, has become consulting engineer for the Mascot Copper Company.

S. F. SHAW is superintendent of the Tiro General mine of the American Smelting & Refining Co. at Charcas, San Luis Potosi.

ALBERT L. WATERS, recently manager for the Pioneer Smelting Co. of Tucson, is now chancellor of the University of Arizona.

JOHN C. DERN has resigned as manager for the Lower Mammoth Mining Co. at Tintie, Utah, to be succeeded by JAMES C. DICK.

EDWARD L. HAFF has been appointed superintendent of the Amalgamated Nevada mine in the Blackhorse district near Ely, Nevada.

FRANK H. PROBERT announces that the firm of Weed & Probert has been dissolved by mutual consent, and that he will continue practice at Los Angeles.

LOCAL METAL PRICES

San Francisco April 4.

San Francisco is not a primary market for the common metals except quicksilver. The prices quoted below therefore represent sales of small lots and are not such as an ore-producer could expect to realize. Ore contracts usually call for settlements on the basis of Eastern prices, less freight and treatment charges. The prices quoted are in cents per pound, except in the case of quicksilver, which is quoted in dollars per flask of 75 pounds.

Antimony..... 11-11½c	Quicksilver (flask)..... 43.50
Electrolytic Copper..... 16-16½c	Tin..... 47-48½c
Pig Lead..... 4.45-5.40c	Spelter..... 7½-7¾c
Zinc dust, 1400 lb. casks, per 100 lb., small lots \$9.50-9.75; large \$7.50-8.50	

METAL PRICES

(By wire from New York.)

Average daily prices in cents per pound, based on wholesale transactions, standard brands.

Date.	Electrolytic Copper.	Lead.	Spelter.	Silver, per oz.
Mar. 28.....	15.34	4.20	6.48	58½

SILVER

Below is given the average New York quotation, in cents per ounce, of fine silver for the months indicated:

	1911.	1912.		1911.	1912.
Jan.	53.81	56.25	July	52.57	...
Feb.	52.23	59.06	Aug.	52.17	...
Mch.	52.76	58.37	Sept.	52.43	...
Apr.	52.32	...	Oct.	53.37	...
May	53.31	...	Nov.	55.77	...
June	53.04	...	Dec.	54.85	...

LEAD

Lead is quoted ordinarily in cents per pound or dollars per hundred pounds delivered at St. Louis or New York. The difference is normally 15c. per hundred pounds, and any larger or smaller difference is promptly met by sales. The daily price in New York is published each week in this column. Below are the average quotations by months:

	1911.	1912.		1911.	1912.
Jan.	4.48	4.43	July	4.50	...
Feb.	4.44	4.03	Aug.	4.50	...
Mch.	4.39	...	Sept.	4.48	...
Apr.	4.41	...	Oct.	4.27	...
May	4.37	...	Nov.	4.30	...
June	4.34	...	Dec.	4.45	...

ZINC

Zinc is quoted as spelter, standard Western brands, and based upon St. Louis or New York delivery. While New York quotations, as a matter of convenience, are commonly used, relatively little spelter actually goes to or comes from New York. The bulk is shipped direct from the plants in the Mississippi Valley to manufacturers, due allowance being made for freight. New York daily quotations are published in this column each week. Below are given averages by months:

	1911.	1912.		1911.	1912.
Jan.	5.45	6.42	July	5.70	...
Feb.	5.52	6.50	Aug.	5.95	...
Mch.	5.56	6.57	Sept.	5.86	...
Apr.	5.40	...	Oct.	6.10	...
May	5.35	...	Nov.	6.38	...
June	5.50	...	Dec.	6.30	...

QUICKSILVER

The primary market for quicksilver is San Francisco, California being the largest producer. The price is fixed in the open market, and, as quoted weekly in this column, is that at which moderate quantities are sold. Buyers by the carload can usually obtain a slight reduction, and those wanting but a flask or two must expect to pay a slightly higher price. Average monthly quotations in dollars per flask of 75 lb., are given below:

	1911.	1912.		1911.	1912.
Jan.	44.60	43.75	July	48.00	...
Feb.	48.40	46.00	Aug.	50.00	...
Mch.	52.50	46.00	Sept.	47.50	...
Apr.	50.90	...	Oct.	46.12	...
May	46.50	...	Nov.	45.50	...
June	46.50	...	Dec.	44.50	...

TIN

New York prices control in the American market for tin, since the metal is almost entirely imported. San Francisco quotations, averaging about 5c. per lb. higher than New York, are quoted weekly in this column. Below are given average monthly New York quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	41.25	42.53	July	42.40
Feb.	41.61	42.96	Aug.	43.32
Mch.	40.16	42.50	Sept.	39.75
Apr.	42.18	Oct.	41.18
May	43.11	Nov.	43.12
June	44.61	Dec.	44.65

COPPER

Daily quotations on copper as published in this column represent average wholesale transactions on the New York market and refer to electrolytic copper. Lake copper commands normally from 1-5 to 1-4c. per lb. more. Below are average monthly quotations in cents per pound:

	1911.	1912.		1911.	1912.
Jan.	12.29	14.09	July	12.47
Feb.	12.26	14.08	Aug.	12.41
Mch.	12.14	14.68	Sept.	12.20
Apr.	12.02	Oct.	12.19
May	11.99	Nov.	12.61
June	12.39	Dec.	13.55

COPPER SURPLUS

Figures showing the visible supply of copper at the beginning of each month are now widely available. Below are given the amounts, in pounds, known to be available at the first of each of certain months.

		U. S.	European.
January	1910	141,766,111	244,961,280
January	1911	122,030,195	230,264,280
July	"	157,434,164	195,937,280
September	"	133,441,501	191,215,360
October	"	140,894,856	191,945,600
November	"	134,997,642	176,816,640
December	"	111,785,188	164,151,680
January	1912	89,454,695	178,329,920
February	"	66,280,643	153,820,800
March	"	62,939,988	141,142,400

UNITED STATES PRODUCTION AND CONSUMPTION

(Compiled from reports of the Copper Producers' Association)

	Production.	Domestic deliveries.	Exports.
March, 1911	130,532,080	66,080,789	59,081,127
April	118,185,223	52,407,650	62,129,599

June	124,554,312	61,655,561	71,460,519
July	112,167,934	56,982,582	74,880,658
August	125,493,667	59,935,364	69,885,660
September	115,588,950	57,311,584	50,824,011
October	118,255,442	64,068,656	60,084,349
November	111,876,601	68,039,776	67,049,279
December	122,896,697	65,988,474	79,238,716
Total for 1911	1,431,938,338	709,611,945	754,932,733
January 1912	119,337,753	62,343,901	80,167,904
February	116,035,809	56,228,368	63,148,096

Current Prices For Chemicals

(Corrected monthly by Braun-Knecht-Heimann Co.)

Prices quoted are for ordinary quantities in packages as specified. For round lots lower prices may be expected, while in smaller quantities advanced prices are ordinarily charged. Prices named are subject to fluctuation. Other conditions govern Mexican and foreign business.

	Min.	Max.
Acid, sulphuric, com'l, 66°, drums, per 100 lb.	\$0.75	\$1.00
Acid, sulphuric, com'l, 66°, carboy, per 100 lb.	1.00	1.50
Acid, sulphuric, C. P., 9-lb. bottle, bbl., per lb.	0.13	0.18
Acid, sulphuric, C. P., bulk, carboy, per lb.	0.09 1/2	0.12
Acid, muriatic, com'l, carboy, per 100 lb.	1.60	3.00
Acid, muriatic, C. P., 6-lb. bottle, bbl., per lb.	0.15	0.20
Acid, muriatic, C. P., bulk, carboy, per lb.	0.10 1/2	0.15
Acid, nitric, com'l, carboy, per 100 lb.	5.25	6.50
Acid, nitric, C. P., 7-lb. bottle, bbl., per lb.	0.16	0.22
Acid, nitric, C. P., bulk, carboy, per lb.	0.12 1/2	0.15
Argols, ground, bbl., per lb.	0.20	0.25
Borax, cryst. and conc., bags, per 100 lb.	2.75	3.85
Borax, powdered, bbl., per 100 lb.	3.00	4.00

Borax glass, gd. 30 mesh, cases, tin lined, per 100 lb.	10.00	13.00
Bone ash, 60 to 80 mesh, bbl., per 100 lb.	4.50	5.50
Bromine, 1-lb. bottle, per lb.	0.55	0.65
Candles, adamantline, 12 oz., 40 sets, per case.	3.50	4.15 1/2
Candles, adamantline, 14 oz., 40 sets, per case.	4.00	4.55
Candles, Stearic, 12 oz., 40 sets, per case.	4.95	5.50
Candles, Stearic, 14 oz., 40 sets, per case.	4.65	5.20
Clay, domestic fire, sack, per 100 lb.	1.50	2.00
Cyanide, 98 to 100%, 100-lb. case, per lb.	0.20 3/4	0.24 1/2
Cyanide, 98 to 100%, 200-lb. case, per lb.	0.20	0.24
Cyanide, 129%, 100-lb. case, per lb.	0.27 1/2	0.28 1/2
Cyanide, 129%, 200-lb. case, per lb.	0.26 1/2	0.27 1/2
Lead acetate, brown, broken casks, per 100 lb.	8.75	9.65
Lead acetate, white, broken casks, per 100 lb.	10.00	10.25
Lead acetate, white, crystals, per 100 lb.	11.75	12.25
Lead, C. P., test., gran., per 100 lb.	13.00	15.00
Lead, C. P., sheet, per 100 lb.	15.00	18.00
Litharge, C. P., silver free, per 100 lb.	10.50	13.00
Litharge, com'l, per 100 lb.	7.50	9.00
Manganese ox., blk., dom. in bags, per ton	20.00	25.00
Manganese ox., blk., Caucasian. In casks, per ton	42.50	50.00
(25% MnO2-3% Fe)		
Nitre, double ref'd, small cryst., bbl., per 100 lb.	7.00	8.00
Nitre, double ref'd, granular, bbl., per 100 lb.	6.50	7.50
Nitre, double ref'd, powdered, bbl., per 100 lb.	7.25	8.00
Potassium bicarbonate, cryst., per 100 lb.	12.00	15.00
Potassium carbonate, calcined, per 100 lb.	15.00	18.00
Potassium permanganate, drum, per lb.	0.11	0.12 1/2
Silica, powdered, bags, per lb.	0.03	0.05
Soda, carbonate (ash), bbl., per 100 lb.	1.50	1.75
Soda, bicarbonate, bbl., per 100 lb.	2.00	2.50
Soda, caustic, ground, 98%, bbl., per 100 lb.	3.15	3.50
Soda, caustic, solid, 98%, drums, per 100 lb.	2.65	2.85
Zinc shavings, 850 fine, bbl., per 100 lb.	11.50	12.25
Zinc sheet, No. 9-18 by 81, drum, per 100 lb.	10.00	11.25

Current Prices for Ores and Minerals

(Corrected monthly by Atkins, Kroll & Co.)

The prices are approximate, subject to fluctuation, and to variation according to quantity, quality, and delivery required. They are quoted, except as noted, f.o.b. San Francisco. Buying prices marked *.

	Min.	Max.
Antimony ore, 50%, per ton	*\$20.00	\$22.50
Arsenic, white, refined, per lb.	0.03 1/2	0.04 1/2
Arsenic, red, refined, per lb.	0.08	0.09
Asbestos, according to length and quality of fibre, per ton	100.00	350.00
Asbestos, lower grades, per ton	10.00	90.00
Asphaltum, refined, per ton	15.00	20.00
Barium carbonate, precipitated, per ton	42.50	45.00
Barium chloride, commercial, per ton	42.50	45.00
Barium sulphate (barytes), prepared, per ton	20.00	30.00
Bismuth ore, 10% upward, per ton	*75.00 upward	
Chrome ore, according to quality, per ton	10.00	12.50
China clay, English, levigated, per ton	15.00	20.00
Cobalt metal, refined, f. o. b. London, per lb.	2.50	
Coke, foundry, per 2240 lb.	13.50	15.00
Diamonds:		
Borsts, according to size and quality, per carat	2.00	15.00
Carbons, according to size and quality, per carat	50.00	90.00
Feldspar, per ton	5.00	25.00
Firebrick:		
Bauxite, per M	175.00	
Magnesite, per M	190.00	275.00
Silica, per M	42.50	47.50
Flint pebbles for tube-mills, per 2240 lb.	16.50	22.50
Fluorspar, per ton	10.00	15.00
Fullers earth, according to quality, per ton	20.00	30.00
Gilsonite, per ton	35.00	40.00
Graphite:		
Amorphous, per lb.	0.01 1/2	0.02 1/2
Crystalline, per lb.	0.04	0.13
Gypsum, per ton	7.50	10.00
Infusorial earth, per ton	10.00	15.00
Magnesite, crude, per ton	7.50	10.00
Magnesite, dead calcined, per ton	23.50	27.50
Magnesite, brick (see firebrick).		
Manganese ore, oxide, crude, per ton	10.00	25.00
Manganese, prepared, according to quality, per ton	30.00	70.00
Mica, according to size and quality, per lb.	0.05	0.30
Molybdenite, 95% MoS2, per ton	400.00	500.00
Monazite sand (5% thorium), per ton	150.00	200.00
Nickel metal, refined, per lb.	0.45	0.60
Ochre, extra strength, levigated, per 100 lb.	2.25	3.25
Platinum, native, crude, per oz.	40.00	45.00
Sulphur, crude, per ton	15.00	25.00
Sulphur, powdered, per ton	40.00	45.00
Talc, prepared, according to quality, per ton	20.00	50.00
Tin ore, 60%, per ton	450.00	475.00
Tungsten ore, 65%, per ton	390.00	455.00
Vanadium ore, 15%, per ton	150.00	180.00
Wolframite (see tungsten ore).		
Zinc ore, 50% up, per ton	*15.00	20.00

Company Reports

AMERICAN SMELTING & REFINING COMPANY

This company was incorporated in New Jersey in 1899, and has an authorized capital of \$115,000,000 in 500,000 7% cumulative preferred shares and 650,000 common shares of \$100 each. All the preferred and 500,000 shares of the common stock have been issued. This company owns all the capital stock of the United States Zinc Co. and all the common stock of the American Smelters Securities Co., which has a capital of \$77,000,000. For this reason the balance-sheets of the two companies have been combined in this report, which covers the year 1911. As the last published report covered the period April 30, 1910, to April 30, 1911, it has been necessary to readjust accounts by deducting from the balance for April 30, 1911, the earnings for the calendar year included therein, and other profit and loss items. During the year, \$2,131,692 was expended on new properties and construction, of which \$600,000 was for the uncompleted smelting plant at Hayden, Arizona. During the year \$1,429,066 was written off for depreciation of property. The consolidated income account is as follows:

<i>Earnings of Smelting and Refining Plants and Industries immediately dependent on their operations:</i>	
Total before deducting Ordinary Repairs and Replacements	\$14,045,334.56
Less Ordinary Repairs and Replacements..	1,944,573.38
	\$12,100,761.18
<i>Earnings from Mining Properties.....</i>	2,000,186.79
<i>Other Earnings and Income.....</i>	1,011,177.33
Gross Income	\$15,112,125.30
<i>Deduct:</i>	
Corporate and Excise Taxes.....	114,198.06
Administrative Expense	767,982.19
Appropriation for Depreciation and Amortization of Property	1,887,399.07
Total Deduction	\$ 2,769,579.32
Net Income before deducting Fixed Charges and Dividends	\$12,342,545.98
<i>Deduct Fixed Charges and Preferred Stock Dividends:</i>	
Interest and Discount on American Smelters Securities Co. 6% Debenture Bonds (Feb. 1 to Dec. 31, 1911).....	870,833.34
Dividend American Smelting & Refining Co. Preferred Stock 7%.....	3,500,000.00
Dividend American Smelters Securities Co. Preferred A Stock 6%.....	1,020,000.00
Dividend American Smelters Securities Co. Preferred B Stock 5%.....	1,500,000.00
	\$ 6,890,833.34
Net Income in excess of Fixed Charges and Preferred Stock Dividends	\$ 5,451,712.64
<i>Deduct:</i>	
Dividend on American Smelting & Refining Co. Common Stock 4%.....	2,000,000.00
Surplus Income for the year carried to Profit and Loss Account	\$ 3,451,712.64
PROFIT AND LOSS ACCOUNT	
Surplus at January 1, 1911, adjusted as to changes made in 1911 directly applicable to prior period	\$11,148,223.67
Surplus Income for calendar year 1911, as shown on statement of Income Account....	3,451,712.64
	\$14,599,936.31
<i>Deduct:</i>	
Special Appropriation for Depreciation in value of Investments	\$ 900,210.00
Surplus at December 31, 1911, as per Consolidated General Balance Sheet	\$13,699,726.31

Book Reviews

Any of the books noticed in these columns are for sale by, or can be procured from, the MINING AND SCIENTIFIC PRESS.

MICROPETROLOGY FOR BEGINNERS. By J. E. W. Rhodes. Pp. 126. Ill. Longmans, Green & Co., London, 1912. For sale by the *Mining and Scientific Press*. Price \$0.90.

Of textbooks on petrography there is no lack, and the American student is commonly introduced to the volumes by Liqueur, Winchell, or Iddings at the outset of his petrographical career. But the last two of these are large volumes and all three discussed the subject upon so high a technical plane that many students find the pace too hard going, while a beginner who may wish to teach himself something of the elements of the subject, is likely to be completely swamped in a terminology beyond his comprehension. Mr. Rhodes has earned the gratitude of all such by affording them a simple brief outline of what is now an essential phase of the study of geology, and the moderate price at which it is published is also an advantage. The book is simply written and well illustrated, but has the two drawbacks of employing terms not current in America and of portraying a typical set of British rocks, rather than universal rock types. For this reason the American beginner should proceed as early as possible to correct his first ideas by a study of the more extended treatises by American writers.

APPLIED METHODS OF SCIENTIFIC MANAGEMENT. By Fred-eric A. Parkhurst. Pp. 314, index, 39 illustrations. John Wiley & Sons, New York. For sale by the *Mining and Scientific Press*. Price \$2.

As stated in the preface, this work is an amplification of the author's articles published in *Industrial Engineering* during 1911, and is based primarily upon the experience and results obtained by the organization of the Ferracute Machine Co., makers of presses and dies at Bridgeton, New Jersey. The application of scientific management in this particular instance is an excellent example of what may be accomplished in the way of improved factory organization when the product manufactured is comparatively homogeneous in its character. Each section of the company organization is treated individually and its functions specifically and clearly defined in order to prevent the frequent encroachment of one department upon the duties of another, which is one of the most glaring faults of the old-time systems (if they may be so called). The importance of standardizing shop methods and tools is rightfully emphasized. The tabulated labor cost comparisons of the old and new methods make a striking exhibit of the thorough practicability of scientific management, showing in many cases a saving of from 50 to 80%, while wages, on the other hand, increased from 15.9c. per hour to 26.7c. per hour, and the average working day reduced to 8.2 hours. The various forms, blanks, and memoranda used for shop purposes and interdepartment communication are illustrated in full and their use and application described at length.

While we do not know of an instance where an attempt has been made to apply the principles of scientific management to a manufacturing plant turning out a heterogeneous product or engaged in a general jobbing business, we know of no reason why the fundamental principles involved should not ultimately find a ready application to any set of conditions when labor is employed in the fabrication of material. Mr. Parkhurst rightfully emphasizes the fact that each specific case must be the subject of individual study and attention, and that no set rules could possibly be laid down that would be applicable to each case, but a thorough understanding of principles involved may be acquired through study of the results attained by experts, and the manufacturer can then either work out his own salvation—or, better, secure the services of a specialist who has been successful in the introduction of scientific management elsewhere. The general reader will find helpful suggestions throughout the work.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

FIREPROOF wash that is cheap and fairly good may be made by dissolving $1\frac{1}{2}$ lb. salt in 1 gal. whitewash.

WHITENING powder consists of 4 lb. magnesium carbonate, 4 lb. chalk, and 4 lb. rouge, intimately mixed.

CELLULOID can be fastened to wood or tin by the use of the following compound: Shellac, 2 parts; spirits of camphor, 3 parts; strong alcohol, 4 parts.

FINE solder is an alloy of two parts of block tin and one part of lead. Glazing solder is equal parts of block tin and lead. Plumbing solder, one part block tin and two parts lead.

NORMAL price of a metal may be defined as the price which will induce a steady increase in production, and also a reasonable amount of expenditure in discovering and developing new deposits.

HAND-DRIVEN ventilating fans are employed in the salt mines of Hungary, the air being carried to the face through 4.5-in. zinc or canvas pipes. The latter are cheaper, but soon wear out and allow a good deal of air to escape.

CYANITE is a basic metasilicate of alumina which occurs in long blade-like triclinic crystals of a blue color, usually paler along the edges. The name should be pronounced as though spelled kyanite, in order to distinguish it from syenite, the rock.

PIPE VISES can be easily made from old carpenter's vises. Take an old coarse rasp, break it in two, and draw the temper at the ends to allow drilling and countersinking for screws, which should be used to fasten the two halves to the jaws of the vise. Fasten one with the teeth pointing up and the other with the teeth down.

A SMALL cartridge containing ammonium carbonate, 65%; potassium bichromate, 33%; and camphor, 2%, used in holes containing high explosives, will render the gases inoffensive, according to S. W. Young. A somewhat cheaper composition which he proposes is a mixture of 65 parts ammonium carbonate and 35 parts of manganese dioxide.

FOREIGN coins are sometimes of very small value. In Russia the quarter-kopek contains 0.819 gm. copper and is worth 0.124c., and the Japanese 5-rin piece, which is 95% copper, 4% tin, and 1% zinc, weighs 0.711 gm., is worth 0.249c. The modern Chinese cash, which is a small round coin, without any hole in the centre, is worth about 0.04 cent.

PERILLA oil is somewhat similar to linseed, and is used in Japan for waterproofing umbrellas and for preparing transparent paper for windows. Compared with linseed oil it has equal spreading power, dries slower, and gives a better film. Experiments tried in Ohio indicate that the yield per acre is less than with flax and there are no useful by-products.

GLASS can be drilled by tempering the drill by heating to a cherry-red and plunging in mercury. Drill part way through from one side, and then finish from the opposite side. This will make a good clean cut and prevent chipping the edges of the hole. Apply sufficient pressure to make the drill 'bite' at all times, and keep the drill-point moistened with a mixture of two parts turpentine to one part sweet oil.

CUSTOM smelting in Colorado was started by N. P. Hill, who built a smelter at Blackhawk in 1867, consisting of a calcining furnace and a small reverberatory. The firebrick were shipped by rail from St. Louis to the terminus of the road, and then 600 miles by wagon. The iron cost 22c. per pound and skilled labor \$8 to \$10 per day. The smelting charges were \$20 to \$45 per ton and the matte was hauled to the Missouri and shipped by way of New York to Swansea for resmelting. The plant was in operation until 1887, when it was removed to Argo, near Denver.

LUBRICATION is one of the most important uses of graphite. The addition of graphite to oil results in a lower frictional resistance than would be obtained by the use of oil alone. The quantity of oil required for a given service is also reduced and a lighter grade of oil or one of inferior quality may be employed without decreasing the quality of the lubrication. A small quantity of graphite only is required, and the benefits derived from its use persist long after the application has ceased. In light bearings of machinery where oil cannot be used on account of the danger of soiling delicate textiles, graphite can be used alone as a lubricant. Both the amorphous and the crystalline varieties of natural graphite are extensively employed for lubrication. The artificial graphite manufactured at Niagara Falls is also largely utilized in this way, and the Acheson company has secured a product termed 'deflocculated graphite' which it is claimed shows little or no tendency to sink when mixed with oil or water, and when suspended in water will pass through the finest filter paper made. The suspension is obtained by adding small quantities of gallotannic acid and other substances to the medium carrying the graphite. Some attempt has been made to utilize a mixture of graphite and water for lubricating purposes. Such a mixture, although perhaps less liable to produce rust than water alone, is not a rust preventive and is not so safe for steel bearings as a mixture of oil and graphite.

MILL-SITES shall not be adjacent to the vein or lode, according to the statute. The Land Department has interpreted this as being an attempt to prevent the obtaining of further mineral ground under an improper location or entry, and has ruled that a mill-site may be in contact with the side line of a claim if it is clearly not an appropriation of more mineral ground—that is, the mill-site must be strictly non-mineral. A further application of this principle would allow locating and patenting mill-sites in contact with the end lines, where it can be conclusively shown that the mill-site is non-mineral and that its entry should be allowed. Since the statute is silent regarding the method of locating mill-sites, it is customary to follow very much the same methods as in making a lode location. Mill-sites should be square or rectangular, with a post at each corner. A single mill-site cannot exceed five acres in area. Five acres equals a tract 466.7 ft. square, or 217,800 sq. ft. A location notice should be placed upon the ground and also recorded. Mill-sites are usually named after the claim or group to which they are appended. When a claim or group including a mill-site, is surveyed for patent, the same survey number is used for both, but the number on the lode locations is followed by A, as '4785 A', while the same number used on the mill-site is followed by B, as '4785 B'. Letters are also used in patent surveys in some surveyor-general offices when lodes and placers are included in the same application. Mill-sites may be located at the time of location of their lode claim or claims, or at any time thereafter, even after patent. A single mining claim is entitled to a mill-site location. A group of mining claims, according to the rulings of the Land Department, is entitled to as many mill-site locations as it actually and reasonably needs, and no more. Consequently not more than one mill-site location should be made in connection with a group of lode claims, unless the locator is able to show, in subsequent entry for patent or adverse suits, that all of such claims are necessary.

A New Mine Suspension

The type B-3 mine suspension recently introduced by the Westinghouse Electric & Mfg. Co. of East Pittsburg, Pennsylvania (described in folder 4224) is unique in the simplicity of the clamp used. This clamp has only three parts, which cannot be taken apart, and therefore are never dropped or lost.

Because of its simplicity the clamp can be installed quickly and cheaply. The clamp complete, with nut loosened, is screwed on the insulator stud; the wire is inserted in the lips of the clamp and slips freely into place without the

least forcing; then the nut is tightened. Screwing down the nut clamps the wire firmly and also clamps the stud, so that the ear can be placed in any direction and yet be tight on the stud. This makes it unnecessary to twist the insulator after screwing the ear up tight.

The wire can be drawn through for taking up slack by simply loosening the nut. This does not permit the wire to drop out.

All parts of the clamp are sherardized, and perfect clearance for the trolley wire is provided. A wrench is the only tool required, making the installation as simple as possible.

This clamp doubtless will appeal to mine operators who are on the lookout for a device of this nature that is absolutely fool-proof.

Commercial Paragraphs

C. H. SHAMEL is engaged in a revision of his book, 'Mining, Mineral and Geological Law,' which is to appear soon. He requests that any readers who may have discovered errors, or have any suggestions for additional topics, communicate with him in care of his publishers, the McGraw-Hill Book Co., 239 West Thirty-ninth street, New York.

THE WATT MINING CAR WHEEL CO., in our issue of March 2, 1912, announced the discontinuance of the Chicago office. It now appears that some persons understood that all branch offices had been abandoned. Such is not the case, as the company still maintains an office in Denver, Colorado, being represented there by Lindrooth, Shubart & Co., and an office in San Francisco, being represented by N. D. Phelps, Sheldon building, and by Carlos Romero in Elzatlan, Jalisco, Mexico.

THE BUCYRUS CO. has taken over the manufacture of the Atlantic type shovel, heretofore built by the American Locomotive Co., and under a license from the patentee, A. W. Robinson, it is the expectation to continue building all of the sizes previously built, and to eventually have a complete line of Atlantic wire-rope shovels, in addition to a complete line of Bucyrus chain type shovels, which the company has been building for thirty years. The building of the Vulcan shovels has been transferred, by the Bucyrus Co., from Toledo, Ohio, to the new plant at Evansville, Indiana. A stock of repair parts for all shovels will be carried at Montreal, New York, San Francisco, Spokane, in addition to a very full supply at the South Milwaukee and Evansville plants. Particular attention will be given to the prompt filling of repair orders, and communications can be addressed either to the company's district sales offices, or direct to the general office at South Milwaukee, Wisconsin.

AFFORESTATION in Korea is being stimulated by the Japanese Government, and in South Pyöng-an province some ten million seedlings will be distributed this year, while coöperation on the part of the natives is stimulated by the offer of numerous small prizes.

RAILROADS were not prosperous in January, according to the returns of the Interstate Railroad Commission. While operating revenues decreased 2.8 per cent, expenses increased 1.3 per cent and taxes 11.7 per cent, with a resultant decrease in net revenues of 15 per cent.

REPORT of the Copper Producers' Association for March, given on another page, shows a decrease of a half million pounds in the stocks available, the daily production during March having averaged 4.03 million pounds, as compared with 4.12 million pounds during February. Electrolytic has ruled at 16 cents per pound recently.

HANDLING mail usually is mentally associated with the postman and his bag, but actually it constitutes in the gross a transportation problem of the first order. This was emphasized last week when the *Tahiti*, due to sail for Melbourne and Sydney, was held in the harbor of San Francisco for three days to await the arrival of seventeen earloads of mail which were being rushed through from Omaha, after having been delayed by floods. A part of the 350 tons of mail in the shipment was destined for Australasia, hence the delay.

LEAD production for 1911 is announced by the United States Geological Survey as having reached 486,975 tons, or an increase of 3.5 per cent as compared with the preceding year. Missouri still holds first place as a producer, with Idaho a good second. Colorado shows a decrease of nearly 17 per cent, while Arizona produced 3450 tons as compared with 858 in 1910. The production from foreign ores showed a considerable decrease, due largely to the disturbed conditions existing in Mexico. The average New York price remained nearly stationary at 4.5 cents during the year.

SETTLEMENT of threatened labor trouble in the bituminous coal mining industry came as welcome news. A long strike would have raised the price of coal and attracted capital to an industry already overdeveloped, at the same time that it would have led either to a long bitter contest waged at heavy expense by the miners or intervention by the Government for political effect. Credit for avoiding these disasters is universally given Mr. John H. Walker, who as a result becomes the dominating figure among the miners and probable successor of Mr. John Mitchell in their affections. The two men are close friends and are not unlike. The miners this year, as in a former crisis, had the whip hand. Now under Mr. Walker's guidance, as then under Mr. Mitchell's, they have chosen the path of moderation, and in both cases it is interesting to note that the interest of the general public was urged as one consideration.

STATE bullion tax returns in Esmeralda county, Nevada, for the quarter ended March 31 amounted to \$31,451, of which the Goldfield Consolidated paid \$25,246, being the tax on 88,381 tons of ore worth \$2,156,108. The preliminary estimate of the production of the Goldfield Consolidated for March is that 30,132 tons of ore of a gross value of \$685,000 was treated at a net profit of \$485,000.

INVESTIGATION of labor conditions in mining by means of a congressional commission is proposed in a bill introduced at Washington by Mr. Martin D. Foster. The text of the measure is printed on another page of this issue. There would seem to be a field for such an investigation, and the proposed mixed commission would be likely to bring out all points of view. That mining, in common with other industries in the United States, has been depressed recently is patent, and a first step to cure is always an accurate diagnosis. Not all the evils of which complaint is made can be remedied, but some may. If, however, any such commission be established definite authority should be given it to inquire into the need of change in the federal mining law. The paralysis of mining, of which much is heard in the West, has certain very direct relations to the need of revision of the law and regulations under which mineral land is located and held.

FUTURE position of the price of silver may be greatly modified by impending changes in the Far East. For many years India and China have been regarded as insatiable consumers of that metal, but recently India has manifested an appetite for gold, having absorbed \$117,000,000 in 1911, as compared with about \$20,000,000 in 1908. The Calcutta government has requested permission to begin coining gold 10-rupee pieces and the demand for gold therefore seems likely to increase rather than decrease. China has for some time been considering the advisability of putting its national coinage upon a gold basis, and the movement toward that end is likely to be accelerated by the foreign loans which will be a necessary part of the process of the reorganization of the government of that country, now under way. The production of silver has steadily increased during the past twenty-five years, while the gold output is a declining one. Many factors enter into the control of the price of silver, but, under the circumstances, it does not seem within the bounds of possibility that it can permanently appreciate within the next few years.

SPORT in the Far North is a serious matter, as is life. A mile-long race on a smooth track to the accompaniment of iced drinks and peanuts does not appeal to men who work through long winter months staking their labor against a rich clean-up in the spring. It is appropriate that the great sporting event of the year is the All-Alaska sweepstakes, a dog-race of 412 miles from Nome to Candle and return. This closed April 8 at 1:30 a.m., and despite the cold and early hour it is said that the whole population of Nome was in the grandstand to welcome Mr. A. A. Allan and the Darling team of malamute dogs when they crossed the line as winners by an hour, with a time of 87 hours and 32 minutes. No small task that, to run over the snow through a blizzard a distance equal to that from San Francisco to Los Angeles, or Chicago to Minneapolis, and all by way of sport. While this fierce race was on in Alaska (it was won by a speed spurt in the last 50 miles), crowds in California were watching the opening games of the base-ball season, and small boys in Chicago were counting off the days till the 'Cubs' and 'Sox' should meet 'Giants' and 'Tigers.' The character of sport varies round the world and with the season, but man must play or he cannot effectively work, and the men who work best have the greatest zest for play.

Government Railroads in Alaska

Washington despatches announce that a conference has been held at the White House between the President and the Secretary of Interior on the one hand, and Messrs. Daniel and Simon Guggenheim on the other, looking toward the sale of the Copper River & Northwestern railroad to the United States Government. We sincerely hope these negotiations may be brought to successful termination. To our way of thinking the importance of a trunk line from the coast to the interior of Alaska transcends all ordinary questions of cost and the building of such a line is a duty the nation owes Alaska. The Copper River route is at least as good as any that could be selected, and is probably the best for the building of a permanent road open the year around. It has the further advantage that many miles of the more difficult part of the line have already been built and that the road can be extended to Fairbanks for a reasonable sum. Furthermore, a fair local traffic is in sight or easily available. The approximate cost of the 197 miles of line already built, including present equipment, was \$16,500,000. The immediate traffic barely pays operating expenses, and for any profit on the transaction the owners must either wait years, or must use the road as a club to obtain mines and other properties along the line at unfair prices. Since no profits are likely for years, all probable or possible losses are bound to be capitalized, and interest charges will form a permanent burden of the country served. As an indication of what that may mean it is interesting to note that the road now has outstanding stock to the amount of \$5,000,000 and bonds to the amount of \$50,000,000; the latter secured by first mortgage on the property and drawing 5 per cent cumulative interest. Probably the bonds have not been distributed, but they at least measure the minimum amount of profit that the promoters of the road will attempt to collect if the line be left in private hands. We believe that neither this nor the use of the road to enforce monopoly is in accord with sound public policy. At the same time capital cannot be expected to undertake hazardous ventures such as this, without reasonable profit, and if the Government is going to restrict such potential profits, it must in fairness assume some of the risk. In years gone by in the Western states the situation was met by giving to the railway companies large grants of public land and, in part, by guaranteeing interest on railway bonds. As a result a network of transportation lines was rapidly built and a series of great commonwealths came into being. As another result, certain venturesome individuals laid the foundations for large private fortunes. With public attention directed especially at the latter fact, it has become impossible to extend the same policy to Alaska. He would be a bold Congressman indeed who would advocate a land grant or a bond guarantee for a Morgan-Guggenheim road in Alaska, and yet, if anything, the risk is greater in railway building in Alaska now than it was in Nebraska when the Union Pacific was projected. Whether roads in the Far North will in the end justify themselves, as did roads in the Far West, is not certain. There are many similarities in the situation, and some important differences. The fact that it is North rather than West does not necessarily signify anything. Alaska, however, needs railways and the nation needs a developed Alaska—a new country as an outlet for surplus population and energy. As a business venture Alaska has paid handsomely, and now that more capital is required to meet legitimate demands for expansion, the nation should not be niggardly.

Whether the Copper River or the Matanuska route is the better is by no means certain; probably railways along both will be needed in time, while either would serve present needs. The Government is accordingly in good

position to negotiate. A fair price should be paid for existing properties, and if the Copper River railroad can be bought at a price based upon cost rather than hopes, completing it would sooner afford the needed transportation to the interior. If the railroad cannot be bought at a reasonable price, then the line from Seward should be extended, but the fact that the nation owes a duty in the case should be recognized, and prompt action is desirable.

The Mascot Mine

Upon two occasions we have criticized the Mascot Copper Company and called attention to the inadequacy of the information given stockholders regarding the property itself, and the financial operations of the company. In our issue of February 3 we called upon the management of the company to give to the public the following information:

1. On the word of a competent and known engineer, after thorough examination, not a mere visit, what are the ore reserves of the property, both as to quantity and grade, and what are the probabilities, if any, of additional reserves being developed?

2. What steps have been taken to determine the proper means of treatment of the ore?

3. What is the financial position of the company, and what will be the distribution of profits, if any, between buyers of the stock now being peddled about, and the promoters?

The announcement has recently been made that a start has been made by the company in the direction of getting the information called for, and the fullest publicity is promised as fast as the data become available. Following the publication of our criticism, Mr. T. N. McCauley, manager of the Mascot Copper Company, employed Mr. Frank L. Sizer as consulting engineer. Mr. Sizer's good work in Montana, and in California, is especially well known, and his familiarity with the type of deposit concerned makes his opinion regarding the Mascot orebodies of particular value. It is understood that Mr. Sizer assumes no responsibility for the financial affairs of the company, but will devote his attention to the technical work at the mine. He is now engaged in making a detailed study of the property. In the meantime we print in full Mr. Sizer's preliminary report and are glad to note that he finds so much to commend. We have never professed to know whether the property was good or bad, contenting ourselves with the statement that an intelligent opinion could not be formed on the basis of the information furnished. We stated that "What is needed is a thorough report upon the property and the company by a disinterested and competent engineer." That the first condition is to be met so satisfactorily emboldens us to hope for an equally frank account of the finances of the company.

Although the corporation was organized in 1907 no detailed financial statement has been given to the public, and in personal conversation the manager, Mr. T. N. McCauley, says frankly that it is not proposed to send out any such statement until the financing of the company has been completed. He states in justification that the stock is not underwritten, and that, the success of the enterprise being dependent upon the public market for the stock, it is not wise to furnish detailed information that would inevitably be accessible to those who might use it to the disadvantage of the stockholders. This raises a question of policy regarding which we are bound to disagree, in that we hold that stockholders in an enterprise are entitled to clear and definite statements regarding all phases of their investment at reasonable intervals, without the expense of a personal visit to headquarters. We hold that no corporation should accept a stockholder's money unless it is pre-

pared to give him full details as to its use. It is regrettably true, however, that many large and old corporations fail to take this view, as well as small and new ones. According to information furnished our representative at the office of the Western Finance Company in San Francisco in 1909, the whole of the stock in the Mascot Copper Company was issued to the Western Finance Company in payment for the properties, and 250,000 out of 1,000,000 shares were then returned to the Mascot Copper Company to be sold for developing and equipping the property. We are now informed that this was an error and that in fact 475,000 shares were returned, leaving the Western Finance Company the holder of 52½ per cent of the stock of the Mascot company. For this there was given to the latter 35 claims to which title was complete and 3 upon which \$50,000 remained to be paid. It is stated that up to that date \$200,000 had been expended on the property and that since the transfer and up to March 1, 1912, about \$400,000 additional has been expended. So far as we are aware this is the most complete financial statement yet made public, and while it leaves something to be desired, it indicates a larger participation in profits by minor stockholders than did the statement formerly given us and materially modifies the force of our criticism.

We confess frankly to a prejudice against the company because of the theatrical methods of promotion employed, but a good dog should not be condemned because he has a bad name, and we are sincerely glad that evidence indicates the probability of the Mascot company having the first essential of a successful mining company—a good mine.

Cooks and the Panama Broth

Truth of the epigram, 'many men, many minds,' is well exhibited by the present diversity of opinion regarding the maintenance and operation of the Panama canal. A recent writer in the *Saturday Evening Post* has gathered together, in an amusing way, authoritative and equally convincing opinions supporting both the negative and affirmative view of every question that has been broached regarding that great waterway. It is reasonably clear that no one knows anything about the matter and that opinions are based upon the slightest substratum of information. To the thoughtful engineer this does not appear remarkable, being rather what might *a priori* be expected. Americans have had no experience in the operation of a canal of even a fraction of the size of that at Panama, and in regard to the future development of trade through the canal, an accurate estimate can, in the present absence of information, no more be made than can the probable achievements of an unborn child be prophesied. About the fixing of the proper toll rate discussion chiefly centres; much of it but little to the point. The maximum rate should immediately be fixed, so that shipping companies can make plans for the future, but there is no necessity for fixing the exact rate, or indeed for imposing any toll, until precise information is available to guide action. What should be done now is to announce a maximum rate, that will not be exceeded, and provide that no toll shall be imposed before the end of 1916 or later. Millions have been spent upon a canal which is to serve future generations; whether any income be derived from it for the first few years is a matter of the least importance. What is desirable is to develop traffic through the canal as rapidly as possible, and if no toll were charged for even five years and then the proper rate imposed, it is unquestionable that the total return to the end of 1950 will be greater than if a series of readjustments are made during that period. The canal has been constructed quickly and well by capable men using intelligent methods; now let it be operated by intelligent methods.

Birth of the American Mining Act—I

By H. W. MACFARREN

DISCOVERY OF GOLD

When gold was found by John Marshall and his workmen January 19, 1848, no thought was probably more distant from their minds than that of mining rights and the ownership of the precious grains lying in the creek-bed sands. Fourteen days later, February 2, 1848, the treaty of Guadalupe Hidalgo was signed, and the right of conquest begun with the hoisting of the American flag at Monterey on July 7, 1846, was completed. Colonel Mason, then military governor of California, visited the gold diggings in June following Marshall's discovery. They at that time were populated by a few thousand people from the surrounding parts of California, a population that rapidly grew and spread day by day. Colonel Mason, who had previously declared the Mexican mining laws to be repealed, was impressed, and reported: "It was a matter of serious reflection with me how I could secure to the Government certain rents or fees for the privilege of securing this gold; but considering the large extent of country, the character of the people engaged, and the small scattered forces at my command, I resolved not to interfere, but to permit all to work freely, unless broils and crime call for interference."

As the Argonauts poured across the summits of the Sierras and through the Golden Gate to occupy the foothill ravines of the gold belt, California must have meant to them a land so boundless in extent, so removed from their heretofore world, so unknown and unpopulated, that they would be free to mine its rich treasure without hindrance. The sobering thought may have come to them later that they were trespassers upon the public domain, appropriating it and its mineral content without the sanction of any law, in fact, against the express intent of the law. For this they probably found solace in the thought that it was the most expedient thing for them to do, and that the national Government was under a moral obligation to make provisions for them to mine. As time passed and no provision was made, the miners came to consider that the national Government acquiesced in their actions and would protect them therein. This idea has permeated all of our public-land history—that the Government is a protective and benevolent institution, a wise father who will care for his children that have gone forth into the wilderness to carve out fame and fortune for themselves. Settler, preëmtor, homesteader, and miner have clung to this principle with simple-minded faith, and evil will be the day in which it is forgotten or abandoned.

Though the miners gave no heed to the ownership in fee of the land, they found it necessary to take steps that each might have an equal chance, and in this way arose the miner's customs and regulations. The details and history of these are not a part of the present subject. It is my purpose merely to show the conditions under which was passed the first and original mining act of 1866 relating to lode claims, the second act of 1870 relating to placer claims, and the third and final act of 1872—the present mining law—superseding and perfecting the acts of 1866 and 1870.

FIRST LAND LAWS

The preëmption act of September 4, 1841, to enable a settler upon public land to obtain 160 acres at \$1.25 per acre in deferred payments, contained the clause, "and no lands on which are situated any known salines or mines, shall be liable to entry under and by virtue of the provisions of this act." This and similar previous reservations of mineral lands established the organic principle that mineral land was not to be obtained under agricultural-land laws, but no law for the disposal of mineral land and mines was provided. Consequently, when gold was discovered in California there was no law by which the mines or mineral land could be taken up. This condition was intensified by the

act of March 3, 1853, providing that no preëmption right could be obtained on mineral land; also by the refusal of the Land Department to have surveys made in the mineral-land districts. In 1850 California was admitted into the Union and in the following year legalized the district rules and regulations of the miners by an act reading: "In actions respecting mining claims, proof shall be admitted of the customs, usages, or regulations established and in force at the bar or diggings embraced in such claims; and such customs, usages, or regulations when not in conflict with the constitution and laws of this state, shall govern the decision of the action." The Federal courts followed the rule laid down by the state of California for the guidance of its courts, while the same manner of procedure was followed in the later mining states and territories. This makes clear the working of the early mining law. There was no fee title or real ownership to the land known to contain mineral. It remained in possession of the national Government, for it was reserved from the operations of the agricultural-land laws and there were no mineral-land laws. The miner was simply holding the land by right of possession, by 'possessory right.' He was protected by no national statute, he had no vested right, he could be evicted from his possessions at any time Congress might pass an act for that purpose. The miners met in mass-meetings in the different districts and adopted rules and regulations regarding the manner of taking up and holding mining claims and mineral land. When disputes arose over mining claims, a court of local miners was held, or the matter was taken into the recognized local courts after these were formed. In these courts the matter was decided upon the mining customs and regulations of the district and the principles of equity.

MINERS REGULATIONS

The miners' rules and customs varied greatly, notwithstanding that they had the same general tenure. J. Ross Browne, in his official report of 1866 upon the 'Mineral Resources West of the Rocky Mountains,' estimated that there were not less than 500 mining districts in California, 200 in Nevada, and 100 each in Arizona, Idaho, and Oregon, each with its set of written regulations. John S. Hittell, in his 'Baneroft's Handbook of Mining for the Pacific States,' published in 1861, gives the regulations of many districts. From these we shall select two brief representative sets: Tuolumne county in California and Virginia mining district in Carson county, Nevada. The quartz miners of Tuolumne county adopted the following code of regulations in 1858, and they are still in force:

Art. 1. The jurisdiction of the following laws shall extend over and govern all quartz-mining property within Tuolumne county.

Art. 2. Each proprietor or locator of a quartz claim shall be entitled to 150 ft. in length of the vein, including all its dips and angles; also 150 ft. on each side of said vein, together with the right of way on either side of said vein, to run tunnels and drifts any distance that may be necessary in order to work said vein. Provided, that the right to 150 ft. granted on each side of the vein, shall not be deemed to conflict with or detract from the right of any subsequent locator, who may discover a vein outside of said 150 ft., from following his vein through said ground.

Art. 3. The original discoverer of a vein shall be entitled to hold 300 ft. in length on said vein, by virtue of discovery.

Art. 4. No man shall, by virtue of pre-emption, be entitled to hold more than one claim on the same vein, except as provided in article three.

Art. 5. All quartz claims hereafter taken up or located shall be plainly marked by notices posted, containing the claimants' names and number of feet claimed.

Art. 6. The parties locating a quartz claim shall put at least one full day's work on said vein in every 30 days, in order to hold the same. A day's work shall be eight hours' labor. Provided, however, that the sum of \$100

expended on said claim, shall hold the same for six months from date of its expenditure.

Art. 7. Any individual, company, or companies erecting machinery for working quartz shall, by virtue of said machinery, hold the vein or veins belonging to said individual, company, or companies.

Art. 8. These laws shall be in full force and effect from and after the first day of September, A. D. 1858.

At a meeting of the miners of Virginia district, held at Virginia City, Nevada, September 14, 1859, the following rules were adopted for the government of the mines of said district.

Art. 1. All quartz claims hereafter located shall be 200 ft. on the lead, including all its dips and angles.

Art. 2. All discoverers of new quartz veins shall be entitled to an additional claim for discovery.

Art. 3. All claims shall be designated by stakes and notices at each corner.

Art. 4. All quartz claims shall be worked to the amount of \$10 or three days' work per month to each claim, and the owner can work to the amount of \$40 as soon after the location of the claim as he may elect; which amount being worked, shall exempt him from working on said claim for six months thereafter.

Art. 5. All quartz claims shall be designated and known by a name and in sections.

Art. 6. All claims shall be properly recorded within ten days from time of location.

Art. 7. All claims recorded in the Gold Hill record and lying in the Virginia district, shall be recorded free of charge in the record of Virginia district, upon the presentation of a certificate from the recorder of Gold Hill district, certifying that said claims have been duly recorded in said district; and said claims shall be recorded within 30 days after the passage of this article.

Art. 9. Surface and hill claims shall be 100 ft. square, and designated by stakes and notices at each corner.

Art. 10. All ravine and gulch claims shall be 100 ft. in length, and in width extend from bank to bank, and be designated by a stake and notice at each end.

Art. 11. All claims shall be worked within 10 days after water can be had sufficient to work said claims.

Art. 12. All ravine, gulch, and surface claims shall be recorded within 10 days after location.

Art. 13. All claims not worked according to the laws of this district, shall be forfeited and subject to relocation.

Art. 14. There shall be a recorder elected, to hold his office for term of 12 months, who shall be entitled to the sum of 50c. for each claim located and recorded.

Art. 15. The recorder shall keep a book with all the laws of this district written therein, which shall at all times be subject to the inspection of the miners of said district; and he is furthermore required to post in two conspicuous places a copy of the laws of said district.

Most of the mining states and territories passed state mining acts. The Arizona statute of 1865 contained 53 sections, and was a long and formidable document, drawn up with much legal ability and mining experience.

THE FREMONT BILL

On September 14, 1850, John C. Fremont, senator from the newly admitted state of California, introduced into the Senate 'a bill to make temporary provision for the working and discovery of gold mines and placers in California, and for preserving order in the gold mining districts.' On September 24 and 25 it was debated at considerable length and amended. The bill was in the nature of police regulations levying a tax or ground rent upon the miners. As amended it provided for six Government agents who were to travel about the mining districts. They were to issue annual permits to work placers at the rate of one dollar per month for a placer 30 ft. square, and \$50 per month for a placer of the maximum size of 210 ft. square or one acre. The permits were to be marked upon the ground by the Government agents. No permits were to be issued to aliens, except to those of good character from Europe. Such men as Benton and Seward declared themselves in favor of not attempting to derive revenue from the gold mines, but nevertheless helped to pass the bill. It was passed by the Senate on September 25, 1850, and was brought up in the House of Representatives, but was not considered and thereby failed to become a law.

Before any further legislation was proposed, the miners rules and customs had developed into a serviceable instrument of law, especially under its recognition by the legislature and statutes of the state of California. Congress

now wisely concluded that it was too little informed on the subject to make any suitable laws, and made no further attempts at legislation for the gold mines. This state of affairs continued until 1864, when, in casting about for means to pay off the enormous national debt incurred by the Civil War, it was proposed to sell the mineral lands of the West. George W. Julian, of Indiana, introduced into the House of Representatives on February 2, 1865, a bill to provide for selling the mines, and made an extended speech upon it. On December 5 of the same year, John Sherman, senator from Ohio, presented a bill of the same purport to the Senate. Similar bills had been and were being proposed, and Western miners were commencing to realize that they were dangerously near the parting of the ways; their laws and the assumed rights under which they had grown and prospered were about to be swept away, their possessions were about to be sold over their heads, and they were to be driven out as mere trespassers. Indignation meetings were held and memorials were prepared by civic bodies and state legislatures protecting against such unthought-of action. It is only fair to state that the proposed bills did not intend to take away bodily the mines from those who were in possession of them. The possessors were to have a preferred right to acquire them. But Mr. Sherman's bill proposed that the minimum price should be \$50 per acre. All provided that as high a price as possible should be secured through public auction, and the land should be sold in blocks similar to agricultural land. They sounded the death knell of free mining as it was then understood.

PROPOSAL TO SELL MINERAL LAND

One of the senators from California was John Conness, who had introduced a bill into the Senate in 1864 to permit miners to locate and purchase mineral land. Upon the admission of Nevada into the Union in 1865, he presented to the Senate the credentials of William M. Stewart as one of the senators to represent the new state. These two men were the fathers of the American mining acts. In this they responded to the appeals of their constituencies and the Western miners. Mr. Conness brought to bear on the subject his knowledge of mining in California and his experience with his first bill. Mr. Stewart came with full knowledge of the conditions then existing on the Comstock, where, through the fabulous richness of the lodes and the insecurity of possessory titles, the business of producing and continuing litigation had been perfected to a state perhaps higher than it ever reached before or since. He was, in addition to being a lawyer, a miner who had attained wealth, only to have it swept away by unforeseen accident, by flood. A bill was carefully framed by the combined efforts of these two men as members of the Senatorial Committees on Mines and Mining and on Public Lands, of the Treasury Department, and John Sherman as representing the contingent which was seeking to lighten the load of the national debt, and of the Land Department as representing the office in charge of the public lands which had repeatedly urged that some disposition of the mineral lands should be made to enable agricultural land in mineral-land areas to be segregated. This bill was to become the first mining act, and by the extension of the act of 1870 and the amplification of the act of 1872, to become our present mining act. Messrs. Stewart and Conness dominated in its framing, and it was virtually their handiwork. John Sherman introduced the bill into the Senate on April 9, 1866, as Senate bill No. 257, with the title of 'A bill to regulate the occupancy of mineral lands and extend the right of preemption thereto.' Its purpose was to recognize and to confirm for all time to come the possessory rights of the miners, to confirm water and ditch rights, to enable lode or quartz claims to be purchased from the Government, and to enable agricultural land in mineral-land areas to be segregated and patented. On June 18 it was discussed by the Senate as a committee of the whole, nearly the entire day being given to discussing it. It was again considered at length on June 28. Mr. Stewart opened the discussion on the floor of the Senate

with an able defense of the rights of the miners and the necessity of the act, saying in part:

MR. STEWART'S SPEECH

Upon the discovery of gold in California in 1848, a large emigration of young men immediately rushed to the modern Ophir. These people, numbering in a few months hundreds of thousands, on arriving at their future home found no laws governing the possession and occupation of mines but the common law of right, which Americans alone are educated to administer. They were forced by the very necessity of the case to make laws for themselves. The reason and justice of the laws they formed challenged the admiration of all who investigate them. Each mining district, in an area extending over not less than 50,000 square miles, formed its own rules and adopted its own customs. The similarity of these rules and customs throughout the entire mining region was so great as to attain the beneficial results of well digested, general laws. These regulations were thoroughly democratic in their character, guarding against every form of monopoly, and requiring continued work and occupation in good faith to constitute a valid possession.

After the admission of California as a state in September, 1850, Mr. Fremont, then senator from that state, introduced a bill, the purpose of which was to establish police regulations in the mines. It imposed a small tax upon the miners to defray the expenses of the system. Many senators, when the bill came up for consideration, expressed the opinion that the mines ought to be sold or some means devised by which a direct revenue might be obtained from that source. Various amendments were offered to effect these purposes. But Mr. Benton took a leading part in the discussion, and contended throughout that good policy required that the mines should remain free and open to exploration and development. Mr. Seward sustained Mr. Benton. The arguments of senators in favor of free mining finally prevailed, and all amendments looking to sale or direct revenue were voted down, and the bill finally passed the Senate, without material amendment, in its original form, but failed in the House for the want of time to consider it. This solemn declaration on the part of the Senate in favor of a just and liberal policy to the miners was hailed by them as a practical recognition of their possessory rights, and greatly encouraged and stimulated mining enterprise and laid the foundation for a system of local government now in force over a vast region of country inhabited by nearly a million men.

LEGISLATION BY CALIFORNIA

The legislature of California, at the following session, in 1851, had under consideration the subject of legislating for the mines; and after full and careful investigation wisely concluded to declare that the rules and regulations of the miners themselves might be offered in evidence in all controversies respecting mining claims, and when not in conflict with the constitution or laws of the state or the United States, should govern the decision of the action. A series of wise judicial decisions moulded these regulations and customs into a comprehensive system of common law, embracing not only mining law (properly speaking), but also regulating the use of water for mining purposes. The same system has spread over all the interior states and territories where mines have been found, as far east as the Missouri river. The miner's law is a part of the miner's nature. He made it. It is his bantling, and he loves it, trusts it, and obeys it. He has given the honest toil of his life to discover wealth, which, when found, is protected by no higher law than that enacted by himself under the implied sanction of a just and generous government. Miners as a community devote three-fourths of their aggregate labor to exploration, and consequently, and ever will remain, poor, while individuals amass large fortunes, and the treasury of the world is augmented and replenished.

Senators who have not given this subject special attention can hardly realize the wonderful results of this system of free mining. The incentive to the pioneer held out by the reward of a gold and silver mine, if he can find one, is magical upon the sanguine temperament of the prospector. For near a quarter of a century a race of men, constituting a majority by far of all the miners of the West, patient of toil, hopeful of success, deprived of the associations of home and family, have devoted themselves, with untiring energy, to making deep shafts, running tunnels thousands of feet into solid granite, traversing deserts, climbing mountains, and enduring every conceivable hardship and privation, exploring for mines, all predicated upon the idea that no change would be made in this system that would deprive them of their hard-earned treasure. Some of these have found valuable mines and a sure prospect of wealth and comfort when the appliances of capital and machinery shall be brought to their aid. Others have received no compensation but anticipation, no reward but hope.

WORK OF THE PROSPECTOR

While these people have done little for themselves, they have done valuable services for this Government. They have enhanced the value of the property of the nation near one hundred per cent, as I shall hereafter show, and they have converted that vast unknown region, extending from British Columbia on the north to Mexico on the south, and from the eastern slope of the Rocky Mountains to the western decline of the Sierra Nevada, into the great gold and silver fields of the United States, surpassing in richness and extent the mines of any other nation on the globe. I assert, and no one familiar with the subject will question the fact, that the sand plains, alkaline deserts, and dreary mountains of rock and sagebrush of the great interior would have been as worthless today as when they were marked by geographers as the 'great American desert' but for this system of free mining fostered by our neglect and matured and perfected by our generous inaction. No miner has ever doubted the continued good faith of the Government, but has put his trust in its justice and liberality, traversing mountain and desert as incessantly and as hopefully as the farmer of the West has ploughed his field. What he now occupies he has discovered and added to the wealth of the nation.

This faith of the Government (promised, as it were, by the actions of this Senate sixteen years ago) not only inspired enterprise and led to discoveries the magnitude and importance of which cannot be overestimated, but in the time of the severest trials of the Union, no people were more loyal than the miners. They lost no opportunity to enlist in the armies or contribute to the support of the Government. Their liberal donation to the sanitary fund was but a slight manifestation of their deep love of the Union and sympathy for its suffering heroes. The little town in which I reside (Virginia City) contributed in gold coin over \$112,000, being at the time about thirty dollars to each voting inhabitant, and a like liberality was displayed by the whole Coast. The people are truly grateful to a generous Government, and time seems to have strengthened the tender regard they feel for their native land and their early homes, but they look with jealous eyes upon every proposition for the sale of the mines which they have discovered and made valuable. Any public man who advocates it, with whatever motive, is likely to be condemned and discarded as an unfaithful servant. The reason is obvious. It is their all, secured through long years of incessant toil and privation, and they associate any sale with a sale at auction where capital is to compete with poverty; fraud and integrity with truth and honesty. It is not because they do not desire a fee-simple title, for this they would prize above all else; but most of them are poor and unable to purchase in competition with capitalists and speculators, which the adoption of any plan heretofore proposed would compel them to do; and for these reasons the opposition to the sale of the mineral lands has been unanimous in the mining states and territories.

OCCURRENCE OF VEINS

To extend the preëmption system, applicable to agricultural lands, to mines is absolutely impossible and absurd. Nature does not deposit the precious metals in rectangular forms descending between perpendicular lines into the earth, but in veins or lodes varying from one to three hundred feet in width, dipping from a perpendicular from one to eighty degrees, and coursing through mountains and ravines at nearly every point of the compass. In exploring for vein mines it is a vein or lode that is discovered, not a quarter section of land marked by surveyed boundaries. In working a vein more or less land is required, depending upon its size, course, dip, and a great variety of other circumstances not possible to provide for in passing general laws. Sometimes these veins are found in groups, within a few feet of each other, and dipping into the earth at an angle of from 30° to 50°, as at Freiberg in Saxony, or Austin in Nevada. In such a case a person buying a single acre in a rectangular form would have several mines at the surface and none at 500 or 1000 ft. in depth. With such a division of a mine, one owning at the surface, another at a greater depth, neither would be justified in expending money in costly machinery, deep shafts, and long tunnels for working the same. Nor will it do to sell the land in advance of discovery, for this would stop explorations and practically limit our mining wealth to the mines already found, for no one would prospect with much energy upon the land of another, and land speculators never find mines. The mineral lands must remain open and free to exploration and development, and while this policy is pursued our mineral resources are inexhaustible. There is room enough for every prospector who wishes to try his luck in hunting for new mines for a thousand years of exploration, and yet there will be plenty of mines undiscovered. It would be a national calamity to adopt any system that would close the region to the prospector.

The question then presents itself, how shall the Govern-

ment give title, so important for present prosperity, and avoid these intolerable evils? I answer, there is but one mode, and that is to assure the title to those who now or hereafter may occupy according to local rules suited to the character of the mines and circumstances of each mining district. The importance of legislation of this kind is daily increasing by the agitation of the subject, by the introduction of bills looking to what the miners regard as a general system of confiscation, destroying all confidence in mining titles, and by the absolute necessity of some system guaranteeing to capitalists security for their investment. The system proposed by this report may be improved by experience, but your committee would apprehend evil consequences from any material change of the plan at this time. It continues the system of free mining, holding the mineral lands open to exploration and occupation subject to legislation by Congress and local rules. It recognizes the obligations of the Government to respect private rights which have grown up under its tacit consent and approval. It is also in harmony with the rules of property, as understood by a million men, with the legislation of nine states and territories, with a course of judicial decisions extending over near a quarter of a century and finally ratified and confirmed by the Supreme Court of the United States. In short, it is in harmony with justice and good policy.

The plan further proposes to allow the miners who have and who may hereafter occupy and improve mines in good faith, and according to local rules, to purchase at the rate of \$5 per acre and receive a patent therefore in such a form as shall grant the mine with its dips, spurs, and angles to any depth, with such a reasonable amount of surface as the miners shall determine by local rules to be necessary for the working of the same. It also provides, in the case of dispute as to the right of possession, for the determination of that question in the local courts where the miners' laws are understood and fairly administered. It makes the public surveys conform to nature, not nature to the surveys. It furnishes the means to actual settlers of acquiring title to their homesteads by segregating the agricultural from the mineral lands, and confirms the rights to the use of water and the rights of way for ditches as established by local law and the decisions of the courts. In short, it proposes no new system, but sanctions, regulates, and confirms a system to which the people are devotedly attached, and removes a cloud of doubt and uncertainty which recently has depressed and retarded the growth and prosperity of our mining communities. In my opinion this bill will furnish homes to thousands of families, give stability to mining titles, invite capital, and greatly increase the production of the precious metals.

DEVELOPMENT OF MINERAL LANDS

The primary conditions upon which the development of our national wealth depend are: (1) transportation; (2) a scientific knowledge of mining; (3) security of titles; and (4) abundance of capital. The first question is involved in the speedy completion of the Pacific railroad. We need mining colleges in the mining districts where the youth of America may study the science of mining with the laboratory of nature before him as a guide, and where theory and practice may be combined. We want a law of the character of the bill under consideration to establish and secure mining titles. While these are in doubt, a feeling of insecurity will paralyze all our efforts. Let a just, liberal, and definite policy be adopted toward the miners. Add to their possession the absolute right of property, and you will have laid a solid foundation for large and increasing yields. The feeling of security and independence produced by the right of property in the soil is the real foundation of our stability and prosperity as a people. A nation of freeholders is a nation of sovereigns, but a nation of tenants is a nation of slaves. Let not our free system of mining be degraded into miserable monopolies or disastrous confusion, but let it be confirmed, enlarged, and perfected, and the great national bank of redemption in the West will never refuse specie payment.

(To be Continued)

MUREA, a small island 100 miles east of British Papua, produces a considerable amount of gold, the output for December last being estimated at \$30,000. It is reported that ore containing as much as 20 oz. per ton is found, a modern mill which has recently been erected there commonly treats 10 to 15-oz. ore. A few miles south is the island of Misima, having an area of 7 sq. mi., where a large mill has been erected and good returns are confidently expected. A local dredging company has been formed and expects to reap large returns from working the rivers of the northern portion. A neighboring island, Sudest, is reported to have, next to the Klondike, yielded the largest output of gold per square mile of alluvial working.

A Bill to Create a Commission on Mining

*Be it enacted by the Senate and House of Representatives of the United States of America in Congress assembled, that a commission is hereby created, to be called the Commission on Mining Industry. Said commission shall be composed of eleven persons, to be appointed as follows: two members of the Senate (including the chairman of the Committee on Mines and Mining and one member to be appointed by the President of the Senate), two members of the House of Representatives (including the chairman of the Committee on Mines and Mining and one member to be appointed by the Speaker of the House), two representatives of mine operators, two representatives of miners, two mining engineers, and one representative of the Bureau of Mines, to be appointed by the President of the United States.

SEC. 2. That the members of this commission shall be paid actual traveling and other necessary expenses, and in addition a compensation of ten dollars per diem shall be paid those who are not officials of the Government during their service on said commission and while engaged on the work of the commission and while going to or returning from such work. The commission is authorized, as a whole or by subcommittee of the commission duly appointed, to hold sittings and public hearings anywhere in the United States, to send for persons and papers, to administer oaths, to summon and compel the attendance of witnesses and to compel testimony, and to employ such secretaries, experts, stenographers, and other assistants as shall be necessary to carry out the purposes for which such commission is created, and to authorize its members or its employees to travel in or outside of the United States on the business of the commission.

SEC. 3. That said commission may report to the Congress its findings and recommendations from time to time, and shall make a final report not later than two years after the date of the approval of this Act, at which time the term of this commission shall expire unless it shall previously have made final report, and in the latter case the term of the commission shall expire with the making of its final report, and the commission shall make at least one report to the Congress within the first year of its appointment and final report at the end of two years.

SEC. 4. That the commission shall inquire into the general condition of labor employed in the mining industry of the United States, and especially as to the safety of mining and the methods of more efficient mining and the conservation of the mineral products of the United States; into existing relations between employers and employees; into the growth of associations of employers and of wage-earners and the effect of such associations upon the relations between employers and employees; into any methods which have been tried in any State or in foreign countries for maintaining mutually satisfactory relations between employees and employers; into methods for avoiding or adjusting labor disputes through peaceful and conciliatory mediation and negotiations; and into the scope and methods and resources of existing bureaus of labor and of mines, and into possible ways of increasing their usefulness so far as the mining industry is concerned. The commission shall seek to discover and to point out the underlying causes of dissatisfaction in the mining situation.

OPERATING costs at the East Rand Proprietary have risen from 14s. 9d. in January 1911 to 19s. 4d. in December. This is due, according to a recent report by H. Ross Skinner, the superintending engineer, to an alteration in the basis of calculating tonnages, decrease in tonnage milled, revision of the classification of development work, the exclusion from tonnage milled of such items as 'accumulated slime' and the increase of fixed charges due to curtailment of development.

*A bill (H. R., 22342) introduced in the House of Representatives on March 26 by M. D. Foster, chairman of the Committee on Mines and Mining.

Elevating Ten-Cent Gravel at a Profit

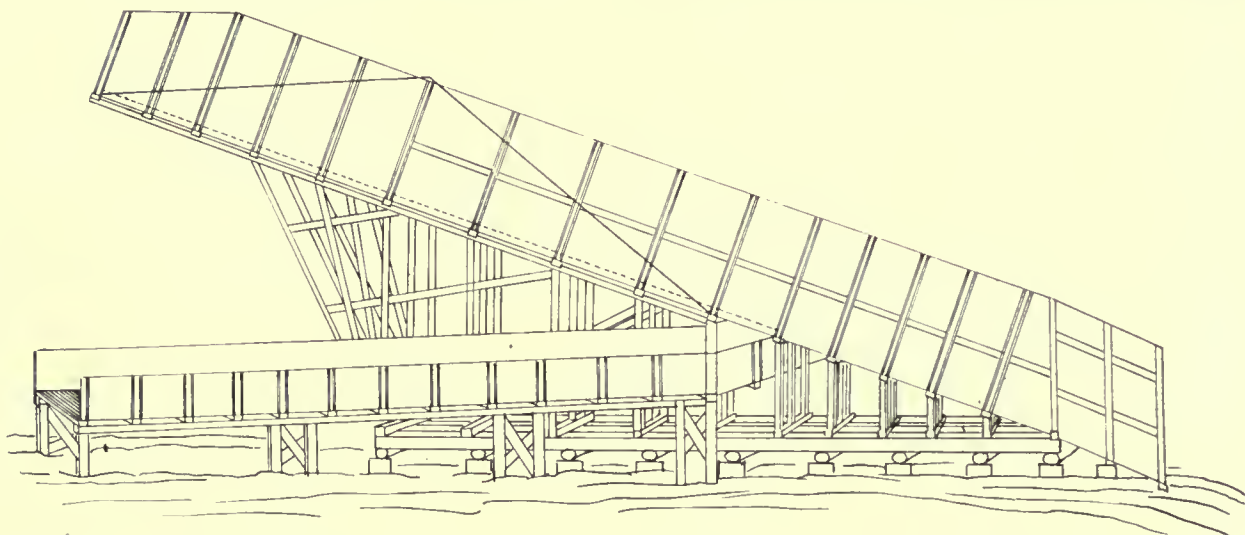

By C. S. HALEY

California, from the very first discovery of gold, in 1848, has well deserved the title of the Golden State. The early production from surface deposits of gravel, when individual prospectors poured a golden stream into the coffers of the nation from the pan, the rocker, the long-tom, and the ground-sluice, was later given a longer lease of life by the adoption of high-pressure giants, which uncovered the deeper and, in many cases, richer gravels. Coincident with the rattle of the boulders through the sluices came the development of lode mining, and the roar of many hundred stamps along the Mother Lode evidenced the healthy condition of a flourishing industry.

Later, when the agricultural interests began to predominate, and the ravages of the mud-swollen Sacramento forced the curtailing of the hydraulic output, it seemed as though, when the richer quartz veins were exhausted, with them the golden flood would cease. In fact, in the later eighties and early nineties, a decline in production set in which was so obvious that on all sides it was freely predicted that the

ing are the broader lower-grade river bars which are, in the main, very slightly above the beds of the present rivers.

Every experienced miner knows that in handling low-grade gravel capacity is the main essential, in so far as it is consistent with saving the gold. In cutting down operating expenses and reducing overhead cost per cubic yard, lies the secret of success with gravels of this type. It is equally evident that capacity is limited by facility in the disposal of tailing, other conditions being favorable. This, in the past, has been the great advantage of the dredge over the hydraulic giant for the low river bars. In spite of the large initial cost and the consequent overhead expense, the increase in capacity has more than made up. However, it is my purpose to show, from facts in my own experience, first, that by the employment of very simple means, the giant can compete with the dredge for the banks of more moderate depth (say up to 50 ft.); and, second, that on bars of this type which are now closed by the *débris* law, the hydraulic giant can be operated at its best capacity, where the slightest

SIDE ELEVATION OF ELEVATOR. THE DOTTED LINE INDICATES THE POSITION OF THE GRIZZLY.

dawn of the new century would find the state shorn of the title which was her early pride. By this time, the hydraulic division of the industry was practically confined to the northern portion of the state, whose streams, tributary to the Klamath and the Pacific, were unaffected by the *débris* law. In the eastern and central portion, such gravels as were worked were mainly handled by drifting, as in the ancient channels of the Sierras, whose gravels were mostly capped by prehistoric lava flows.

But the beginning of the new century saw the development of a new industry, which was destined to restore the production to respectable proportions. The utilization of bucket dredges opened a new and hitherto untried field to the miner. The broad stream beds of the Yuba, the Feather, and other tributaries of the Sacramento became a prolific source of wealth, and the waning production soon began to advance by leaps which offset the decline of quartz mining, until in 1910 the dredges produced more than 38% of the entire gold output of the state.

Naturally, the marked success of the gold dredges attracted the attention of gravel miners all over the coast. In the northern counties of Siskiyou, Trinity, and Humboldt, as well as Del Norte, the hydraulic mining industry has been for some years on the wane. The richer bars, with good 'dumps,' or storage space for the disposal of tailing, have been gradually worked out, and aside from those which are so difficult of access with water that their extent does not justify the necessary expenditure, the only gravels remain-

impounding room is available at the start, without disturbing the well-earned repose of any farmer in the Sacramento valley.

The dredge has its limitations, and this fact is nowhere more clearly evidenced than in operation on the river bars of northern California. The gravels of the Scott, the Trinity, the Salmon, and the Klamath rivers are for the most part, on account of geological and topographical reasons, of a different type than those of the great dredging fields of the east-central portion of the state, and in most cases the distribution of the gold is different. Ideal dredging ground is free from large boulders, has fairly smooth soft bedrock, and, more important than all else, the gold is evenly distributed through the gravel, and does not lie chiefly on the bedrock. Besides this, the bars must be of sufficient extent to justify the initial expense of installation, with its subsequent yardage cost in depreciation and interest.

To these conditions the productive low-grade gravels of Yuba, Butte, and Sacramento counties very largely conform. On the other hand, the bars of the more mountainous northern streams, with their greater grades, present, in the main, conditions decidedly the reverse. The bars average from twenty to one hundred acres in extent, although they may be in frequent succession on opposite sides of the same river. The ground is decidedly heavy, and boulders weighing from one to five tons are common. And, most important of all, in many cases the gold which goes to make up even the low yardage average, lies chiefly, or in very

large part, on or near the bedrock. This necessitates, of course, exposure and careful cleaning of the bottom of the channel. In case of a hard uneven bedrock, this is something which would be beyond the powers of the best dredge made. Failure to understand these conditions has 'given a black eye' to dredge operation in many instances, where a careful investigation of the ground in the first place should have precluded its adoption.

However, this does not imply that dredge installation upon these rivers is a waste of money in all cases. In the valley of the Scott, for instance, where the river has a more gentle grade and has formed large bars, there is no question but what there is a considerable quantity of ground available for dredging purposes. It is not the purpose of this article to deal with ground of this type, but with ground which from its nature can better be handled by an adaptation of the hydraulic process to its needs.

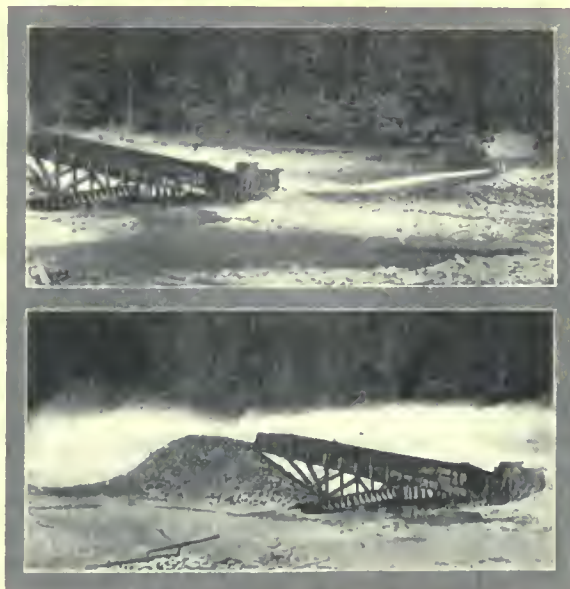

Obviously, in bars of the type described, available for hydraulic installation and yet too low on the river bed for the easy removal of tailing, some method of elevation must be adopted which will stack the tailing fast enough to allow a tremendous yardage during the water season. I have discussed, very briefly, in a former article in the *Mining and Scientific Press*, some of the methods in use in northern California, and have since had occasion for a more or less extended study of one of these methods which has only recently been put in general practice, and which seems likely to furnish a solution for the problem of handling profitably the low-grade, poor dump bars of rivers of this type, as well as the problems of operating some of the richer gravels of the Sierras without running afoul of the debris law. In fact, the low yardage cost possible by an application of this method comes dangerously near to competition with the dredging industry in its own chosen field.

The elevating system described was developed several years ago and patented by an operator on Coyote creek, in Josephine county, Oregon. Installations have been made as far distant as Alaska and South America, but it is only of late years that it has begun to attract attention in the land of its birth. The principle of the machine is very simple. It consists of an approach, or apron, running from the bedrock up into the elevator, and the main elevator, which is an inclined trough about 8 ft. wide, with sides tapering from 12 ft. high at the bottom to 6 ft. at the upper end. The pitch of the incline is about 17° , and the total length varies from 80 to 100 ft. Besides the apron, which is about 10 ft. long, the first 20 ft. of the incline is solid, and lined with $\frac{3}{8}$ -in. steel, as are the sides. Above this, and extending clear to the top of the incline, are grizzly-bars made of $2\frac{1}{2}$ by 6-in. timbers covered with 3-in. steel $\frac{3}{8}$ in. thick. Beneath the grizzly-bars is the bottom, sloping down to the sluice-box, which runs out directly beneath the grizzly-bars, and is trussed for the first 10 ft. to the framework of the elevator. The bottom beneath the grizzly is lined with No. 14 steel, as is the sluice-box. The bottom of the solid portion of the incline, beneath the lining, consists of double $1\frac{1}{4}$ -in. boards; that below the grizzly of a single thickness of the same. The sides of the elevator are double boarded. The space below the line of the grizzly is about 16 in. deep, and the grizzly-bars are about $2\frac{1}{2}$ in. apart. Supporting the bars are 2 by 8-in. stringers, running from the sluice-box up to the top of the grizzly. The rifles in the sluice-box, which is made in sections and built out from the elevator, are made of 2 by 4-in. scantling, covered with $\frac{1}{4}$ -in. steel strips, about 4 ft. long, and set crossways in the box about 2 in. apart. Larger and heavier rifles are set lengthways at intervals. As nothing but the fine goes through the sluice, these rifles are amply durable. The construction of the framework, together with details of bracing and supports, is shown in the drawing. Braces may be made of 6 by 6-in. or even heavier timber, but if it is convenient to procure them, iron tie-rods for tension members make a lighter construction. Some improvements in detail of design may also be suggested by experience, but the drawing shows the construction of an elevator now in actual use at the Red Hill mine, the property of the Michigan Salmon Mining Co. at

Forks of Salmon, California. The illustrations show the same machine.

In operating with this elevator, the chief loss in dead work consists in moving the machine, as it is somewhat cumbersome. Also, of course, a bedrock cut and drain-boxes are necessary to drain the channel. However, the use of a derrick is not necessary, as boulders up to 5 ft. diam. can be driven up over the grizzly and out on the dump with fairly good pressure and a moderate head of water. Wings must be conducted at every move to draw and drive against, as shown in the illustration. These figures of actual operation of the machine at the Red Hill will give some idea of the capacity to be obtained. Depth of bank, about 20 to 25 ft.; average dump, 10 ft.; gravel, heavy, containing boulders up to five tons in weight; capacity when running, about 1200 cu. yd. per day; amount of water required, about 1200 inches in two No. 3 giants, operating under 450-ft. pressure. When water is light, by shifting from the field giant to the elevator giant at intervals, 600 in. will give a duty of nearly 1000 cubic yards.

The method of operation is as follows: The elevator drive giant is set fairly in front of the elevator, at a distance from the apron of from 80 to 100 ft. This remains fixed in its position throughout the run, and a shed may be built over

THE ELEVATOR AT WORK.

it to protect the elevator 'piper' from chance flying gravel from the field giant. The latter giant is used to cut down and drive up the gravel from behind and to one side of the elevator giant, and will easily keep the elevator giant busy. The operation of the elevator giant is the most important part of the whole thing, and requires a skilled piper, who by careless work can lose several times his wages in a very little while. As the mixed gravel is driven up to him by the field giant and stacked in front of the elevator, he drives it up on the apron and the solid portion of the elevator below the grizzly. Here the fine and the gold must be 'boiled out' upon the grizzly, and the utmost care must be taken not to throw the gold clear through upon the dump. Carelessness in this respect caused, in one case of which I know, the condemnation of this elevator and the installation of a hydraulic system which will give nowhere near so great capacity. After the fine has all been boiled out into the boxes (an operation which does not require a great deal of time), the dry boulders are then driven out over the grizzly upon the dump. As the width of the machine is about 8 ft., its capacity exceeds that of a 3-ft. sluice-box on an 8-in. grade with the same water and the same type of gravel, necessitating throwing out the water and wasting time with a derrick. In fact, it so far exceeds the capacity of the latter that I have seen 10,000 cu. yd. of gravel, averaging about 5c. per yard,

put through the machine with 600 in. of water, the dump piped out of the way by moving the elevator giant forward for that purpose and then resetting, and everything in shape for another run in the same position within twenty days. This includes cutting down and all the innumerable details of handling which necessitate dead work. At any rate, gravel worth 5c. paid all expenses during the time of handling, under conditions which by any other process I know would have been absolutely assured of a dead loss.

After the dump is filled up to the top of the grizzly, extensions can be built out upon it by laying stringers, or sills, and covering with ordinary 1-in. boards in two thicknesses. This extending process may be repeated several times before it becomes necessary to pipe the dump. A giant run specially for the purpose of piping the dump would, of course, save a good deal of time. By this means an acre per month, 20 ft. deep, could readily be put through without moving. Another good feature, if the water were available, would be to have a ditch along the side of the bar, parallel with the direction of working, which would supply about two hundred inches as a constant feed for the sluice-box. As in all gravel mining, care must, of course, be taken that the box does not clog up with sand and run over. About 50 or 60 ft. of riffles of the type described is amply sufficient for any sluice-box. The grade of the box should be steep.

The length of run that can be made with the elevator in one position depends, of course, on local conditions, and the length of drive available with the pressure and water. Good pressure is highly desirable with this type of machine. Care must be taken in each move to see that there is plenty of dump room. The fine dump, of course, piles up in front of the sluice-box and must be piped back every hour or so. This occupies more space than the coarse boulder dump at the back of the elevator, and it is advantageous to run it off into the river if possible. But by piping it back with a dump giant, where the water is available, after the first run has been made, the machine clears its own room so fast that with the slightest impounding space to start with, the entire detritus can be stacked back on the ground as neatly as any dredge in existence could do it.

After a run has been made, comes the chief loss in dead work; that of moving the elevator. The wings must be torn down, to be rebuilt when the elevator is again in place. Skids are then prepared, made of peeled poles blocked up level at intervals of about 8 ft. apart along the line of motion. Care must be taken to have the blocking firm and the skids braced. The apron is removed from the front end, and is handled separately. The elevator itself rests on long stringers running its full length, made of about 12 by 12-in. timber. These stringers slide over greased skids. Four men, together with a mule and a capstan for motive power, with $\frac{3}{4}$ -in. cable and triple blocks, can move one of these machines and set up the wings ready for operation in eight or nine days, including moving the giants and pipelines.

This dead work necessitates loss of water season. This can readily be obviated by having two machines on different parts of the bar. In fact, if the property is large enough, four machines would just about occupy the entire time of a moving crew, and gravel could be kept moving continuously over three of them, thus bringing down overhead cost caused by capital invested in original water equipment. In even the most isolated mountain regions, where timber is available, a machine of the size indicated can be built at a cost not to exceed \$3500, which is, of course, very slight compared to the cost of the average water installation. Four machines, on a 20-ft. bank, even of the heaviest gravel, should have no difficulty in moving ten acres of ground in a five-month water season. The operating cost, exclusive of overhead expense, in a country such as that of the Salmon river, would be about \$15,000, or in the neighborhood of 5c. per cubic yard.

These figures are based on actual operating experience in the Salmon river country, where the gravel is usually low grade and variable. With one machine in operation,

100,000 yd. is handled annually at the Red Hill, at an actual cost of about \$6000, or 6c. per cubic yard. Overhead cost, including amortization of capital, of course, brings this up. In short, the advantages of the system are these. Ground which would ordinarily require a derrick and a good dump can be worked to advantage, and ample room be found for the disposal of tailing, thus ensuring capacity, essential in working low-grade bars. Such ground, if worked by hydraulic elevator, would require constant clearing of pits, a great head of water (the average amount of solid matter handled being only 4% by weight compared to the weight of water necessary) and much more time lost in moving, as well as giving much less duty to the miner's inch. By using a large number of machines, and thus conserving the water season and cutting down overhead yardage cost, gravel of the type described can be handled at a total cost of between 6 and 7c. per yard, and gravel of the dredging type at a much lower figure.

Now for the second point. The use of machines of this type need not be confined to the Klamath and its tributaries, in this state. Locked in the gravels of the Sierras and of the northern tributaries of the Sacramento is a tremendous wealth, unavailable by reason of the nature of the ground for the dredge, and barred by the *débris* law from recovery by ordinary hydraulic processes without the use of costly impounding dams. Attempts have been made to handle some of this by hydraulic elevators, but they have failed for various reasons. As stated before, the hydraulic elevator in any given time moves but four parts in one hundred of solid matter. The remaining 96% consisting of water used in the operation of the elevator and in driving the material to it, represents a tremendous waste of power which should be used in tearing down and driving material. This excess water, further, is bound to carry a large proportion of the *débris* down to the rivers, and bring the operator at once into conflict with the law. On the other hand, a box elevator of the type described uses much less water, requires a much smaller drain, and deposits the tailing in piles similar to a dredge, so that by the use of a dump giant, the entire *débris*, with the exception of a small amount of silt, can be kept on the bar. In view of the enormous wealth which is at present tied up in these bars, cannot some ground be found, under these circumstances upon which the mining interests of the Sierras and the agricultural interests of the Sacramento valley can unite on a common footing? I can see no reason why they should not.

Of course, there are many improvements which will probably suggest themselves to the practical operator; improvements in rigidity and lightness of construction, tending to facilitate moving, as well as improvements which tend to eliminate the personal equation brought in by careless piping, and prevent loss of fine gold, jamming with boulders and similar evils; also to conserve all the water for the boxes. The machine as it stands, however, certainly deserves more general use than it has as yet received, and will be a means of solving the problems of many hydraulic operators confronted with a lot of poor-dump, low-grade gravel, as well as being of great assistance under more favorable conditions.

PETROLEUM IN ARGENTINA.—According to the report of the British Consul at Buenos Ayres, the discovery of petroleum in the north of Argentina has been confirmed by the result of a Government survey, and the Department of Mines has satisfied itself that the petroleum field is an extensive one, that the oil is of good quality, and that it lies near the surface. The entire district is being reserved for Government exploitation.

The Union of South Africa exported, during 1911, gold to the value of \$170,000,000, diamonds worth \$40,000,000, coal to the value of \$5,250,000, and copper in ore and matte worth \$3,000,000. The value of the tin exported was \$1,190,000, while it is interesting that ostrich feathers worth \$11,000,000 were exported during the year.

The Economics of Tube-Milling

By S. J. TRUSCOTT

*Referring to the original paper on this topic by S. H. Ball, the table (see below) registers the feed tests, among which Mr. Ball points to A as indicating the most efficient feed. The figures given under A, however, are not the actual figures of the test, but those after correction from the application of the moisture curve, whereby Mr. Ball would bring them from a condition of 33% moisture to one of 38%, at which the other tests were made. As I have pointed out, in making the correction for power

the number of tons crushed through 120-mesh per 24 hr., and it will be seen that for the experiment A Mr. Ball gives the highest figure of 3.96 tons. But this is a figure which can be shown to be entirely wrong. All the other results in that column were obtained directly from the actual figures of the different tests. With that for A, however, this was not the case. This was obtained by measurement from the curve where, between the points O and R, Mr. Ball has not ventured to put in the actual results for A, but has drawn a freehand curve which places A as high as he thought from his efficiency curve it ought to be.
Using the figures given by Mr. Ball, it can be directly calculated that the amount of material which would be

* Most efficient test of series.

Mr. Ball has made a serious mistake. The actual power consumed at 33% moisture is given as 5.3 hp. At 38% moisture, from the moisture power curve, it should certainly be less. However, Mr. Ball has increased it from 5.3 to 5.8 instead of decreasing it, noting with satisfaction that this figure conforms so well to the power-curve which he drew without its help. It will be seen that if this power had been logically corrected it would, on the contrary, have destroyed that curve.
It may be argued that in any case the results of test A, as they actually stand and without the advantage of the correction for moisture, still indicate the most efficient feed, the relative mechanical efficiency of that test being 7.76. By reference, however, to the table of crushing efficiency given in the original paper, it can be shown that that statement is open to very great doubt. In that table, which is derived from the feed tests, there is a column giving

crushed through 120-mesh, in that experiment, in 24 hr., is 2.79 tons, or, if it be increased to the greater efficiency of 38% moisture, 2.97 tons. With these figures—and they are the only ones which can be justified from the data given—the crushing efficiency of experiment A is far from being the best of the lot. It may be argued that crushing efficiency is not a measure of mechanical efficiency, since it does not take the power into account, but it is in any case an effective measure of the work done, and Mr. Ball in more places than one has not failed to recognize the correctness of the indication it affords as to efficiency. The relatively low crushing efficiency of this test A, therefore, subjects to considerable doubt Mr. Ball's conclusion that his results show a critical feed in the experiment A. In this connection I take the word "critical" to mean a position from which a small departure will cause a serious change of efficiency. To show the difficulty, however, of checking Mr. Ball's figures here and elsewhere throughout the paper, I would refer to the number of tons for the experiment C in this table of crushing

*From the *Bulletin* of the Institution of Mining and Metallurgy. A discussion of the article by H. Standish Ball, *Mining and Scientific Press*, September 23, 1911.

efficiency. This is given as 2.54, whereas in the general summary of tests near the end of the paper it appears as 2.34, and if it be worked out from the data on page 22 the figure 2.68 is obtained.

After the tests on feed come those for moisture. As Mr. Ball remarks, the outstanding feature of these tests is the great efficiency of a moisture of 37.7% above all others, this being the percentage of moisture in test B. It is seen, however, that this efficiency is due entirely to the lower power recorded. Further inspection shows this low power to be so singular as to require confirmation. This view is strengthened by reference to the moisture diagram. The black dots with circles around them in that diagram represent the power readings, and it is seen how entirely unsupported the position of B is, and how entirely isolated. So much is this the case, that there are, I think, few who would be bold enough to include it in drawing any power-curve. Mr. Ball appears to take comfort and confirmation from the fact, which he considers notable, that the power curve is practically the efficiency curve inverted. But the fact that when the power is given low the efficiency appears high, is a natural and not a notable fact. He would again fill the gaps in his own experiments by bringing other authorities to his help.

Walter Neal, who from his experiments concluded that there was a definite critical point in the percentage of moisture, is the first one named. It was he, indeed, who first used the expression "critical" in this connection; but, if his results be carefully examined, it will be found that out of his eight experiments the one made in the neighborhood of 39% moisture had the advantage of the others in the largest and coarsest feed, two conditions which might well of themselves account for the greater efficiency at that moisture. I do not, however, wish it to be thought that I consider that Neal's experiments are thereby completely vitiated. I believe that they point to a greater efficiency in the neighborhood of 39%, but I do not think that they indicate any critical position. Sherrod is quoted as considering 40 to 45% moisture as the best under the circumstances of his equipment, thereby indicating that in his opinion a range of good efficiency existed.

Of Smart, it is stated that in the tests carried out upon the Rand he found 38.5% as the most efficient, but on examining the reference to this authority, it is seen that when speaking of the introduction of Caldecott cones at a plant in Mexico, he said: "As under the conditions of this plant 38% moisture gives a considerably higher tube-mill efficiency than higher or lower dilutions, a satisfactory tube-mill product was in this way secured." He was not speaking of any particular moisture tests made, certainly not of any made upon the Rand.

Lastly, there are the experiments of Fox, of whom Mr. Ball says that he "discovered that, taking the power consumed in conjunction with the fine grinding, the most efficient moisture would be 39.6." On examining the reference to that authority, it is seen that Fox says: "Comparing Fig. 3 and 4, it would seem that after the percentage of solution in the pulp has reached about 35%, both the fine grinding and the power consumption stay reasonably uniform," a statement which shows that he was quite unaware that his experiments had indicated a critical moisture, at 39.6. These two figures are those given in Fig. 10 on page 46 of Mr. Ball's paper, but in transcribing the curve marked 'moisture efficiency,' a serious alteration in its properties has crept in, which places the highest efficiency at the moisture of 39.6, whereas the real curve shows that an equally high efficiency was obtained at about 35% moisture, this being the percentage which Fox himself selects for comment. It is further to be noted that if the power be taken into account, the highest mechanical efficiency in these experiments by Fox occurs with a moisture of 28.57 per cent.

Concerning the pebble load, three tests were made which appear to indicate that a light load is mechanically more efficient, though a heavier load crushes more, these results agreeing with those made by Fox.

Concerning the speed, four tests were made, from which it would appear that Mr. Ball's tests confirm general experience. A remarkable and somewhat doubtful result is that which shows that it might take considerably more power to drive a charged mill at a certain lower speed than a higher one, Mr. Ball's experiments having shown this to have been the case as between 33 and 37 revolutions per minute. It is true that toward the end of the paper Mr. Ball gives results which would indicate a lubricating effect of the feed. Such internal lubrication of the feed can be conceived, but speed as a factor of lubrication is decidedly more difficult to grasp, and until further confirmation of such a property of speed is available, it would appear more easy to conceive that the power readings may have been wrong, a possibility mentioned by Mr. James. There is, in fact, some reason to doubt the power readings throughout. In addition to the considerations just given, I have already mentioned the singularly low and doubtful power in the case of experiment B of the moisture tests. It is further pertinent to remark that the power consumed in the condition of 'running light' throughout the experiments varies also very considerably. It is stated that the "motor was first run light for a few minutes to enable the power consumed by the shafting, belting, etc., to be ascertained." Seeing that this is a carefully specified duty, it is pertinent to ask whence come, then, the variations from 2733 watts to 8640 watts in the power consumed for this purpose.

Finally, Mr. Ball desires to test his work by first calculating what the efficiency under certain set conditions would be, and then running an actual test under those conditions. He wishes to know what the efficiency would be at 7.2 tons feed, 35% moisture, pebble load of half volume, that is, 1200 lb., and 37 r.p.m. By calculation he finds this efficiency to be 4.27. He then runs an experiment, designated U, to test this result, and an efficiency of 4.32 is obtained. These figures agree well, but unfortunately the test U was carried out at 41 r.p.m. If it be argued that in stating the problem the figure of 37 was by mistake given in the place of 41, and that this was obvious from Mr. Ball's calculation on page 50, that explanation may be accepted. But in such a case the problem represents, with only one variable, the conditions under which the test P was run, this variable being moisture, and the efficiency given to that test in the statement on page 13 has only to be corrected for moisture. This correction should therefore be carried out on exactly the same lines as the correction for the experiment A previously considered, the two positions being as follows:

Experiment A.		Experiment P.	
Actual conditions.		Actual conditions.	
Feed	18.6 tons	Feed	7.2 tons
Moisture	33%	Moisture	38%
Pebble load.....	1200 lb.	Pebble load.....	1200 lb.
Rev. per min....	41	Rev. per min....	41
Efficiency	7.76	Efficiency	4.45
Required the efficiency at 38% moisture.		Required the efficiency at 35% moisture.	

It will be seen, however, when comparing the calculations, that the two were not conducted upon the same lines. In both cases reference was first made to the moisture curve, and a difference between the two moisture efficiencies was obtained. On page 14 of his paper this difference was treated proportionally to figures of tonnage, whereas on page 50 it was treated proportionally to figures of efficiency. One method or the other must therefore be wrong.

In conclusion, Mr. Ball made an experiment under conditions all four of which represented, according to him, critical conditions, and he obtained a result which, he says, surpassed expectations. It would have been thought that if Mr. Ball had had a clear conception of the problem in hand he would have essayed to calculate the possible result, and that he has not attempted to do so weakens the force of his arguments considerably; there is little doubt also that had he done so his calculated result would

have been very much higher than actually obtained. This final test gave an efficiency of 8.82, a figure the significance of which can be readily challenged. On page 54 the figures of the actual test are given, from which it can be calculated that the crushing efficiency developed under those four critical conditions was at the rate of 2.97 tons per 24 hr. Comparing this efficiency with those given on page 14, it is seen that, neglecting that of A, which is incorrect, it is surpassed by two others, namely, O and R. If, therefore, any gain of relative mechanical efficiency has resulted, it has been brought about at the expense of a loss in crushing efficiency. There is another side from which this result of 8.82 may legitimately be challenged. On page 4 Mr. Ball states the general experience, in saying that "high efficiency could be obtained only by feeding a sand containing a minimum of slime." Reference to the gradings of the sand fed in these experiments will show that, whereas the sand of this last experiment contained only 12% of material passing 120 mesh, the average amount in the case of the others was 18.8%, and there was not one which came nearer than 16.5%. In other words, the material fed in the case of the last experiment was appreciably coarser than in all others, and the result of 8.28 was obtained, therefore, under exceptionally favorable circumstances outside of the four conditions of the test.

Nigerian Tinfields

By A. M. CHAMBERLIN

The Nigerian tinfields, which for the past three years have been attracting the attention of the English tin interests, are in northern Nigeria with Naraguta (Lat. 10°N., Long. 9°E.) as a centre, and covering a territory approximately 140 miles in diameter. They are reached by steamer from Liverpool to Forcados at the mouth of the Niger river. Thence by river steamer 450 miles up the Niger to Baro. Thence 225 miles up the Baro-Kano railroad to Riga Chikun. Thence by road 140 miles to Naraguta. Transport over this road is by carriers, and requires eight days. To avoid this delay a branch railroad is being built from Zaria, about 50 miles up the railroad from Riga Chikun, to Naraguta, which is expected to be completed this spring. Even with this road, the freight charges to England amount to upward of \$120 per ton.

The attention of Europeans was first called to these deposits by natives bringing metallic tin to the trading posts of the Niger Co., Ltd., on the river. Investigation by H. W. Laws, the agent of the Niger Co., Ltd., showed that the natives were operating a primitive sort of smelter at Liruei, to which ore was brought from over a considerable territory. He located on, and began developing, what has since become the Naraguta mine, which has been shipping ore regularly for the past six years.

All the tin won so far has come from alluvial deposits bordering the streams and ranging in depth up to twenty feet, and most of it has been won by calabashing, though ground-sluicing is being introduced to some extent. The tin occurs as black cassiterite, generally associated with topaz, ilmenite, and magnetite. It has been found in place of granite in several places, but so far as developed (August 1911) has been of very low grade, not over 8 per cent.

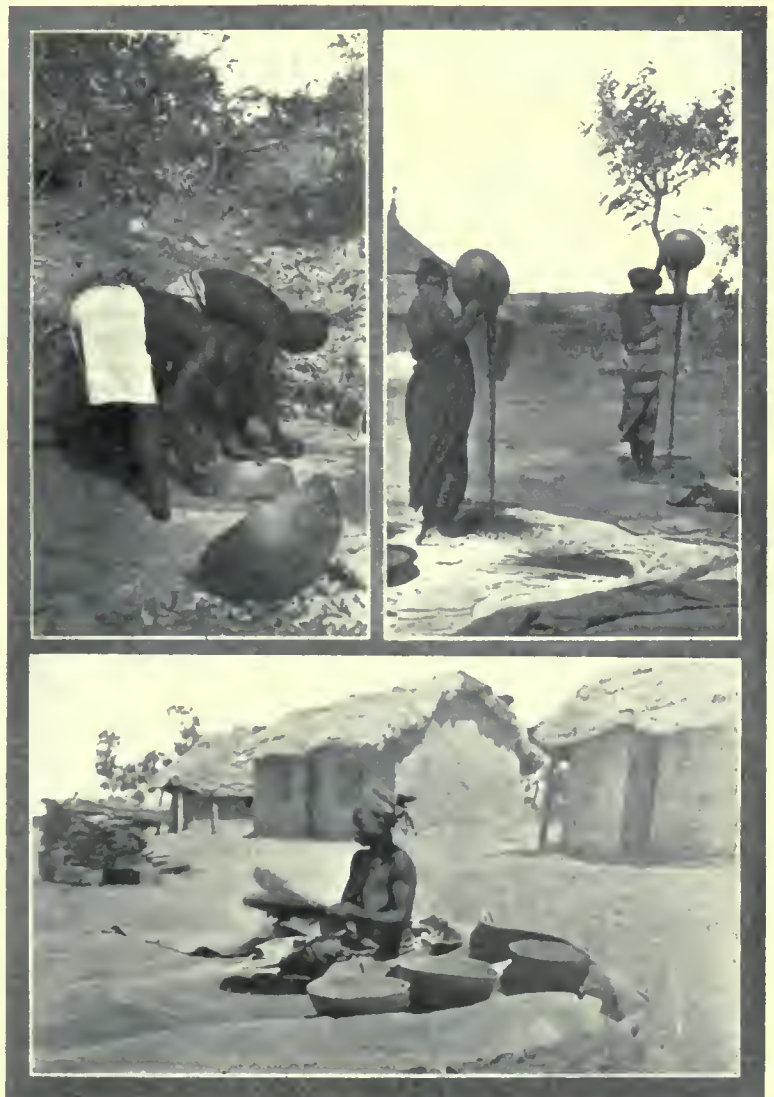

The country is fairly well settled with three types of natives: (1) The pagans, who are the tillers of the soil and supply most of the native food. They make good workers when they can be obtained, but cannot be counted

on for any length of time, as they consider their crops of first importance. (2) The Fulani, a much lighter-colored race than the others, are the herders of the country, keeping cattle, sheep, and goats, as well as doing some trading. (3) The Hansa, the rulers of the country prior to the English occupancy, are principally traders. They, with the Fulani, furnish the bulk of the laborers, but as they have not yet learned the value of money it is difficult to get any hold over them, and the labor is expensive even at the prevailing price of 18c. per day.

Mines and Minerals of Macedonia

By JOHN L. BINDA

*Since remote times the soil of Macedonia has had the

NATIVE METHODS OF TIN RECOVERY, NIGERIA.

reputation of containing many precious minerals. Not only was this stated by historians, but it is evident by the remains of great works undertaken by the ancients in the mining centres and especially on the peninsula of Chalcidice. These works reached the highest point of development under Philip of Macedon and Alexander the Great. These mines were worked for gold and silver, which were found in great quantities. During the medieval period and for a time under the rule of the Turks, mining was practically abandoned, except a little on the peninsula of Chalcidice at the beginning of the nineteenth century.

Forty years ago there was a revival of the mining industry of Macedonia, and many mines were opened by

*Abstract from *Daily Consular and Trade Reports*.

foreigners and natives. Attention was first paid only to the deposits of chromite, but later important discoveries of manganese, antimony, and arsenic were made. Of still greater importance was the discovery of deposits of pyrite and magnesite. The work undertaken for mining lignite and argentiferous galena was not successful. Since 1907 there has been a halt in the mining operations of Macedonia, caused by the discovery of great deposits in New Caledonia and in South Africa. Strong competition sprang up between these two countries, and in a short time the price of chromite dropped from \$25 to \$12.50 per ton c.i.f. On account of transportation difficulties, bad roads, and distance from the sea, the mines of Macedonia could not compete with these prices and were all forced to close down. The only company now working on a large scale is the Société des Mines de Cassandra, whose production of magnesite for the next eight years has been sold to German companies. The following is a descriptive list of the principal mines of Macedonia, most of which are not being worked on account of the low prices for the ore and high cost of production:

MINES OF CASSANDRA

In the northeast of the peninsula of Chalcidice, near the shores of Straton, are the mines of the Société Ottomane des Mines de Cassandra, formed in 1892 with \$675,500 paid-up capital. The concession includes the regions of Isvoro, Mahala, Horuda, Lipsada, and Varvara, districts in which minerals are abundant and which were worked in ancient times by Greeks. The principal mineral now being extracted is pyrite, of which large masses, estimated at about 3,000,000 tons, are available. About 1500 men, mostly Greeks, are now employed. The pyrite, which contains from 47 to 50% sulphur, is exported to Germany, Italy, and France, where it is used in the manufacture of acid. This company exports 130,000 to 150,000 tons per year, which is transported by the automatic Decauville railroad. As the pyrite must be delivered in powder form, the company has a modern plant for washing and treating the ore. An electric plant for the mine is being installed. At first the company gave its entire attention to the mining of manganese, but lately it turned its attention also to the iron pyrite and other minerals.

CHROMITE MINES

The *Ostrovitza mine* is 25 miles from the station of Ferisovik, the latter being 185 miles from Saloniki. Its ore is of a good quality, averaging 48 to 52%. This mine was worked from 1903 to 1907, during which time 9000 tons of chromite was extracted. Work has been suspended on account of low prices. The mineral was transported to the railroad on horseback and by small wagons. The cost of ore per ton f.o.b. Saloniki was \$12.94, divided as follows: extraction, \$1.32; transportation, from mines to Ferisovik, \$5.06, from Ferisovik to Saloniki, \$2.68; paid to holder of ancient concession, \$1.20; customs duty and Government revenue, \$1.93; charges for loading aboard steamer, 75 cents.

The *Roshdan mine* is in the Caza of Tikfesh, about 30 miles from Krivolak station, which is 90 miles by rail from Saloniki. The ore is excellent, containing from 50 to 54% chromite. During 1903 to 1906, while this mine was worked, about 5000 tons of ore was produced. All transportation to train was on backs of animals. The cost per ton f.o.b. Saloniki was \$12.64, divided as follows: extraction, \$1.54; transportation, from mine to Krivolak, \$4.84, from Krivolak to Saloniki, \$2; aboard ship, 75c.; customs duty and Government revenue, \$1.93; paid to previous owners, \$1.58.

The *Radousha mine*, in Vilayet of Kossovo, is 16 miles from Uskub, which is 152 miles from Saloniki. The quantity of ore in sight is very large and the quality is excellent, the assay showing 49 to 51% chromite. This mine has been very irregularly worked during the past 15 years on account of underground streams, which necessitated the installation of steam pumps. The ore is transported from the mine to Uskub by wagons. The cost of ore per ton

f.o.b. Saloniki is \$10.43, divided thus: extraction, \$2.86; transportation, from mine to Uskub, \$1.85, from Uskub to Saloniki, \$2.25; on board ship at Saloniki, 75c.; paid to holders of ancient concession, 88c.; customs duty and Government revenue, \$1.84.

The *Allshar mine*, in the Caza of Tikfesh, is 30 miles from Krivolak. Not much work has been done, but enough to show sufficient ore to warrant its further development and of a quality ranging from 50 to 52% chromite. During 1906 over 300 tons of ore was extracted. Its cost per ton f.o.b. Saloniki totals \$11.07.

The *Loyan mine*, in Caza of Comanovo, is 5 miles from Tabanoftehe station, which is 130 miles from Saloniki. On account of the large quantity of ore extracted, this mine is now of little importance, although engineers state that deeper diggings may show the continuation of old veins or bring new ones to light. From 1890 to 1896 this mine produced about 17,000 tons of ore. Cost of ore per ton f.o.b. Saloniki is \$8.27.

The *Sfiltshe mine*, in Caza of Cosina, is 37 miles from Caraferia, which is 42 miles by rail from Saloniki. Three veins of good ore are visible, but in their present state they do not show evidence of great importance. There is, however, a vein of low-grade chrome ore, averaging about 45%, which is of value. About 2000 tons of ore has already been extracted. The ore is transported from the mines to Caraferia on horseback, the cost per ton f.o.b. Saloniki being \$12.05, divided as follows: extraction, \$2.20; transportation, from mine to Caraferia, \$6.16, from Caraferia to Saloniki, \$1.10, on board boat, 75c.; customs duty and Government charges, \$1.84.

The *Varissa mine*, near the Sfiltshe. The workings to the present have shown good enough results. The ore can be delivered f.o.b. Saloniki for \$11.18.

The *Goranza mine*, in Caza of Uskub, is about 12 miles from Eleshan station, which is 167 miles from Saloniki. The ore costs \$9.37 f.o.b. Saloniki.

The *Tourhanli mine* is near the thermal baths of Sedes, about 10 miles from Saloniki. A vein of sufficient importance has recently been brought to light. The ore averages about 48%, and it is brought to Saloniki in wagons. The cost per ton f.o.b. Saloniki is \$5.72, divided thus: extraction, \$1.76; transportation, from mine to Saloniki, \$1.54, on board, 66c.; customs duty and Government revenue, \$1.76.

The *Ghiuredjik mine* (manganese and argentiferous galena), is situated in the Boz-Dag between Drama and Zirnovo. Two deposits have been found, a pocket of manganic oxide and a vein containing lead, antimony, copper, and iron. About 800 tons of manganese has been extracted by surface mining, and signs show that there are other deposits which could be reached by sinking. The Radibosh mine, containing a large amount of manganese, is in the immediate vicinity of the Ghiuredjik mine. The mines of Yanievo and Novo Bordo are in the Vilayet of Kossovo, Caza of Ghilan. They contain important veins of argentiferous galena.

COAL mined at Cambria, Wyoming, is interesting because it is claimed to be gold bearing. Some of the coal has contained as much as \$2 per ton in gold and was sold for only \$1.50 per ton. When coke made at Cambria was selling for \$3.50 per ton, samples were taken from 31 cars during a period of three weeks and assayed. The samples showed an average of \$2.46 per ton in gold and 28c. in silver. The explanation offered for the presence of gold in this coal is that the sands which submerged the old peat bog and now form the roof of the coal bed were derived in part from gold-bearing alluvium. While the sand was being deposited the gold worked down into the underlying bog and is now found in the coal. This is described in Bulletin 499, U. S. Geological Survey, 'Coal Near the Black Hills, Wyoming-South Dakota,' by R. W. Stone. Besides a description of the coalfield and coal-mining operations at Cambria, which is 7 miles north of Newcastle, Wyoming, the report contains a description of all known coal exposures around the Black Hills.

The Mascot Orebodies

By F. L. SIZER

*The following is the result of a preliminary examination of the property of the Mascot Copper Co. Because of the great extent of the holdings, I have considered only what I deem to be the most important features of the mine, both surface and underground, and it is not possible with so short a study of the conditions to present a full report. I am quite ready, however, to express my conception of the main points which need to be discussed, and here the salient features are briefly discussed.

Equipment.—The equipment is quite sufficient for the property in the development stage, and will not need to be materially increased until the company is prepared to make a regular daily output. The power-plant is specially well designed and situated, so as to command the mine requirements, and can be expanded by the addition of other units. The houses and boarding facilities, for men and officials, are comfortable and sanitary, well operated, and carefully supervised. The camp is clean and well supplied with good water and bodily comforts for the men, thus insuring the best class of employees.

Surface Conditions.—There are many large outcrops of mineral-bearing veins upon the surface of the claims owned by the Mascot Copper Co., and the size, extent, and mineral content of these outcrops are so favorable as to compel an opinion which is optimistic, while yet being conservative, as to the probable existence of large orebodies in depth. The appearance of copper sulphide ore, at and near the surface, is a most significant promise of persistence of the ore in depth, and the fact that profitable bodies of chalcopyrite have already been cut in the Consolidated adit-level, at a depth of 500 ft. below the surface, would seem to answer the query which has been in the minds of some people as to the kind of ore which will be found in underground development. In other words, the surface conditions are such as to influence one familiar with copper mines in saying that all indications point plainly to the existence of large commercial bodies of copper ore, carrying gold and silver, throughout a great extent laterally, as well as in depth, within the limits of the territory owned by the Mascot Copper Co. The management has wisely provided against any possible mining litigation by acquiring all surrounding and outlying claims that by any possibility affect apex rights, and are patenting the claims as rapidly as the necessary work upon them is completed.

Underground Development.—Although a large amount of driving and cross-cutting has been done, much remains to be accomplished before I can say that ore is 'blocked out' in the mine ready for extraction, and, as you well know, the labor of developing a copper mine is enormous and the time required to do it is long.

Smelter Returns.—The grade of the ore has been positively determined by several carload shipments, returns on which have been shown to me and the places from which the ore was taken designated by E. A. Ely, the superintendent, and I have confirmed these results, on different classes of ore, by my own sampling. The sulphides will, of course, prove to be the permanent orebodies of the mine, and must be critically examined and records kept of all grades of ore found, in any of the workings, wherever it occurs; not ignoring the low-grade ore, which may in time prove to be of sufficient quantity and importance to be treated by concentration, aside from those bodies which are known to be smelting ore.

Supervision.—The work of opening the mines has been intelligently planned and judiciously executed, and I wish to congratulate you upon the evident ability and devotion to the company's interest, evidenced by your consulting engineer, Captain Tibby, and E. A. Ely, the superintendent.

Recommendations.—Were I to undertake to advise you at

*From a report made to the management of the Mascot Copper Company.

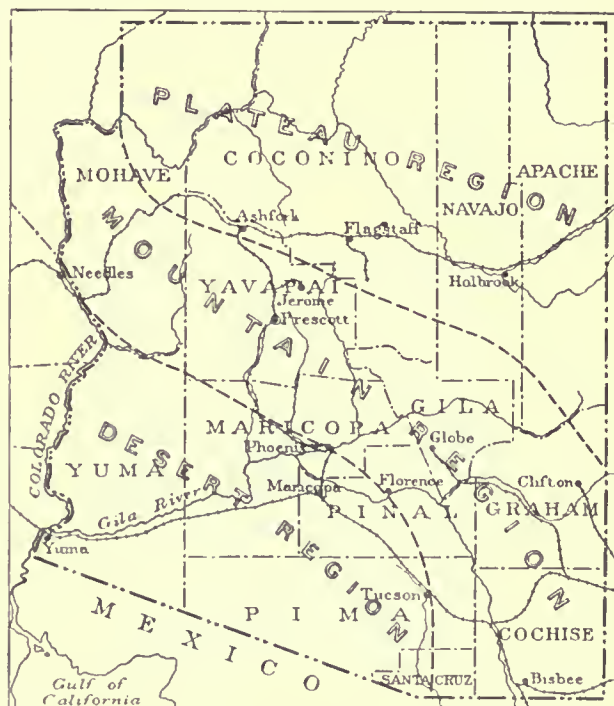

this time on the whole field which necessarily must come under my observation later, you would rightly be suspicious of my judgment, but there are some points clearly in mind which are, in my opinion, of permanent importance, and my recommendations are therefore as follows:

(a) Trace and develop, by means of the raise now extended 60 ft. above the Consolidated adit-level and the winze 200 ft. deep below it, the orebody which, to date, has yielded the highest-grade sulphide ore and has promised most favorably as to size and grade of copper contents.

(b) Undercut and develop the known orebody in the 100-ft. level of the Oregon shaft by a new level driven from this shaft at a depth of 220 ft. from the surface, and later by work over the collar of the winze, where some short cross-cuts have already been driven.

(c) Ascertain full length of ore-shoot and total vein width at several points in the black oxide vein, above and below the No. 1 adit-level and trace a connection between this and other surface workings.

(d) Rush the diamond-drill work as rapidly as possible

MAP OF ARIZONA. THE MASCOT MINE IS AT DOS CABEZOS IN COCHISE COUNTY.

without interfering with other expenditures for development and determine the position, width, and value of ore-shoots in the copper vein at a depth of 900 ft. in No. 1 adit, and later such other diamond-drilling as may be consistent with the ideas gained in the near future, by studying all the workings accessible from the Consolidated adit.

Conclusion.—If it were merely a matter of expressing an opinion as to the value of one metalliferous vein, I might say to you, in language more definite, my estimate of the property, but having to deal with so large a territory, showing as it does outcroppings of so many large and generously mineralized veins, situated so advantageously for cheap development, I can say with emphasis that in my opinion the continuation of the present policy of development will result in opening a large and profitable copper mine, which has now the ear-marks of one of the best of its class.

ORE RESERVES of the East Rand Proprietary Mines on January 1, 1912, are given as 6,716,600 tons of 6.9-dwt. ore of stoping width, and 11,150,400 tons of 2.6-dwt. ore; a total of 17,867,000 tons averaging 4.3 pennyweights.

THE Aandal copper mines, formerly worked by the Telemarken Copper & Smelting Co., have been taken over by the Bandak Elektrolytiske Kobberværk, which has a capital of 500,000 kroner.

The Boundary District in 1911

By WILLIAM FLEET ROBERTSON

*There was a comparatively large net decrease in the quantity of ore mined in the Boundary district—about 454,000 tons net, or 26.5% decrease. This was due mainly to the strike of the coal-mine employees in the Crows Nest district, which cut off the supply of coke for the Granby company's furnaces. The decreases were: Granby company's mines 469,000 tons, and Snowshoe 111,000 tons; the increases were: British Columbia Copper Co.'s mines 115,000 tons, and Hedley Gold Mining Co. 11,000 tons. The net decreases in metals recovered were, approximately: gold, 24,000 oz.; silver, 147,000 oz.; and copper, 6,592,000 lb. Against the large decrease in the production of the Granby company, and the much smaller one of the Snowshoe, must be placed the substantial advances of the British Columbia Copper Co. (including the New Dominion Copper Co., which it now controls) and the Hedley Gold Mining Co. There were fewer small mines shipping ore in 1911 than in 1910.

Granby Con. M. S. & P. Co.—This company shipped from its mines at Phoenix 605,880 tons of ore, as against 1,074,867 tons in 1910. There was also received at the company's smelter at Grand Forks more than 1200 tons of ore from other mines in British Columbia. Operations were resumed in December at the mines and smelting works after nearly six months inactivity. No great amount of development work was done during the year, yet it was kept ahead of ore extraction to the extent necessary for economical working of the mines. The chief exploration work was done with diamond-drills, which resulted in adding somewhat to the known reserves of ore. New ore was developed on the Victoria, Etna, Knob Hill, and Monarch claims, mainly on the upper levels, so that this ore can be extracted through existing main outlets from the mines. The general manager reported that during the fiscal year ended June 30, 1911, additional ore amounting to nearly 1,250,000 tons had been blocked out, while the quantity shipped in that period was 957,200 tons, so that the ore in sight had been increased by 291,000 tons, leaving 6,720,000 tons developed. The aggregate quantity of ore produced by and shipped from this company's mines at Phoenix during all years to the end of 1911 is approximately 7,250,000 tons. The ore continues to be about the average grade, though much lower in metal content than that mined ten years ago; however, it is now practicable to mine and smelt at a profit ore that would then have been thrown on the dump. The additions to plant and buildings in 1911 were chiefly those requisite to replace at the mouth of No. 3 adit those destroyed by fire in 1910. Construction materials used in several of the new buildings are fireproof brick, concrete, and iron.

At the Granby company's smelting works there was little new construction or additions to plant, other than a slag-disposal plant which was put in and was ready for operation by the end of September. The main features of this are: granulation of the slag by water; fluming of granulated slag to centrally situated storage-bins; dewatering of slag and carrying it on conveyor-belts up an incline to a maximum height of 100 ft. above the level of the present slag dump, and distributing it there. It is estimated that this change will provide dump room for from 6,000,000 to 10,000,000 tons of slag. It is noteworthy that in his report for the last fiscal year the general manager stated that "notwithstanding the lower tonnage shipped (950,563 tons as against 1,175,548 tons) and the disadvantages under which it was mined by starting and closing the operation of the mines at various periods, the cost of mining was only 1c. per ton greater than the year previous, while the cost of smelting was reduced 3c. per ton." The smelting costs were the lowest ever reached by this company, and are stated to compare favorably with any in the world. Late in the

year the settlers below the blast-furnaces were changed from water-jacketed to dry, with larger settlers, retaining the two-settler arrangement. Copper losses were low, less than 5 lb. total; an average slag of 45% silica was run. The mining and smelting costs of the large companies in the Boundary district are extremely creditable to the managements and render possible the treatment of such low-grade ores.

The Granby company's mining costs for crushed ore f.o.b. cars was 84c. per ton, and the smelting, from ore to pig copper, was less than \$1.29 per ton, on a quantity of 960,000 tons. Railway transportation is not included in this. The British Columbia Copper Co.'s costs, under somewhat differing conditions and on a smaller tonnage of 352,000 for fiscal year, were equally creditable, namely: mining, 90c. per ton f.o.b. cars; the smelting cost was \$1.40.

British Columbia Copper Co.—This company increased its production of ore by about 25%, thus making the output from its mines (including those of the New Dominion Copper Co., which it also operates) about 550,000 tons. More than half this ore came from the Mother Lode mine, and the greater part of the remainder from the Rawhide mine. The Wellington group and adjoining Athelstan in one part of the district, and the Emma in another, together shipped between 40,000 and 50,000 tons. The company also obtained about 15,000 tons from its mines in the state of Washington. The most important work done in the company's own mines in 1911 was in connection with the method of breaking down and extracting ore initiated at the Mother Lode mine the previous year by E. Hibbert, mine superintendent, and continued in 1911. This consisted of dividing the ore-body into a series of transverse stopes of a maximum width of 25 ft. and breaking the ore down in large quantities. An idea of the extent of these stopes may be obtained from the following brief particulars of one blast, in preparing for which 2433 holes, averaging 14 ft. each in depth, were drilled. The explosive charge consisted of 425 boxes of 40% dynamite (equals 10 $\frac{5}{8}$ tons), and 2525 electric detonators, low tension No. 7, were used. Connection was finally made to a 550-volt circuit. The result of this blast was to break down more than 100,000 tons of ore. Despite the high cost of Pennsylvania coke imported during the eight months that the Crows Nest coke was not obtainable, the company operated three blast-furnaces at its smelting works at Greenwood, except that in November the smallest one was cut out until Canadian coke should be again obtainable, the settlement of the strike having been then assured.

The British Columbia Copper Co. was active last year in its endeavors to secure more mines. The McKinley and Riverside groups, in Franklin camp, Grand Forks Division; the Voigt group near Princeton, Similkameen; and the L. H. group, in the neighborhood of Silverton, besides some claims near Greenwood in the vicinity of the Mother Lode mine, were bonded under option of purchase, should the results of development work warrant their acquirement. A group of 15 claims in Washington, a few miles from Grand Forks, was also bonded. In addition to this varied exploration work, diamond-drilling was done on the New Dominion Copper Co.'s Montezuma claim near Phoenix. The company's relations with the miners' and smeltermen's unions were harmonious throughout the year, consequently there were not any labor troubles to interrupt operations at the mines or smelter.

Consolidated M. & S. Co.—This company continued to work the Snowshoe mine under lease until April, and then closed it after having shipped in 1911 nearly 31,000 tons of ore, as compared with 142,600 in 1910. This alone will account for a decrease in production of copper of 1,800,000 lb. The Snowshoe lease has since been abandoned. Some 2200 tons of ore was shipped from the Phoenix Amalgamated, but at the then price of copper the grade of ore was too low for profitable working. Ore received at Trail from the company's No. 7 mine was 775 tons during the first quarter of the year; none was shipped afterward. Development work was continued until suspension for the winter. The ore-sorting plant was completed and ore-bins were erected at the lower end of the tramway.

*Abstract from a preliminary estimate by the Provincial Mineralogist.

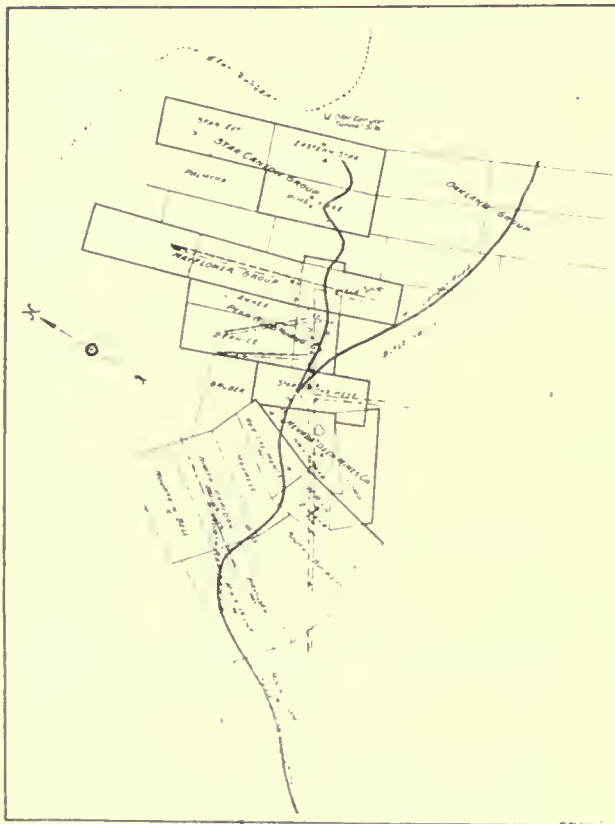

Como, Nevada

By H. C. CUTLER

Como is in the Palmyra mining district, in the Pine Nut range, some ten miles in a southerly direction from the old town of Dayton, the nearest railroad point. It was discovered in the early sixties and its first boom was contemporaneous with that of Virginia City. At one time the population was several thousand and the busy main street was lined with stores and saloons; even a brewery, to keep the inhabitants from getting thirsty, could be found. Some surface work was done on the large quartz outcroppings, and several shallow shafts sunk, but the greater attractions of Virginia City gradually drew the whole population away before the area was thoroughly prospected. After this, mining was carried on in a desultory manner, with some success in one or two properties, until 1910, when there was absolutely no activity whatever. Guffy

erty was sold to H. L. Taylor, of New York and Toronto, for a figure approximating \$75,000. The mine was then opened to the 300-ft. level by a shaft, but with no stoping below the 200-ft. Development work has shown that the old shoots are persistent, and has also disclosed new high-grade ore-shoots. At the present time the mine is opened by a double-compartment shaft 360 ft. deep, with levels at 115, 200, and 300 ft. Stoping is in progress above the 200-ft. level and the 300-ft. is being unwatered. The main power-line of the Truckee River General Electric Co. crosses the property, and all the equipment is electric. A 50-hp. electric hoist, an Aldrich electric sinking-pump, and the mill are run by electric motors. The old mill, consisting of one 3-stamp and one 5-stamp battery (750-lb. stamps), with plates and an outdoor cyanide tailing plant, is still used, although it is understood that the present owners will erect a complete up-to-date plant in the spring.

So far as I can learn, no complete geological survey of this district has ever been made, and no mention of it in any of the bulletins of the U. S. Geological Survey can be found. The principal properties lie in a basin at the head of the east branch of Eldorado canyon. This basin is surrounded on three sides by high ridges and peaks, the topography in some respects resembling that of Virginia City. There is considerable second-growth pine in the hills, and, unlike the desert country surrounding, water and verdure abound. The main mineralized zone, several hundred feet in width, strikes northeast. Cross-

COMO DISTRICT, LYON COUNTY, NEVADA.

& Galey, large Pennsylvania oil operators, after having spent nearly a quarter of a million in developing the Buckeye and North Rapidan properties to the point where they were ready to produce, got into financial difficulties in the East and went into the hands of a receiver. This resulted in the shut-down of the mines. The Como-Eureka, with a shaft down 300 ft., and a patched-up second-hand mill, produced over \$250,000 in bullion, and then for several causes succumbed. During this general discouragement the Holly-Logan mine, bonded for a large sum, was abandoned, and the mine and 10-stamp mill have been idle ever since. A number of other promising prospects have been held for years with a minimum amount of work.

It was supposedly a dead district, with a bad past and an unpromising future, when Edwin Baruch and C. O. Erixson took a bond and lease on the old Como-Eureka in November 1910. The property was then owned by a Mr. Rea of Dayton, Nevada, who still had faith in the district and had hung on for years. The lessees started cleaning up the old workings, and by spring had opened some shoots of high-grade ore as well as a large amount of milling ore. In September 1911 control of the prop-

HEAD-FRAME, PEER G. M. CO.

fissuring, as evidenced by north-and-south quartz dikes, is frequent. These quartz dikes are mineralized in several instances; in the North Rapidan and Ely properties, enough to make commercial ore.

The entire district is in the later eruptives, and the 'lode porphyry,' to use a Nevada term, is hornblende andesite, similar to that found in the hanging wall of the Comstock. Several later flows of andesite can be recognized in the higher portions of the range, and in many places these are capped by a still later flow of basalt. In the mineralized portion of the district, situated in the basin above mentioned, these later flows have been eroded, exposing the lode porphyry and the mineral-bearing veins. It has not as yet been determined whether the hornblende andesite is intrusive or a flow. The volcanic breccia, which is quite prominent in Gold canyon on the road from Dayton to Virginia City, shows again on the east side of the Pine Nut range below Como. It is believed that this range is contemporaneous with the Virginia range and the period of mineralization of both the same.

At Como the fissuring has been extensive, and at least two periods of ore deposition can be distinguished. The ore is similar to that generally found in the later eruptives, in that it is a silicified and replaced country rock. At and near the surface, gold is the chief valuable mineral. This is especially true of the main east-and-west veins. The silver minerals are more prominent in the north-and-south fissures, and the gold and silver are more nearly equal in the deeper ores. Some evidence of copper appears in spots

in the oxidized zone, but not enough to indicate a quantity sufficient to interfere with milling, even in depth. Plating and cyaniding now secure an extraction of over 90%, but it is quite probable that concentrating will have to be added to secure this percentage when the base ores are milled.

Having lain practically dormant for so many years, the district has now taken a new lease of life, considerable activity is being displayed, and, stimulated by the success of the Como-Eureka, which is now known as the Nevada Deep Mines Co., prospectors and mining men are investigating and in several instances developing some of the more promising prospects. The Star of the West claim, adjoining Nevada Deep Mines Co. on the northeast, is being developed, and high-grade ore showing considerable free gold is being taken out and sacked for shipment. Some of this ore assays as high as \$1500 per ton.

The Peer mining claim, directly northeast of and adjoining the Star of the West, together with two adjacent claims, has been incorporated as the Peer Gold Mining Co., and development work is in progress. The northeast mineralized zone traverses this property for its entire length, and ore assaying up to \$3000 per ton has been found on the surface. A 30-hp. electric hoist has been installed, a head-frame, blacksmith-shop, and all necessary buildings erected, and a crew of ten men is working steadily. The shaft, 4 by 7 ft. in the clear, is down about 40 ft. and will be sunk to the 200-ft. level, at which point the veins shown on the surface will be cross-cut and driven.

The Paramore, Ely, Oakland, and Logan properties are all promising prospects, showing some good ore in strong veins, and no doubt will be developed this coming summer. This is an interesting district from a mining standpoint, and, judging from the amount of gold at the surface, the finding of extensive ore-shoots should be comparatively easy for the modern prospector. Supplies and wages are reasonable, and, as the district is situated at an altitude of 6500 ft., the summers are cool and the winters not severe. The road to Dayton is excellent and automobiles can be driven directly into town. Its accessibility is a great feature, and all indications point to a considerable boom this summer.

Copper Producers' Association Report

The Copper Producers' Association April statement shows a decrease during the preceding month in accumulation in this country of 572,431 lb. The details are as follows:

	Pounds.	
Stock of marketable copper of all kinds on hand at all points in the United States March 1, 1912	62,939,988	
Production of marketable copper in the United States from all domestic and foreign sources during March	125,694,601	
Deliveries of marketable copper for consumption and export during March.....	67,847,466	
Stock of marketable copper of all kinds on hand and at all points in the United States April 1.	62,367,557	
The changes in surplus since April 1, 1911, have been as follows, in pounds.		
	Increase.	Decrease.
April 1911	3,547,974
May	440,024
June	8,561,768
July	19,695,306
August	4,297,357
September	7,453,355
October	5,897,214
November	23,212,454
December	22,330,493
January, 1912	22,173,252
February	3,301,944
March	572,431

RECEIPTS of the United States Government from the sale of mineral lands in the Western states during the past

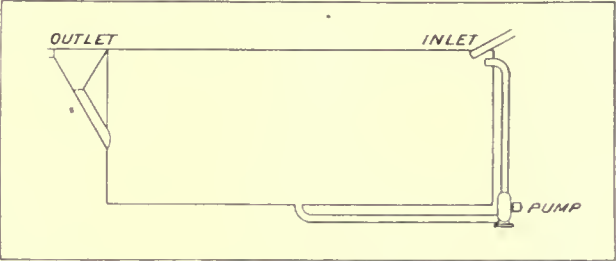

ten years, according to the *Bulletin* of the American Mining Congress, have been as shown in the accompanying table.

Coal Lands, Separate.	Mineral Lands, Separate.	Coal and Mineral Lands, Aggregate.
\$ 200,116.35	\$ 162,516.50	\$ 362,632.85
171,641.81	291,081.39	462,723.20
486,176.54	303,907.02	790,083.56
385,276.97	300,391.68	685,668.65
269,458.55	282,518.25	551,976.80
523,905.72	275,983.55	799,889.27
288,092.82	282,322.94	570,415.76
599,920.44	287,022.25	886,942.69
471,088.08	321,413.58	792,501.66
618,828.04	271,557.87	890,385.91
\$4,014,505.32	\$2,778,715.03	\$6,793,220.35

During these ten years the entire fund arising from the sale of public lands has amounted to \$65,357,107, which has been devoted to the upbuilding of agricultural interests in the public-land states. During this time the mining industry in these states has fallen far behind agriculture in progressive development.

Agitating and Circulating Solutions

Continuous agitation of solutions at the same time that a continuous flow through the system is maintained, can be easily effected by means of the arrangement sketched below. This plan was designed by John E. Rothwell and

TANK FOR CONTINUOUS AGITATION AND AERATION.

has been used at several mills. It has the advantage of simplicity and of being readily adapted to existing plant. The outlet should be very slightly below the inlet, and, as shown, material can be drawn off from near the bottom of the tank.

Housewarming at the Dome Mill

The 40-stamp mill of the Dome Mines Co., Ltd., was formally started on March 30, though the stamps had been dropping since March 21. The crowds of visitors were taken underground and through the mill, after which the management entertained the party at lunch. On Saturday evening the distinguished visitors were given a banquet at the Majestic theatre, South Poreupine, which was greatly enjoyed. Among the guests were A. Monell, president of the Dome Mines Co., Ltd.; W. S. Edwards, C. L. Denison, Captain De Lamar, John Wilson, W. W. Mein, C. W. Merrill, of the Dome staff; J. L. Englehart, Fred Dane, Denis Murphy, R. T. Shillington, C. B. Flynn, J. H. Black, H. C. Meek, A. T. Cole, Wallace Neshitt, S. B. Clement, W. A. Griffin, and George Lee.

Addresses were made by Messrs. Monell, Merrill, and others. Mr. Merrill announced that it was expected to make a recovery of over 95% of the gold content of the ore. It is reported that the latest results show that this figure has been greatly exceeded and the mill bids fair to establish a record for high extraction. The flow-sheet of the first Dome mill was published in the *Mining and Scientific Press* of May 20, 1911, and during reconstruction after the fire no essential changes were made in the design. The principal features of the mill are forty 1250-lb. stamps, four Pachuca tanks, 8 by 40 ft., Dorr thickeners, and two 76-frame Merrill presses, making a 4-in. cake.

Discussion

Readers of the MINING AND SCIENTIFIC PRESS are invited to use this department for the discussion of technical and other matters pertaining to mining and metallurgy. The Editor welcomes the expression of views contrary to his own, believing that careful criticism is more valuable than casual compliment. Insertion of any contribution is determined by its probable interest to the readers of this journal.

Who is a Mining Engineer?

The Editor:

Sir—The following is a *verbatim* extract from a mine report signed by a man who writes 'E.M.' after his name:

"The quartzite underlying the capping of quartz and now tapped by the No. 6 shaft is finely impregnated with arsenical iron carrying good gold values, very amenable to treatment and will constitute the main bodies of ore in the properties, to what extent they exist in depth may be better assumed as zones, in dyke form, the upheaval and general protrusion of the mountain itself would lead to such a theory, as the fine equal distribution of the arsenical iron with the other minerals on a minor scale contribute, indicate." Also this:

"The values of actual samples taken are in the hands of the assayers as this is written and not necessary to mention at all as far as this report does, my simple duty to speak of it as I found it and to what conclusion to come to." He then concludes by "recommending the proposition as a fine paying investment."

This is not supposed to be a joke, but an actual report that somebody paid for. Is it not about time that the public was protected from this sort of 'flim-flam' and the dignity of the profession also upheld? As it is now, any barber, horse-doctor, or sewing-machine agent can sign 'E.M.' after his name and is, *ipso facto*, a mining engineer.

Spokane, Washington, March 25.

Packing Supplies in Mining Regions

The Editor:

Sir—I was much interested in the article by James Davis, in the *Mining and Scientific Press* of March 23, 1912, concerning packing supplies. His methods are all right, when confined to loads of equal weight, like ore. Then the cross-tree saddle is effective and quickly loaded. But when heavy and uneven loads, especially machinery, has to be packed, the aparajo beats the saddle a hundred times over. In fact, there are many loads of mining machinery, such as sectional mortars, crushers, and fly-wheels, weighing from 250 to 450 lb., which cannot be packed successfully on a cross-tree saddle. The aparajo is somewhat similar to Mr. Davis' pad, made of heavy leather 28 in. wide, its length adjusted to the size of the animal, so that it comes two-thirds way down the animal's side. It is stuffed, from a small round hole, near the top on inside, to near the centre, where it crosses the back, with small fine dried grass, not long or coarse. Saddle blankets are first placed on the mule, the aparajo on top of them, a heavy leather pad over this, then cinched tight. Then load on either side or on top as you wish. If one load is 50 lb. and the other 150 lb., it is quickly balanced, so that they ride even, by raising the heavy load until it balances the light one.

In case it is a heavy or bulky load that must go on top, a small round stick, 3 or 4 in. diam., split as long as the aparajo is wide, with the two ends of each stick tied together with a small string, is placed on either side of the aparajo, one-third way down from the back. This will level up the load, and still keep it low, not top-heavy. Large Saratoga trunks, weighing 300 lb., are packed over mountain trails in this manner. Such a load, if on a platform, built up on top of the cross-tree saddle, would make the load top-heavy, and on a heavy grade throw the animal down the mountain.

I have known a battery cam-shaft made in 1866 and weighing 625 lb., 6 ft. long, to be successfully packed 60 miles, over three ranges of mountains. A wire cable, if over 5/8-

in. diam., should never be coiled and packed as a load on each animal, the short coil necessary breaks and strains the small wires of the cable. Unwind the cable on a level piece of ground, lay it out in a long loop, of such length that the total weight is of proper proportion to the number and character of your animals; this is easily regulated by the number of strands of cable on a side. Tie these strands securely together, with a small wire, place your mules in the centre of the loop, lash the strands as one on either side; the looped ends extending in front and rear of the first and last mules will be stiff enough to stay in place and swing clear. I have seen a 7/8-in. tramway rope, 8400 ft. long, packed in three pieces, over three ranges of mountains, in this manner.

Track-iron and piping, 12 to 16-ft. lengths, with the ends tied together, are packed. Mine timbers and lumber over 10-ft. lengths, if over a rough trail, had better be dragged with one end on the ground. A 3/4 or 7/8-in. lash rope is too stiff and heavy; the Mexican's raw-hide twisted rope is better. In Mexico, probably three-fourths of all freight for the mines is packed; one never sees anything but the aparajo. In fact, where there is occasion to have much freight packed of all classes, only the aparajo is used. They are much easier, safer, and better for the animal; when sufficient blankets are used and proper care exercised the animals can be kept in better condition.

G. L. SHELTON.

Ely, Nevada, March 30.

Tonnage Estimation

The Editor:

Sir—In your issue of February 24, T. B. Greenfield is referred to an article of mine in the same issue for the solution of a problem which seems to have arisen as a result of the application of South African formulae in the tonnage estimation of a Mexican ore. My article contains no elucidation of the problem. The credit for the idea as to the use of the specific gravity bottle in the estimation of classifier tonnage belongs to H. Stadler, whose interesting paper on the subject appeared in the *Journal of the Chemical, Metallurgical, and Mining Society of South Africa*, November 1911.

As a preliminary, may I draw attention to the desirability of a few pointers being published with a reprint of a paper applicable to local conditions only. Mr. Stadler deals with an ore of apparently absolutely uniform composition, and is, in consequence, able to use the determined density of the whole on calculations dealing with any classified portion. Mr. Greenfield's ore, on the other hand, consists of quartz and a large amount of clay and oxide of iron. In endeavoring to find the tonnage of sand passing through a tube-mill, as delivered at the classifier cone underflow, a difficulty is experienced on account of the varying results obtained in the estimation of the density of the ore, due to the presence of the clay. Perhaps it is superfluous to add that calculations of cone underflow tonnage should be based on the density of the ore comprising that underflow, in which the proportion of clay would surely be very small. With an ore of varying density it is difficult to see the advantage of the specific gravity method in the compilation of tonnage figures which are not used in connection with assay returns.

Mr. Greenfield refers to the "varying oxidation of the iron and de-hydration of the alumina" in the ore-density estimation. As the iron has already been reported to be in the form of oxide, it is difficult to see how material change can occur under ordinary conditions. As regards the clay, I presume it may be taken to be an ordinary hydrated silicate of aluminum whose natural water content might be anything from 5 to 15%. The water would occur hygroscopically and in combination, but the temperature necessary to drive off the combined water is so much higher than that required to remove the hygroscopic moisture that there should be no difficulty in keeping the two estimates separate.

In calculating classifier tonnage the need for extreme accuracy is questionable. In most cases, however, tonnage has no significance apart from assay value; and in dealing

with ores carrying a large amount of clay it is advisable to dry the sample for a density estimation at the same temperature as the ore is dried preparatory to being assayed. Too often the density sample is dried with the utmost care at the temperature of boiling water, and the assay sample heated to redness on a hot-plate. A lower density means a higher tonnage; a smaller bulk a higher assay result. Hence an addition to the 'unaccountable' discrepancy occurring at the end of the month.

London, March 12.

The Mine-Owners' Liability for Accidents

The Editor:

Sir—It was a profound change in the status of the law in regard to those who must eat their bread in the sweat of their faces that was made by the enactment by the legislature of 1911, of the Roseberry liability and compensation law. Not since the shackles of slavery were stricken from our black brother of the South has anything occurred that was comparable to it, and it is not flattering to our American vanity to call to mind the fact that, as with slavery, so with the emancipation of industrial labor from the old order, Europe led America in the reform by one full generation of men. What Lincoln was as an emancipator of the black man, Bismarck was as the emancipator of the hurt man, and the world is coming to recognize this as the greatest act of Bismarck's great career.

As far as California is concerned, the old order went out when the Roseberry liability and compensation law went into effect, September 1, 1911, and the new order came in. What the old order was will be the subject of this letter. What the new order is will be the subject for the next. Prior to September 1, 1911, it was the law in California, except as slightly modified by a statute enacted in 1907, that whoever took employment at wages himself assumed all the physical hazards of the occupation, and his employer, and the industry out of which that employer hoped to grow rich, assumed none of them. This was known as the common-law doctrine of 'assumption of risk', and had its origin in a judicial decision rendered in England in 1837, by Lord Abinger, in the case of *Priestly v. Fowler*, growing out of an injury that was suffered through the breaking down of a butcher's cart.

The law in the case was judge-made. No legislature or parliament ever enacted such a law, although nearly all legislatures and all parliaments have been called upon from time to time to mitigate the severities of the law then made by this sleek, well conditioned, periwigged judge while toasting his shins comfortably in front of a blazing hearth in the seclusion of his own chambers. Thus ensconced, this judge gave himself up to the delights of pure reason and so decreed that whoever took employment in a hazardous occupation would naturally demand, and receive, wages proportionately increased according to the hazard, or else he would refuse to work, and that this increase in wages would insure the worker against the consequences of injury. The reasoning of the noble lord was all right, but the facts were all wrong. Except where labor is so thoroughly organized as to be able to compel, through collective bargaining, favorable arrangements as to wages and hours and conditions of labor, the laborer has always had to take the work he could get at such wages as his employer was willing to pay, and some of the most dangerous occupations have been about the most poorly paid. Wise in the law, Lord Abinger was densely, even stupidly, ignorant of the commonest facts of everyday life, and as a result of that ignorance he inflicted upon toiling humanity one of the most grievous burdens that it has been the lot of the children of men to bear. Any workman could have told him better, but it never occurred to him to ask one of them. The relation between employer and employee in those days was that of master and servant, with all the difference in social station that those terms imply, and it had not been twenty years since it was as unlawful for as many as five workmen to assemble together to consider their industrial welfare as

it would have been to plot to blow up a building or hold up a traveler.

The fellow-servant doctrine grew out of that assumption of risk and constituted merely another risk assumed by the luckless employee—that of being hurt through the carelessness of another employee. It was reasoned out in the seclusion of the judicial chambers that if an employee knew that a fellow-employee was careless, he would go to the employer and say to him: "That man is careless; he will be the means of some of us getting hurt some day; therefore if you do not discharge him I will quit your service," and of course the careless workman would be discharged forthwith or the prudent workman would proceed to hunt another job. Again the reasoning was all right, but the facts were all wrong and wholly inconsistent with the common experience of mankind. That is a fault with the law of judicial decision. It does not square with the facts and everyday experiences of life, but goes off into the aerial realm of pure reasoning. As any intelligent workman could have informed the noble lord, accidents through the carelessness of fellow-workmen do not often flow from workmen of known and notorious want of care, but rather from momentary lapses of the mind, wholly unlooked for. Inadvertently one gives the wrong signal, pulls the wrong rope, strikes a glancing blow instead of a direct, and the accident has happened. And yet the hurt workman, hurt through such inadvertence, was barred all recovery from his master, in spite of the fact that the master ever had been responsible to those not in his employ for injuries inflicted by all who were in his employ. If a teamster had run down and injured a workman working for another man, his master would be responsible for his act, but if he ran down and injured one of his own workmen the injured workman could recover nothing from him.

Finally, this august lord of the British bench, superconscious of the great dignity of his office, held that where an injury was caused partly by the carelessness of the employer and partly by the carelessness of the injured employee, the injured workman should have no right of action, no matter how slight the contributory negligence of the person hurt or how gross the degree of carelessness of the employer, and for the reason that so august a personage as a judge could not be expected, where both parties were negligent, to undertake to apportion the degrees of negligence between the parties.

This, then, constituted the old order in relation to the status before the law of those who are industrially hurt, as that law stood in California up to and including August 31, 1911, and upon which California then and there turned its back. These rules came across the seas to us and were imposed upon American labor at the instance of the railroads. The first application of these doctrines was in the case of *Murray v. the South Carolina Railroad*, decided in 1841, and was a three-to-two decision of the supreme bench of that state. It was next applied in the case of *Farwell v. the Boston & Worcester Railroad*, where an engineer was injured through the carelessness of a switchman, the court holding that "justice" and "policy" required that the engineer, and not the railroad company, should assume the consequences of the negligence of a switchman (over whom the engineer had no control), and that "policy" required that assumption inasmuch as it would contribute to the safety of all concerned. A critical examination of the phrenological development on that judicial head should prove of interest to the science of psychology.

Anyhow, one judge followed another in applying these rules, as one sheep may follow another over the wall out of a safe pasture onto a railroad right-of-way, where an express train may presently come along and reduce the whole band into chops, and not until we understand the psychology of the mind of the sheep shall we fully comprehend the mind of the judge who follows precedents unheedingly, no matter where they may take him and those whose rights he thereby wrongs.

A. J. PILLSBURY.

San Francisco, March 25.

Special Correspondence

LOS ANGELES

REPORT OF ORGANIZATION COMMITTEE OF THE MINING ENGINEERS SOCIETY OF SOUTHERN CALIFORNIA.

The committee on organization of the Mining Engineers Society of Southern California, recently formed, as before noted in the *Mining and Scientific Press*, reports that in its opinion the best results will be obtained by placing the technical interests of the society under the control of professional men, selected on their personal and professional record, and inviting the coöperation, as associates, with slightly modified membership privileges, of non-professional men, commercially interested in mining, in oil, in metallurgy, or in mining machinery and supplies, and of suitable persons occupied with business foreign to mining engineering and its allied branches. It points out that there are two classes available for membership: (a) members of the Mining and Metallurgical Society of America, and of the American Institute of Mining Engineers; (b) engineers in good standing who are not members of either body. All of the M. M. S. A. members in Los Angeles and most of the A. I. M. E. members would be eligible. Many not affiliated with either of the older organizations will be led to seek membership through interest in the M. E. S. S. C., while others would become members of the last, but would not care to join either of the older bodies. While it is believed that most of the members will be drawn from Los Angeles and tributary districts, no geographic limitation need be placed on membership. The committee reiterates that one of the chief needs is for a technical library and reading room.

An initiation fee of \$10 and dues of \$2 per month for members who have places of business in Los Angeles, or within 100 miles, are recommended by the committee. An initiation fee of \$5 and annual dues of \$10 are recommended for members outside of the boundaries named.

In regard to affiliation with the A. I. M. E., discussion concerning which was reported in the issue of this magazine for February 10, the committee states:

"The following reply, in a letter from the secretary of the Institute, dated February 20, has been confirmed by a committee report to the Council of that body under date of March 23:

"The Council approves in general of the organization of a local, or geographical section of the American Institute of Mining Engineers, but under the constitution and by-laws, the organization must be effected in the first instance in harmony with the present rules of the A. I. M. E.

"The Council believes, however, that the wishes of the Los Angeles members of the Institute can be met by giving the proposed organization the greatest possible measure of Home Rule under the rules of the Institute.

"The Institute cannot approve of any independent assessment for dues, but sees no objection to voluntary contributions to be supplied at the discretion of the local organization to the local needs.

"It occurs to us that possibly the organization of a library, on an independent basis, would meet the question of additional dues from the local members."

"From this reply it is evidently necessary to form an independent society to support the library and reading rooms, for the reason that a library cannot live without an income, while the rules governing sections of the Institute forbid raising money by assessment and permit only voluntary contributions. Further, in such a section, all members and associates of the Institute would have equal membership privileges and persons not members of that organization would not be recognized."

In order to give all possible support to the A. I. M. E. and to assist in any needed reform, the committee advises members of that body resident in and about Los Angeles to form a section, and suggests that a section of the M. M. S. A. would be desirable. Owing to the difficulty in keep-

ing up interest in meetings held for the reading of papers, it is suggested that such meetings are unsatisfactory without facilities for publication, and that publication is best left to a national organization or to leading scientific journals.

Further plans deal with the possibility of forming a general technical library through coöperation with the civil, mechanical, chemical, and electrical engineers, and with the Chamber of Mines and Oil.

One prospective member of the new organization has promised \$500 in cash toward the proposed library, and others have agreed to assist. An initial membership of at least 50 is desired to provide an income of \$100 per month for maintaining the rooms and library. All mining engineers entitled to receive a copy of the committee's report who may have been omitted from the mailing list, are invited to notify the committee, which includes F. J. H. Merrill, chairman, E. Call Brown, T. B. Comstock, C. Colcock Jones, E. A. Montgomery, and W. F. Staunton.

KALGOORLIE, WESTERN AUSTRALIA

CYCLONE DAMAGE.—JANUARY DEVELOPMENT.—COLLIE COAL-FIELD.—PRODUCTION FOR MONTH.

Eight years ago a very destructive cyclone occurred in this district, and almost every year since we have had one in a mild way, but on February 5 a 15-minute blow visited us again and did a lot of damage generally. The worst feature of the affair was that the Power company's mains, which carry power to many of the mines, were blown down, while its cooling tower for the condensing plant was smashed. The Associated, Horse-Shoe, and Ivanhoe have their own complete generating plants. The Lake View &

GOLDEN HORSE-SHOE MINE.

Star and Oroya Links have part stand-bys, while the Kalgurli, Great Boulder, Perseverance, and South Kalgurli depend greatly on the Power company. The Associated Northern and Hainault use only a few small motors, which do not affect work much. The Horse-Shoe has power to spare and is supplying the Boulder; but the Kalgurli expected to be in operation a week after the cyclone.

The month of January has been quiet. Developments may be chronicled as follows: The Horse-Shoe, at 2800 ft. from the Boulder main shaft on No. 4 lode, drove 5 ft., where the lode was 15 ft. wide, the ore averaging \$30 per ton. The progress reports from the Boulder, Ivanhoe, Lake View, and Kalgurli are of a satisfactory nature, yet the lower levels in most of them are poor. The Perseverance is re-centring and skidding its main shaft, which has given trouble of late, and is installing two-ton skips, which are made at the mine. The plant will run at about 450 tons daily capacity in the meantime, ore being hauled through No. 6 shaft. The Associated has stopped work at its No. 20 level, the ore being of low grade. The Chaffers is practically closed down, the reserves being given as 104,900 tons, worth \$6.90 per ton. The problem is whether to remodel and enlarge the dry-crushing plant to a capacity of 6000 tons per week, so as to give a profit of 60c. per ton, or leave it alone. The Bullfinch main shaft is down to 333 ft. The latest development in a winze at a depth of 50 ft.

below the 100-ft. level shows a lode 31 ft. wide averaging \$25.50 per ton. The boilers, hoist, and head-gear are in position. The Sons of Gwalia is diamond-drilling on the seventh and fifteenth levels. The Lady Miller at Norseman is being equipped with a new plant. The North Kalgurli report shows that during the past financial year tributers crushed 10,209 tons valued at \$160,000. This was from ore between the fifth and sixth levels. The gross profit to the company was \$19,300. Since 1907 \$82,000 has been paid in royalties by tributers. The option on the Gimlet mine at Ora Banda was dropped by the Gwalia South company, the ore being too low grade and hard. The Gimlet S. Extended has stripped its shaft in preparation for skips and a 350-ton daily capacity. During the past six months a party had a tribute on the Oroya Links and finished the term last month, four men netting \$22,000 each.

The tributers at the Golden Pole, Dayhurst, up north, made a profit of \$2000 each in 11 months. During 1911 the Dundas goldfield returned 28,665 oz. bullion from 38,037 tons treated, also 320 oz. from alluvial workings. The inspectors for the districts named report that in 1911, in the Menzies district, mining has not been satisfactory; while centres between there and Kalgoorlie, some eighty miles, a depression existed. Other districts near showed fair results from a good deal of prospecting. Mount Ida had little development done, although the country would repay prospecting. Other places are quiet on account of no water-supply. A few gas engine and Huntington mill plants are working in these parts. The Kanouna district was quiet, although of late active exploratory work has been undertaken in old mines.

The Collie coalfield produced only 249,784 tons during the year, or 11,800 less than in 1910, on account of strikes. There are 6 mines at work, which produce from 2913 to 89,227 tons annually. There were no accidents among the 477 men at work, while the output was 523 tons per man. The two Holman pneumatic stamps on the Mountain Queen, at the Southern Cross, are doing good work, each crushing about 70 tons per day. The new 20-stamp mill, with tube-mill and vacuum plant, on the Yuanmi is at work, and the output should soon be announced. The Richards classifier at the Hainault is good, and takes the pulp from 40 stamps, delivering a clean classified product.

The new mill at the Bullfinch will consist of a crusher, 20 stamps, tube-mill, agitators, and three Ridgway No. 3 style machines, all motor driven. It is to be ready in August. The ore is expected to average \$10.50 per ton. The use of the new Ridgway machines increases, and at present the Boulder has two, the St. George one, on a kaolin ore, the Ora Banda three, and the Bullfinch three, while it is known that one or two of the Kalgoorlie mines view the machines favorably. Mechanically it is good and the washing leaves low soluble gold. The increase in value of wash solution is exceedingly low, when compared with other vacuum systems. On roasted ore, one machine can treat 350 tons per day, and on a soft oxidized ore, or kaolin matter, about 120 tons. The old-style Ridgways are apt to be superseded.

For examination of engine-drives in Western Australia, the Minister for Mines has formed a traveling board of examiners who will hold the quarterly, half-yearly, and yearly district examinations. Ambulance classes have been started for the mines and are being well attended. Already the mines have a number of good first-aid men, and, of course, the properties are fully equipped with accessories to be quickly available in case of serious accidents occurring.

In the December number of the Chamber of Mines Journal, W. R. Degenhardt discusses gas engines at the Sons of Gwalia. This mine is 1250 ft. above sea-level. The tests were on a 167-b.h.p. coupled engine of Crosby make, with cylinders 17 by 24 in. by 190 r.p.m., driving by belt an A. E. G. generator of 112 kw., 550 volt, 3 phase, 40 cycles driven 800 r.p.m. The useful work totaled 24.5%. Fuel per horse-power, 0.96 lb. charcoal. Cost per brake-horse-power, 1 cent.

The January gold output was valued at \$2,255,000, the principal returns being as under:

Name.	Tonnage.	Yield.	Profit.	Divid'd.
Associated	10,193	\$72,500	\$6,100
Burbanks Main Lode...	1,641	18,000
Golden Horse-Shoe	23,264	164,000	10,000
Golden Ridge	2,817	27,000	8,500
Gt. Boulder Perseverance	19,681	113,000	15,500
Gt. Boulder Proprietary	17,535	245,000	132,500
Great Fingall	5,685	60,000	12,000
Hainault	5,639	34,000	50
Ivanhoe	20,102	204,500	90,000	50,000
Kalgurli	10,630	108,000	45,000	24,000
Lake View & Star....	18,060	105,000	17,800
Oroya Black Range....	4,700	47,000	16,500
Oroya Links	11,000	64,400	9,700
Sons of Gwalia South..	2,456	15,400	3,700
South Kalgurli	9,600	60,100	9,700

FAIRBANKS, ALASKA

DISTRICT DEVELOPED WITHOUT OUTSIDE CAPITAL.—MANY PROMISING CLAIMS.—MINE NOTES.

That this district bids fair to be self developing is shown by the large number of shipments to the local mill. Most of these are from prospects that have no financial backing as yet, and which must depend on the ore taken out to carry the burden of development. Although this is not true in every case, the large proportion of self-supporting prospects is remarkable.

A shipment of 2 tons from the Otto Nars property on Fairbanks creek, returned \$60 per ton in free gold, no attempt being made to save concentrate or to test the tailing. This is the first shipment from the claim. Following the satisfactory mill test on ore from the Hudson brothers' property on Ester creek, a larger shipment, of almost 50 tons, is being sacked. The vein is over 5 ft. wide. It is probable that a small mill will be built this season. At present, the local mill in charge of Lon Freestone is crushing 13 tons of ore from the Overgaard lease at the head of Willow creek. The rock should return \$50 per ton, by conservative estimate. This property is now owned by the principal stockholders of the Newsboy company, which recently bought it from Herseherberger & Buell.

Development is being carried forward on the Newsboy property with all possible speed. The 215-ft. level development is on contract while the regular crew is sinking the shaft to the 315-ft. level. Considerable trading in Newsboy stock has been going on lately. Several blocks of promotion stock have been taken at 35c. The par value is \$1 and the capitalization is \$320,000. There is a 5-stamp mill on the property. The undoubted integrity of the controlling stockholders is an argument in favor of the investment. Were this camp closer to financial centres, a flurry in this stock would undoubtedly occur.

A two-ton shipment from the Utigaard-Nehrland lease has just been crushed by the local mill. Returns show content of \$30 per ton. Shipping will probably be discontinued till a customs mill can be erected at the mouth of Chatham or Wolf creeks. Fourteen tons of ore from the L. J. McCarty property at the head of Wolf creek, was put through recently and \$60 per ton in free gold was recovered. The shaft on the Fredrich property on Vault creek, is down 275 ft. The installation of the small 3-stamp mill on the Reliance M. Co.'s ground at the head of Dome creek, is nearly complete and Mr. Spaulding, the manager, expects to begin crushing soon. There is plenty of water in the mine to supply the mill. Only the highest grade ore will be milled, the lower grade being put on the dump for future treatment with a larger mill.

It is reported that W. B. Vanderlip will start soon on a trip to Ruby and the Koyukuk to examine some properties. Development on the large Treasure creek antimony vein will be continued while he is absent. Braumbaugh & Hamilton are working at present on a 5-stamp mill for McGillivray & Fisher, who are operating a lease on the News-

boy Extension. A hoist will also be installed as soon as the 100-ft. shaft shows a good sized vein. Keffler & Oedekoven, lessees on the Jupiter-Mars property, on Chatham creek, are now driving along a vein that shows a width of close to 20 ft. While the ore is not valuable enough to permit shipping, a mill on the ground should show a profit. The Jupiter-Mars property consists of a group of 11 claims between Chatham and Wolf creeks, on a line between the Rhoads-Hall and Rexall claims. Tests, run from smaller veins on these claims, have shown ore valued at \$30 per ton. Several men are working at present on the Rexall claim, on which Mr. Cooper holds a lease. Two 10-ton shipments were made last month, one returning \$170 per ton and the other \$65 per ton. Jesson brothers are still driving along the vein on their property at the head of Chatham creek. A new vein has been found on Fairbanks creek on the left limit claims of Cook brothers. Since the shaft on the Hess & Thompson property has been completely retimbered, the owners have been engaged in development. It is doubtful if any large shipments will be made, it being the intention to install a small mill this summer. Birch & Anderson, of Granite creek, have a three-ton shipment awaiting treatment at the local mill. Sumner S. Smith, mine inspector for Alaska, recently paid his first visit to Fairbanks. It is Mr. Smith's intention to pay a longer visit during the open season this summer. E. R. Peoples will soon try out a Straub rapid-stamp mill, made in Oakland, California. The process uses electrolytic amalgamation.

With the number of excellent prospects being opened up, and several mills crushing on proved orebodies, this season should show a marked increase in activity among the quartz miners. Competent judges of the placer outlook predict an output for the Fairbanks district as large or larger than that of last year.

NEW YORK

MARKET CONDITIONS MUCH BETTER.—COPPER SITUATION.—
CALUMET & ARIZONA PROFITS.—MASON VALLEY PLANS.
—PORPHYRIES AVOIDING OVERPRODUCTION.

It has been many weary months of waiting for Wall Street; months of depression and stagnation that seemed never ending. The tide apparently has turned, and it requires all of the comparisons that are familiar in describing a hearty welcome—the flowers in May—the sight of land—the hand held out to the drowning man—to do justice to the reception that traders are giving to the coming and increasing business. The present turn to activity and million-share days is an instance of the domination of psychology over fundamental conditions. As some one said of the game of golf, the condition of the market is a 'state of mind.' To find any logical reason for market advances and brisk trading by way of comparison with what has gone before would be exceedingly difficult. Just now the swing is upward, the sky is all rosy, and it is unjustifiably pessimistic to call attention to the fact that not one of the obstacles in the way of a return to business activity and an era of constructive enterprise has been removed.

In a way the copper situation has been the leading factor in the recent betterment, and the cutting down of accumulated stocks to a point where there is no more than a safe working balance on hand is the one argument that is never overlooked among the various causes mentioned as responsible for the recent market upturn. Realizing that uncertainties are always more alluring than certainties, the leading operators in the copper share market and those who are behind what is evidently a concerted move to distribute stocks are talking much of increased dividends possible in the coppers, and pointing to the added incomes that will be received from 15c. copper.

Amalgamated, which is leading the advance in the copper list, is much discussed in regard to dividend possibilities. The Anaconda-Amalgamated organization is so involved that the ordinary trader tires and quits before achieving any real analysis of the relative positions of the two concerns, and as a result that attitude of the public is to treat Amal-

gamated, which is the market favorite, simply as a gambling counter. It is stated, however, upon apparently good authority that the two companies can show combined cash assets of about \$40,000,000 and that there will soon be something of a melon to cut by the Anaconda, which will in turn be distributed to Amalgamated shareholders. There is some talk of a coming move to retire the stock of the Amalgamated Copper Co., by a distribution in exchange of Anaconda, on the basis of two shares of the latter for one share of the former. Should this be done it will be the end of one very vivid chapter in American affairs; a chapter embracing mining, high finance, state and national politics. Fiction hardly holds a more thrilling story than that of Amalgamated, and it will never be written in all of its devious interwinings, nor will there ever be compiled a complete chronicle of the men it made and unmade in Montana, in Boston, and in New York. The day for such happenings has passed, but the future will hardly hold any more interesting important series of events, in any more picturesque setting or with actors of greater power than those who battled for supremacy in Butte.

OHIO COPPER CO. MAIN MILL BUILDING.

Rehabilitation of the Calumet & Arizona seems to be complete. It is producing 50,000,000 lb. of copper per year and at a cost of 7.34c. per pound. There is but one large producer that succeeds in reaching a lower figure, the Nevada Consolidated. On 15c. copper this means that the company is making a profit of 50% on its output; with earnings equivalent to about \$6.50 on the company's outstanding stock. One of the most important strikes ever made by the company was made recently when an orebody was opened on the thirteenth level, in a cross-cut from the Briggs shaft. The ore is sulphide and runs from 22 to 41% copper.

The Mason Valley smelter at Yerington is reported to be doing a largely increased custom business. The Mason Valley property belongs to the family of which Inspiration Consolidated is the head, and if production justifies increasing smelter capacity, the present plant will probably be the nucleus for a much larger smelter. It was reported recently that the Thompson-Gunn interests, which control the Mason Valley, were considering the purchase of the Ohio Copper and that Henry Krumb was making an examination of the Ohio in this behalf. It is now stated officially that such is not the case.

It is not so long ago that the greatness of the porphyries was supposed to lie in the enormous production of which they were capable. Now, however, it is apparently considered not good taste to allude to overproduction as a possibility, and the argument is advanced as to Utah Copper and Nevada Consolidated, that, on the present market, these properties are steadily accumulating a surplus, and from a managerial standpoint there is no necessity of increasing production. From the standpoint of the shareholder, whose interest should certainly be much ahead of all other considerations, there can be no excuse for holding back production. The shareholder has an investment, against which interest charges accumulate steadily, his dividends represent return of both interest and principal and the sooner his

investment is liquidated the smaller is the proportion of the total amount received which is required to be charged off as interest. The price of the metal being satisfactory, the stockholder has every right to insist not only that hay shall be made while the sun shines, but that the more hay the better.

The United States S. R. & M. Co. is able to show exceedingly satisfactory profits for January and February of the current year, notwithstanding the disturbed conditions in Mexico. The milling plants handling the ores from the Real del Monte and the Pachuca mines have been brought up from 600 tons daily capacity to about 1100 tons. This fact, coupled with the improved price of silver, has added materially to the company's earnings.

The interest in the Nevada precious metal stock continues to run high. West End is the favorite among the Tonopah issues and many thousand shares are being traded in daily. Atlanta and Goldfield Belmont are leaders among the Goldfield issues. While trading has been confined largely to professional operators, there is undoubtedly a growing public coming in.

W. A. Paine, of the Boston house of Paine, Webber & Co., is said to have become heavily interested in Tuolumne, one of the rich little properties of Butte, and is also said to be considering a deal for a large interest or the control of the Pilot Butte, which is a neighbor of the Tuolumne and controlled by the same interests. There has been at times some talk of a consolidation of the two properties mentioned and the Butte-Ballaklava, the three properties to make an independent producer large enough to have some voice in mining circles at Butte.

The Miami Copper Co. has declared its initial dividend of 50c. per share, thus being the first of the new porphyry group to make a distribution of earnings. Ahmeek, the big new producer of the Lake Michigan copper district, has increased its dividend and is now on a basis of \$4 per share quarterly. The initial dividend paid one year ago was \$2 per share, while the disbursement of three months ago was \$3 per share. Ahmeek is traded in on the Boston Curb, not being listed on the Boston Exchange, as are most of the Lake coppers, and is selling at nearly \$300 per share. North Butte has made a like proportionate increase, the recent declaration being 40c. per share as against 30c. three months ago. Greene-Canaana is said to be on a basis where it can earn more than \$1.25 per share and that the present dividend rate of 50c. will in all likelihood be doubled in the near future. Utah Consolidated, which has been through some considerable difficulty during the past eighteen months, has just declared a dividend of 50c. per share. This property has become more of a lead producer than a copper property and in the development work during the year the lead orebodies were the most important opened. Over and above all—and by far the most important from a market standpoint—is the Anaconda-Amalgamated. Anaconda and Amalgamated are each paying \$2 per share yearly. Anaconda is said to be earning more than twice its dividend, and Amalgamated is said to be disbursing less than one-fourth of its receipts. It is said that the former is possessed of a cash reserve of \$27,000,000. All of which is by way of invitation rather.

An issue which is about to be offered to the public in a larger way heretofore is the Guggenheim Exploration Co., which now has its press agents calling attention to the assets piled up in the company's treasury, in the shape of holdings in Utah Copper bought some years ago at low prices, and which is nearly all clear profit now. It is stated that just before the recent rise in Smelters, the Exploration company bought a large block of stock at an average of \$70. The Guggenheim Exploration shares are to be listed on the New York Stock Exchange, but the par value is to be reduced to \$25 by issuing new stock in exchange for the old on a basis of four shares for one now held; the object being to make the issue less unwieldy. At present figures, a hundred shares of stock comes to \$22,000, a price that does not look very attractive to speculators as it ties up too much capital. By way of further market news it may be said that Utah Copper has been selling at \$100 per share; some large holder is stated to have been liquidating

holdings around \$60, selling in 5000 share lots. Underground work in the Boston ground of the Utah Copper has ceased, as the miners have struck for an increase of pay to \$3.50 for miners and \$2.75 for trammers.

NIGERIA

TIN COMPANIES ATTRACTING ATTENTION IN LONDON.—
HISTORY OF DEVELOPMENT.—THE NIGER COMPANY.

The rapid extension of tin mining in Northern Nigeria has provided almost the only outstanding feature of interest in the London mining market recently. February, in fact, was marked by a boom in the shares of tin companies formed to exploit the Northern Nigerian field. This interest has been a long time developing, and even now it may not be stated with any certainty that Nigerian tin mining has a great future. Yet companies are being floated now almost daily and some surprising and informative reports are being issued. The tin is found on the Bauchi field, and probably fifteen million dollars of capital is now invested in that region. The country a few years ago was a savage wilderness. Lying a long way in the interior and reached originally only by a long journey up the Niger river, and then by bush tracks for some 100 or so miles farther, the question of transport stood well in the way of effective development.

Tales of the stanniferous wealth of the country came down for a good many years before anyone paid attention to them. Eventually a little gold mining company, formed to exploit ground afterward proved to be worthless near the West African coast, wound up its affairs and resolved, in answer to these reports, to embark its remaining capital in an attempt to get tin from the interior. This was about two years ago and the results were so good that the attention of many other mining men was soon directed to Northern Nigeria. Prospectors and claim hunters began to make their way into the interior. The British Colonial Government in charge of the territory was determined not to allow anything in the way of improper working or the spoliation of the British investing public so far as lay in its power. For every claim taken up the lessee had to show so much definite cash capital for the working of it. This prevented the straw promoters from playing some of their usual games, and the development of the country, while being slow, has been more solid in consequence. The first definite sign of serious attention from wealthy mine owners came when important Rand houses began to inquire after claims on the Bauchi plateau. Throughout last year the attention given to Nigeria gradually extended, although very few companies so far have become producers. At the end of February there were one dozen companies producing from 6 to 50 tons of tin concentrate per month, the total January output being 202 English tons. Now the formation of companies is proceeding rapidly.

Expectations have been aroused from time to time that an extensive tin-bearing lode in the new field would be discovered. As far back as 1908, at the annual meeting of the Niger company, which was the concern originally having chartered rights over the whole of the two great districts now known as Southern and Northern Nigeria.

The Niger company originally held complete commercial and administrative rights over the whole of Nigeria, just as the Chartered company did over Rhodesia. As the country was developed, however, it parted with its administrative and political rights, retaining only its commercial ones. The company, of course, owns considerable areas in the tin districts of Northern Nigeria, and has been selling portions of the mining rights. For example, in the accounts for 1910, submitted in July last, there figured "special receipts from sales of mining concessions, together with the profits of tin working, \$629,055." If, therefore, the industry is to develop, as some authorities believe, the Niger company will benefit materially. It will be able to obtain higher prices for its mining rights, which may rep-

General Mining News

ALASKA

JUNEAU

(Special Correspondence.)—The Alaska-Ebner Gold Mines Co. has been placed in the hands of receivers. This concern was formerly known as the California Nevada Copper Co. The moving spirit was F. L. Underwood, who was at one time and another connected with the Ely Nevada Mines Co., the British Columbia Copper Co., and other promotions. The California Nevada company acquired an interest in the Ebner mine at Juneau, which was described as a second Alaska Treadwell. A campaign was carried on for more than two years in an endeavor to raise capital through the sale of bonds, but the company was never able to fully finance itself, and the receivership resulted.

Juneau, April 3.

The Alaska Mexican G. M. Co.'s report for February shows that the 120-stamp mill crushed 18,606 tons of ore, the concentrate production being 431 tons. The gold and concentrate production was given as \$54,527, 'realizable value.' Operating expense was \$32,332 and construction expense \$4059, leaving a net profit, estimated, for the month, of \$18,136.

The Alaska United G. M. Co. reports that the Ready Bullion 120-stamp mill in February crushed 17,220 tons of ore, from which 472 tons of concentrate was obtained. The total production was valued at \$44,832, 'realizable value.' Operating expense amounted to \$22,592 and construction expense to \$2219, leaving an estimated net profit of \$20,021. The 700-Foot claim 120-stamp mill crushed 18,564 tons of ore, from which 377 tons of concentrate was obtained. The 'realizable value' of the total production of gold and concentrate was placed at \$45,428. Operating expense was \$25,844 and construction expense \$3191, leaving an estimated net profit of \$16,392.

KETCHIKAN

The Londevan adit has intersected the orebody about 200 ft. from the portal. The ore is silver-lead and contains some gold and silver.

SEWARD PENINSULA

The 1912 All-Alaska sweepstakes was won by A. A. ('Scotty') Allan, driving Mrs. C. E. Darling's team of malamute dogs, in 87 hours, 32 minutes. The race was one of the hardest in the history of the sweepstakes. O. Blatchford, driving the Oliver dogs, was lost for three hours in Death Valley, blinded by a storm. Allan was hard pressed, excepting for the last 50 miles. Alexander Holmson, driving John Johnson's Siberian wolfhounds, holder of the record time, 71 hours, 14 minutes, 20 seconds, got second place. Allan and the Darling team won the 1908, 1911, and 1912 races and made second in 1909 and 1910 events. The purse this year was \$5000. Charles Johnson, driving Fox Ramsey's dogs, arrived third, half an hour behind Holmson, who was half an hour behind the winner. The last team, the Oliver dogs, was in poor condition and hopelessly outdistanced. Mrs. Darling, of Berkeley, California, has announced that her team has been withdrawn from further contests. The dogs will be exhibited at the Panama-Pacific Exposition in 1915.

THE TANANA

Pat O'Connor and associates have found rich ore in the Wild Goose association claim at the head of American creek, in the Hot Springs district. The three-stamp mill on Garden Island, says the *Fairbanks Times* of March 18, has crushed 75 tons of ore since it was started, after a long period of idleness, on December 13. L. A. Freestone is in charge of the mill.

C. P. Guis recently had the 60-hp. boiler formerly used by Peterson & Kellum erected on the Twin creek discovery claim. As the gravel did not yield a profit by hand-work, he is to use machinery in development this summer. A report from Cleary City states that the Homestake property,

Wolf creek, has found a new vein 575 ft. from the portal of the adit.

ARIZONA

COCHISE COUNTY

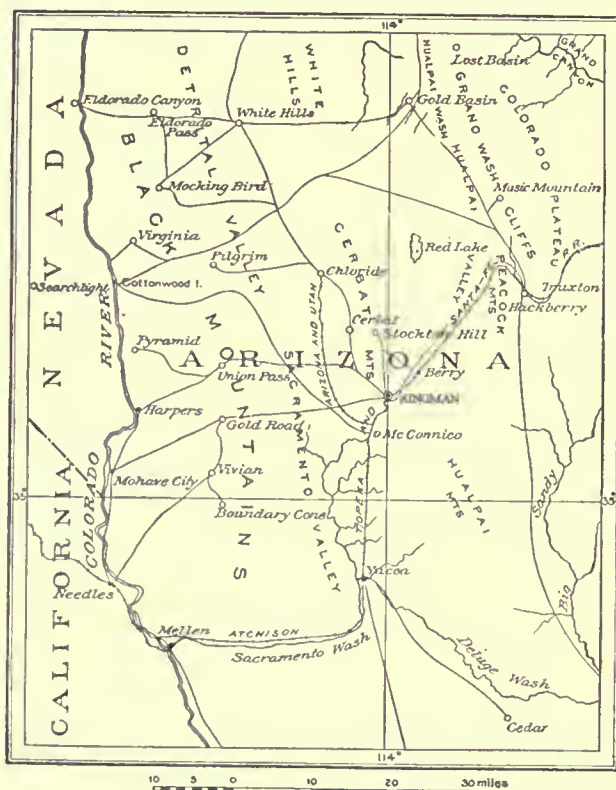

(Special Correspondence.)—Phelps-Dodge negotiations with the Shattuck-Arizona are still pending, but it is said that the Shattuck interests are demanding quite a little more per share than the Copper Queen people are willing to pay. In the meantime the Shattuck is shut down and the recently drawn plans for a smelter are held in abeyance.

Bisbee, April 7.

The Leadville M. Co. has discovered good shipping ore in a raise from the 200-ft. level of its Maid of Sunshine property. Daniel Brown and brothers, owners of the Ontario claim, have a carload of high-grade ore ready for shipment.

GILA COUNTY

(Special Correspondence.)—Churn-drill hole No. 2 of the Southwestern Miami Development Co. is 1070 ft. deep and still in the chalcocite ore it cut at 945 ft. Hole No. 3

PART OF WESTERN ARIZONA.

is 520 ft. deep in the schist formation. Progress has been slow on account of caving. The two new drilling machines have arrived and two new holes will soon be started. Churn-drill hole No. 2 on the Barney group is 420 ft. deep. A road is being built to the place where hole No. 3 will be drilled at the apex of the Live Oak, Southwestern Miami, and Barney properties, the expense to be shared equally by the three companies. At the Inspiration the experimental mill has been started again and J. M. Callow is conducting another set of tests. The trestle connecting the portal of the main adit with the site of the new steel warehouse is nearly completed. E. M. White, formerly manager for the Warrior Copper Co., has been appointed manager for the Manitou Copper Co. operating the Five Points mine 15 miles west of Globe. The present work consists of sinking the Cracker Jim shaft, which is now 130 ft. deep.

Globe, April 4.

Miami Copper has declared a quarterly dividend of 50c. per share, placing the stock on a \$2 basis. It is scarcely more than a year since Miami started the first unit of its concentrator. In eight of the twelve months since its mill was placed in operation, copper has averaged about 12¼c. per pound.

MOHAVE COUNTY

Lyon Kay has discovered a vein containing copper, gold, and silver between the Keystone and George Washington mines, at Mineral Park, says the *Mohave County Miner*. For 18 in. the ore is reported to have assayed \$7 per ton gold and silver and 41% copper. The Frisco M. & P. Co. as the result of a ten days' run at the mill has sent to the mint a bar of bullion valued at \$6500. F. H. Summeril and Frank Duden report the discovery of good tungsten ore on their property, east of Yucca. The Arizona Alpha M. Co. has had 500 tons of ore from the Alpha mine concentrated at Needles. The results have not been announced, but it is rumored that the concentration was at the rate of three and one-half tons to one, and that the concentrate is valued at about \$80 per ton. It is believed that plans are made for building a mill. O. F. Brinton is superintendent of the property. The Oro Plata recently sent 30 tons of concentrate to the smelter.

SANTA CRUZ COUNTY

It is reported that the Shannon Copper Co. has purchased the R. R. R. mine near Patagonia, and will develop the property on a large scale. Rich ore was discovered there recently.

YAVAPAI COUNTY

High-grade ore was found recently in the Bannie Mines Co. property, states a Prescott report. Litigation which has involved the property for many years has been settled for some time, and it is rumored that sufficient money has been raised to insure the resumption of development. E. A. Rogers is president of the company. It is reported that a new mill is to be erected on the Independence group of claims, owned by J. A. Forbes and associates.

CALIFORNIA

Articles of incorporation for the Prospectors' Alliance of America, organized recently at a meeting at Bishop, have been filed at Sacramento. Among the incorporators is T. L. Oddie, governor of Nevada. There is no capital stock. The incorporators are: J. A. Butler, Sacramento; Tasker L. Oddie, Carson City, Nevada; Eugene Grutt, Hawthorn, Nevada; Lester C. Hall, George W. Leedy, A. H. Swallow, and C. E. Kunze, all of Bishop, California.

AMADOR COUNTY

(Special Correspondence.)—Thirty stamps of the Central Eureka mill are dropping on ore from the 2600 and 2800-ft. levels. On the 2700-ft. level an eight-foot ore-body has been intersected by the south drift. Arrangements are under way to open this vein on the 2800-ft. workings. J. E. Davis is manager of the property. The shaft at the Plymouth Con., otherwise the Empire-Pacific, has been unwatered to the 500-ft. level. The old timbers are said to be in good condition, and it is expected the shaft will be easily placed in shape for development work. The Hardenburg shaft is near the 800-ft. point and will be continued probably to a depth of 1500 ft. Work is about to start on a head-frame at the South Jackson. It is expected to have a new plant of machinery in position and 40 men employed within 30 days. San Francisco capitalists are principally interested in the company, of which Jeffrey Schweltzer is president and manager. A rich gravel strike is reported from the Grillo property, in the Volcano district.

Jackson, April 8.

KERN COUNTY

(Telegraphic Correspondence.)—The California oil companies during March paid an aggregate of \$745,842 in dividends. To this amount should be added \$80,000 paid in dividends by the Mexican Petroleum, Ltd., making a total of \$825,842.

L. P. St. Clair, president of the Independent Oil Producers' agency, reported yesterday at the annual meeting of that organization here that contracts for more than 52,000,000 bbl. of oil are on hand. The requirements for these contracts will be about 60%, or more than 31,000,000 bbl. The storage price to the agency for the year was 35.7c. per

bbl., and the net price 31.97c. The oil handled during the year amounted to 24,132,709. Deliveries, principally to the Union Oil Co., amounted to 14,004,102 bbl. The total net sales amounted to \$4,940,887.

Bakersfield, April 11.

The Red Dog mill cyanide plant is again in operation, after a shut-down of about two years. Frank Howard has obtained a bond on the Manuel Rodgers property, in the Argus range district. The price given in the bond is \$30,000. The Yellow Aster M. Co. has a \$26,000 gold bar as the result of a clean-up from mill No. 1.

NEVADA COUNTY

The report of the North Star Mines Co. for the year ended December 31 shows a production in that period of \$1,025,088, on which the net profit was \$468,651. For purchase of property and development of the Cincinnati Hill mine the company spent \$58,065, leaving a balance of \$410,616. Income from invested funds and other sources brought the total net receipts to \$452,890. The company paid in dividends during the year \$425,000. It has an option on the Champion group at Nevada City.

PLUMAS COUNTY

Exceptionally rich ore has been discovered in the Gruss mine at Genessee at a depth of 175 ft. W. H. Draney and associates of Greenville are planning to develop several claims south of that city. A rich vein containing copper and gold has been cut in the Engle mine, near Taylorville, in the Greenville district.

SANTA CLARA COUNTY

B. L. Barney and J. W. McCord, representing about 25 former stockholders in the Lost Hills M. Co., have brought suit at San Jose against J. D. Martin and William Lindemann to recover \$104,700. The plaintiffs state that Martin and Lindemann told them of a man who was willing to pay \$5 per share for the stock, and the stockholders indorsed their 34,900 shares, all that had been issued to that time, to the defendants. The stock, it is asserted, was sold on March 28 to George E. Cameron for \$8 per share, of which \$5 per share was turned over to the members of the pool. The latter are suing to recover the remaining \$3 per share.

SIERRA COUNTY

(Special Correspondence.)—Stockholders of the Rio Antigua M. Co. have purchased the stock of the South Fork M. Co., owning the South Fork mine, near Forest. The Rio Antigua people have operated the placer deposits under bond and lease for about eight years, their work being principally confined to search for the south extension of the Bald Mountain channel. Occasional streaks of rich gravel have been uncovered and five quartz veins intersected. Under the new arrangement the attention of the company will be largely concentrated on the development of the quartz resources. These are thought to be extensions of the Tightner-Rainbow-Red Star vein-systems. It is reported that electrical machinery will be obtained. Los Angeles investors are backing the company, for which Fred W. Kuhfeld is manager. San Francisco people have taken a bond on the Hayes Con. group, near Sierra City, of which Thomas C. Heide is now superintendent. The 10-stamp mill is running steadily and it is rumored the management plans to enlarge it this summer. It is reported operation will be resumed at the Phoenix mine, Sierra City district, of which A. Wise is manager.

Downieville, April 6.

COLORADO

GILPIN COUNTY

Fred Berger and Robert Sayre of Denver have taken over the Phoenix-Burroughs, Conlee-Burroughs, Kansas-Burroughs, Pease-Kansas, University-Kansas, Monroe, and other nearby claims. It is reported that they will start development on a large scale. The properties are in the Nevada district.

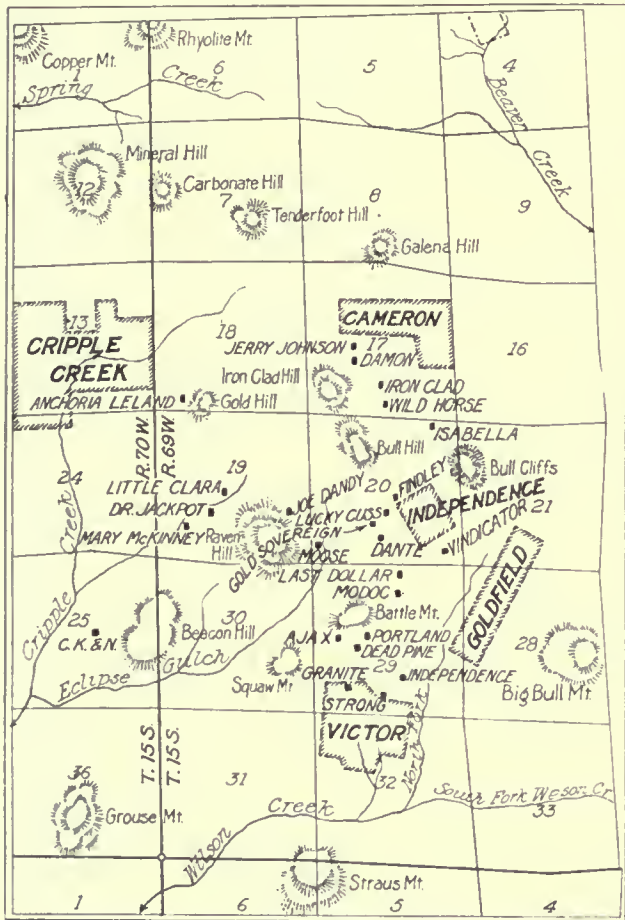

TELLER COUNTY

The Crystal Peak Gem Co., of Cripple Creek, has filed

on seven placer claims in the Crystal hills, about seven miles north of Florissant. There are eight locations, each claim being for 160 acres, on the basis of 20 acres per locator. The Vindicator Con. G. M. Co. in March produced 130 ears of ore, of which the company itself shipped 82 ears, the largest output for the company in the past two years. The Vindicator company, it is reported, will pay a dividend of 3c. per share on April 25, to stockholders of record April 15. The El Paso mine in March shipped 100 ears of ore. The Lady Campbell G. M. Co. has sunk its Emma Abbott shaft to 130 ft. and will start a drift under the main orebody.

The Blue Flag G. M. Co. will use the cyanide process in its mill at Cripple Creek. John Masson, formerly of

present name under the laws of Wyoming to avoid payment of the flat, license, and occupation tax levied by the state on all Colorado corporations, based on their capitalization. As it was necessary to make the change before March 1, and time was limited, the action was taken without consultation with the stockholders. The new company has the same officers as the old, and stock in the latter will be exchanged without delay for stock in the new corporation. The Exchange Registry & Guarantee Co. of Colorado Springs is the transfer agent named by the directors.

MAP OF CRIPPLE CREEK DISTRICT.

Broken Hill, New South Wales, will be in charge. Owen Roberts, who is operating the El Paso Gold King, has secured from the Midget-Bonanza G. M. & M. Co. a lease on the Gold hill property of the company.

The Cripple Creek district in March produced 76,054 tons of ore, valued at \$1,209,530, the largest production of the present year. The monthly report of the mills and smelters is as follows.

Plant and location.	Tonnage.	Gross bul- lion value.
Golden Cycle, Colorado City.....	32,000	\$640,000
Portland, Colorado City	10,000	215,000
Smelters, Denver and Pueblo.....	4,150	266,000
Portland, Cripple Creek district....	14,500	43,065
Colburn-Ajax, Cripple Creek district	3,100	9,920
Wild Horse, Cripple Creek district..	1,400	4,242
Jo Dandy-Cavanagh, Cripple Creek district	1,200	3,300
Stratton's Ind., Cripple Creek district	8,704	26,504
Blue Flag (est.), Cripple Creek dist.	1,000	6,000
	76,054	\$1,209,531

In a letter to stockholders the Pharmacist G. M. Co. directors explain that the company, formerly known as the Pharmacist Con. G. M. Co., was reincorporated with the

Dennis Ryan, manager of the Hunter mine in the Coeur d'Alene district, has announced in Spokane that additional equipment will be provided within 90 days to double the present output. One hundred and twenty-five men are at work in the mine and mill. The mill capacity of 300 tons per day is to be increased to 400 tons in May, and it is the intention to add a 400-ton unit this summer. Other plans are to prospect and open a body of high-grade silver-lead ore between the No. 4 and No. 6 adits.

Black Horse mine, near Murray, recently shipped a car of zinc concentrate that ran 51%, the highest grade of zinc yet forwarded from the Coeur d'Alene district. The Bunker Hill & Sullivan M. & C. Co. declared its regular monthly dividend of \$65,400 on April 4. This is the one hundred and seventy-fifth regular monthly disbursement and makes the total payment to stockholders during the present year \$251,600 and a total of \$13,421,250 to date. James F. Howarth has taken an option for 30 days at \$225,000 on the Idora Hill mine, near Wallace. The first payment of \$56,250 is due April 21. The final installment of \$112,500 is payable March 21, 1913. Mr. Howarth is said to represent Eastern investors. Directors of the Gold Leaf Con. Mines, controlling the Wisconsin, Gold Leaf, Copper Belt, and Washington properties, near Wallace, arranged at a meeting in Spokane to clear the claims of encumbrance and liquidate all debts. Officers were elected as follows: president, Fred N. Davis; vice-president, W. J. Parks; secretary-treasurer, Vince A. Day. Louis Boldue of Kellogg, is manager.

MONTANA
LINCOLN COUNTY

(Special Correspondence.)—Operations have started at the Libby Placer M. Co.'s plant on Libby creek, and the big hydraulic outfit is to be run with a double shift throughout the season. Mr. Hooten, the superintendent, arrived in town a few days ago from Butte and at once secured a force. P. J. Brophy, president of the company, is expected from Butte within a few days. The company owns nearly 1000 acres of placer ground on Libby creek, about twenty miles from here.

Libby, April 8.

NEVADA
ESMERALDA COUNTY

Guy and John Hibbs, of Montana, have bought the Reward No. 1, 2, 3, 4, and 5 claims, known as the old McNamara group, from W. H. Keenan and others. It is reported they will build a 50-ton mill, which is to be ready by July 15. The sale was effected through B. E. Thomas, of Goldfield.

NYE COUNTY

(Special Correspondence.) — The Mushett-Wittenberg lease on the Manhattan Con. confirms the report of finding a rich vein on the 130-ft. level. The lessees state the shaft will be sunk 125 ft. deeper. The ore will be treated at the Associated mill. The Steffner lease is moving the hoisting plant from the old to the new shaft. With the completion of this work it is planned to sink the 200-ft. shaft to a depth of 720 ft. A large tonnage of milling-grade quartz is blocked out in the Poak-Steen-Cicala lease workings. This lease is sending 100 tons of ore per day to the leased Lemon mill, where 45 tons per day are treated. The balance will be milled as soon as facilities permit.

Arrangements are under way for the sinking of the shaft from the 400 to the 500-ft. level. Two other leases are operating on the Big Four estate.

Manhattan, April 5.

The Associated Milling Co.'s 50-ton mill in the Manhattan district has been started and is crushing ore from the Steffner lease on the Manhattan Con. property. The Big Four M. Co. has purchased the Poak-Steen-Cieala lease on the Big Four property. The shaft will be sunk to the 500-ft. level.

Mines in the Tonopah district last week produced 8481 tons of ore, valued at \$212,025. The Tonopah Belmont was in the lead with 1950 tons. The Tonopah Extension mill during March crushed 4618 tons of ore, producing bullion valued at \$55,300. The ore averaged about \$14 per ton.

STOREY COUNTY

During the week ended April 6 the Ophir S. M. Co. produced 257 tons of ore averaging close to \$25 per ton, and shipped 400 tons second-class ore to the Kinkead mill. A carload of concentrate also was shipped to the Selby smelter. During the regular development in the Con. Virginia mine 53 tons of ore averaging \$10.87 was saved. The Mexican mill crushed 557 tons of ore which assayed an average of

arrival. In March the mill treated 3200 tons of ore; last week, 760 tons. Precipitate for the last ten days of March is being smelted. By the Socorro Mines 1200 tons of ore was milled during the week. The Treasure M. & R. Co. shipped 480 tons of ore in the week ended March 31. During March a total of 133 ft. of development was done on the Pacific mine of the Oaks Co., producing 75 tons of ore. In the course of recent development work on the Trilby group a large tonnage of ore was accumulated and is now being sent to the Deadwood mill. Should the results be satisfactory, it is likely a lease will be let.

Mogollon, April 5.

TEXAS

EL PASO COUNTY

The old Federal Copper Co. smelter, which has been idle for the past ten years, is being torn down. W. C. Greene bought the plant to treat his Chihuahua ores, but when he had to close some of his properties in 1907 he sold the smelter. When built 15 years ago the smelter was well outside of the city. Now its site will be used for residence purposes.

UTAH

JUAB COUNTY

The Chief Con. M. Co. in the first quarter of 1911 earned about \$124,300, according to recent reports. The January profit was \$13,300, that for February \$51,000, and the March profit is estimated at \$60,000.

Dividend paying properties in the Tintie district for 1910 and 1911 have been tabulated as follows by the *Salt Lake Tribune*.

Company.	1910.	1911.
Centennial-Eureka	\$600,000	\$600,000
Colorado	300,000	180,000
Gemini	10,000
Grand Central	60,000	25,000
Iron Blossom	200,000	320,000
Lower Mam. Extension.....	2,000
Ophongo	10,000
Sonix Consolidated	89,448	89,448
Uncle Sam Consolidated.....	45,000	75,000
Victoria Consolidated	10,000

Totals\$1,306,448 \$1,309,448

Some of the companies named have not yet paid dividends this year, but new producers are coming forward.

SALT LAKE COUNTY

The Utah Copper Co.'s Boston mine was shut down last Wednesday after 350 miners and trammers had walked out. The men asked an increase of 50c. per day, to \$3.50, for miners, and 25c., to \$2.75, for trammers.

SUMMIT COUNTY

The Daly West M. Co. has declared the regular quarterly dividend of 30c. per share, payable April 20, to stockholders of record April 10. The dividend will mean the disbursement of \$54,000, and will bring the dividend payments of the year to \$121,500.

CANADA

BRITISH COLUMBIA

Advices from Spokane state that it is officially announced that construction work on the 2000-ton smelter for the Granby Consolidated company at Granby Bay, Portland Canal district, will begin in May. The company plans to expend an equal amount in the development and equipment of the Hidden Creek mine. The smelter site has been graded, and the company will start work soon on the construction of a tramway to convey the ore from the mine to the smelter at tidewater.

Plans for financing the Hidden Creek property of the Granby are held up indefinitely. The Granby management is said to be very well satisfied with the prospects at the Hidden Creek mine. On the present copper market Granby can show a fair margin of profit, and it is possible that the new properties will be financed out of accumulated earn-

PART OF WESTERN NEVADA.

\$23.77. Repairing the 1600-ft. level of the mine jointly with the Sierra Nevada and Union Con. proceeded. From the 2300-ft. level 36 tons of \$59 ore, and from the 2400-ft. level 103 tons of \$29 ore were taken. The Union Con. and other properties were the scene of the usual repair and development.

WASHOE COUNTY

The Nevada Deep Mines Co. has ordered a 10-stamp mill with a capacity of 75 tons per day, for its property in the Como district, near Reno. The mine is developed to the 300-ft. level. The plant also will include tube-mills and cyanide equipment.

NEW MEXICO

SOCORRO COUNTY

(Special Correspondence.)—The Deadwood Mines plant will resume operation today. During the shut-down of the past six weeks a large tonnage of custom ore has accumulated. The new gasoline hoist of the Deep Down property has been installed and the mine crew increased. Both property and equipment are now in readiness to make regular daily deliveries of ore to the Deadwood mill. The mine is operated under lease.

The Ernestine M. Co.'s new Blake crusher has been shipped and will be placed in commission immediately on

ings, which would avoid the necessity of making a new stock issue.

Twenty-five thousand dollars, at the rate of $1\frac{1}{4}$ c. per share, payable April 10, is the amount of the first dividend declared by the Standard M. Co., operating the Standard mine in the Sloean district. The property, which is owned by Spokane and New York investors, has been under development fourteen months. John A. Finch, of Spokane, who holds the controlling interest, has with him Patrick Clark, George Aylord, W. E. Cullen, and Michael Shea.

ONTARIO

(Special Correspondence.)—The Pearl Lake Co. has now sunk the shaft to the 400-ft. level and after sinking 20 ft. farther will cross-cut to intersect the two veins. The same process is to be repeated at the 600, 800, 1000, and 1200-ft. levels. About 3500 ft. of diamond-drilling has been done on these orebodies. About 27,000 ft. of diamond-drilling has been done on the Dome property since August 1911.

The McIntyre mill has been running again on electric power supplied from Sandy Falls. The ore is fed into bins at the top of the mill and then passes through the stamp batteries, where 10 stamps, weight 1250 lb., are dropping 8 in. at the rate of 100 drops per minute. After passing over the amalgamation plates the ore is concentrated by passing over two Deister concentrating tables, and from there to three No. 3 Deister slime tables, the concentrate being stored for further treatment later on.

The Bradley company of New York has just given an order for 25 rock-drills to the McKiernan-Terry Drill Co. of New York. The order was awarded after three weeks competitive test participated in by several of the big firms. The Vipond shaft is being sunk to the 300-ft. level, and about 500 ft. of driving is being done per month. The cross-cut on the Three Nations at the 100-ft. level has now cut the vein, which looks promising.

Ontario, April 2.

The Casey Cobalt company has obtained a 5-stamp experimental mill and a 3-drill compressor. Tests will be made for five months to determine the best method of treatment for the Casey ore. At the Townsite mill at the Northern Customs concentrator, 20 stamps are being added to the present equipment, bringing the battery up to 50 stamps.

The silver production of the Cobalt district in 1911 established a new record, according to the annual report of Arthur A. Cole, mining engineer to the T. & N. O. Commission, to the Ontario legislature. Last year's production was valued at \$16,500,000, as against \$15,477,987 for the preceding year, which was the previous record. The tonnage was less than that of either 1910 or 1909, being 25,710, as against 34,710 in 1910, and 30,058 in 1909.

YUKON

Owners of copper properties at the head of the White river have been passing through Dawson on their way to start the season's operation. H. E. Morgan, owner of some promising claims, is among them. Men are said to be scarce at Whitehorse, with wages at \$5 per day and board.

CHILE

At the Braden property two units of the concentrator are in operation and a third is about to go into commission. A leaching plant is being constructed. At the same time, independently of company operations, the Mineral Separation, Ltd., of London is erecting a 250-ton plant at its own expense and expects to handle a large part of the Braden ores. This company is operating successfully in Australia and New Zealand. In the end, with very cheap power and the working out of various methods of treatment, Braden expects to produce its copper at something less than 7c. per pound, which will give it a prominent place among the low-cost coppers.

MEXICO

OAXACA

Reports in the *Mexican Herald* state that the damage done by the revolution in this state in the closing of properties, the options allowed to lapse, and general apprehen-

sion, has been great, and that the movement of capital in development and returns is about a third as large as during the days preceding the anti-Diaz revolution. The Los Oe-toes properties of the Teziutlan Copper Co. have been shut down. The Natividad mines of the Sierra Juarez have caught fire and for the past month attempts to smother the flames in the workings have been ineffectual. H. A. Monday has sold his half interest in the Dos Cabezas group to Hillsboro, Indiana, investors, who are operating. James Griffin is superintendent of the property. The A. S. & R. Co. has closed its ore-buying agency at Taviche, as the larger mines are shipping direct, and the smaller mines do not justify maintaining the office. A. R. Wren, formerly in charge at Taviche, has moved to the Monterey office. J. E. Gee and J. A. Wilkerson have taken charge of the Indiana-Oaxaca M. Co.'s properties, vice Mr. Cartens, who is now manager for the Compania Minera de Tejomuleo, a Mexican company, in the same district. Ground has been broken for the new Cubilete mill. The Andes-Bullion properties, Taviche district, have been shut down. The Santa Caterina mill is again operating, after having been closed for two years. Due to revolution or accident, only three treatment plants are operating in the state.

Among the Copper Mines

SHANNON'S production is showing an increase over that of 1911, the output for the first two months of 1912 having been 2,849,000 lb., as against 2,411,000 in the previous year. Though its cost of production has been reduced, it is still, according to latest reports, around $11\frac{1}{2}$ c. per pound.

The INSPIRATION'S new mill's first unit should be in operation within 18 months, according to an announcement by W. B. Thompson. Construction will be started within sixty days. At least 45,000,000 tons of ore averaging more than 2% copper has been proved, in addition to 15,000,000 tons partly developed.

The MIAMI COPPER CO. is mining and concentrating an average of 3000 tons of ore per day, and it is estimated that production of fine copper is close to 3,000,000 lb. per month. Development is at the rate of nearly 6000 ft. per month. All mining is being done above the 420-ft. level, but the 570-ft. level is being opened up. Pits are being dug for foundations for a tailing tower. It will be equipped with four bucket-elevators having 24-in. belts and designed to elevate the tailing 60 ft., so that the gulch into which it is now being run may be filled to the limit. This elevation will also be sufficient to run the tailing by gravity into the next gulch to the east.

NOTWITHSTANDING the national strike of the colliers and subsequent great diminution in the consumption of copper throughout England and Scotland, says James Lewis & Son's mid-monthly report on copper, the value of 'Standard' has advanced from £64 5s. for cash on March 1 to £64 15s. March 18, the sales amounting to about 21,000 tons. In face of such adverse circumstances this advance shows the exceptionally strong inherent position of this metal. A settlement of the strike would probably be followed by active buying and a further improvement in values. Large sales of electrolytic copper have been made by American producers to British consumers up to $14\frac{1}{2}$ c. per pound, and £68 per ton c.i.f. is now asked for Europe. The American Producers' returns show an increased production for the first two months of this year, as compared with the same period last year, of 4396 tons, the British consumption being 11,596 tons and the exports 20,087 tons greater. The stocks are reduced 11,837 tons in the two months, making the reduction in the American and European stocks 18,063 tons and 78,781 tons in the past twelve months. European consumption shows an increase of 14,893 tons as compared with the same period last year—58,482 tons against 43,589 tons.

Personal

Professional men are invited to send news of their engagements and travels. Such news is interesting to friends.

W. H. RADFORD has left for Alaska.

J. F. NEWSOM has gone to Montana.

E. S. BERRY is at the Braden mine, in Chile.

R. S. RAINSFORD was in San Francisco Tuesday.

R. W. PERRY has returned to Medellin, Colombia.

WILBUR E. SANDERS is at Soulsbyville, California.

J. B. WOODWORTH has returned to Toronto from Arizona.

W. E. THORNE is now at 408 Salisbury House, London, E. C.

F. L. SIZER is at Ray, Arizona, and will go to Tonopah, Nevada.

ENRIQUE VALLE is in charge of the Santa Catarina mines, at Tavihe.

R. E. CRANSTON has gone to Bodie on a two weeks professional trip.

R. B. MCGINNIS has returned from New Mexico and has gone to Oregon.

C. L. HARGRAVE has returned to Berkeley, California, from Cobalt, Ontario.

J. C. NICHOLLS is now with the Dome Mines Co., Ltd., South Porcupine, Ontario.

P. G. SPILSBURY, general manager for the Aguacate mines, has returned to Costa Rica.

A. L. QUENEAU will sail from New York on April 27 for Jemappe sur Meuse, Belgium.

C. H. SHAMEL is now at Seattle and expects soon to visit San Francisco and Los Angeles.

F. W. OLDFIELD is on his way to London and should be addressed care *The Mining Magazine*.

STANLEY C. SEARS has returned from Mexico and is at Room 104, State House, Boston, Massachusetts.

A. W. BURGREN has returned from Mexico and is now at at Pacific and Poverty Point mines at Placerville, California.

ROBERT LINTON, general manager for the Sierra Consolidated Mines Co. of Ocampo, Chihuahua, is now at Los Angeles.

JAMES NASH, who discovered the Gympie goldfield, Australia, in 1867, has been granted a pension by the Queensland Government.

Obituary

THOMAS EDWARDS, who died at Melbourne early in February, was born at Blackwater, in Cornwall, July 10, 1838. His father, who was a 'mine captain,' died soon after, and, at the age of 17, Mr. Edwards went to Australia with his uncle, who was one of the pioneer gold-seekers. The pair went to Ballarat, then at its zenith, and engaged in mining for a number of years. In 1864 while Mr. Edwards was employed by the Clunes United Co., at Clunes, he saw the desirability of improving milling methods and, securing the right of re-treatment of the tailing, erected a plant for roasting and amalgamation. In 1871 he removed to Western Australia and, with others, formed the United Pyrites Co. for roasting and amalgamating concentrate, and here first introduced the Plattner process into Australia. Later he became connected with the Mount Morgan mine, and in 1890 he erected a large ore-treatment plant at Sebastopol, Ballarat. The work here led to the invention of the Edwards furnace, which was so successful that its use has become general. He was an enthusiastic investigator and keenly interested in mining education. A shareholder in many of the principal mines of Victoria and a member of the board of several, he was also a member of learned and technical societies. He leaves three daughters, his son having died a few years previously.

Concentrates

Most of these are in reply to questions received by mail. Our readers are invited to ask questions and give information dealing with the practice of mining, milling, and smelting.

DOUBLE-RIVETED lap joints in $\frac{3}{8}$ -in. plates gives efficiencies of from 61.4 to 71.3%, according to tests.

EFFECT of vacuum upon the steam consumption of a turbine is strikingly shown by the reports of a recent test on a 1000-kw. machine in which the consumption increased 40% with a decrease in vacuum from 29 to 21 inches.

ZINC VIOLETS are scientifically known as *viola calaminaria*, and in Europe grow in particular abundance in soils containing the zinc ore, calamine, whence the derivation of the name. The same species is found at the Horn Silver mine in Utah.

ELECTROMAGNETIC separators are used for removing metallic iron from cupola slag, rubbish, and sweepings. Some old dumps contain as much as 20% iron, and in foundries 10 to 12% of the iron is lost; the foundry waste amounts to 7 to 10% of this. The average cupola slag contains 4 to 6% of iron recoverable by magnetic methods.

BRICK vary in strength, according to the method of manufacture. A soft brick will crush under 450 to 600 lb. per square inch, but a first-rate machine-pressed brick will stand 3000 to 6000 lb. per square inch, or 200 to 400 tons per square foot. The weight of brick varies from 100 lb. per cubic foot of inferior brick to 150 lb. per cubic foot for the best pressed brick.

CHLORIDES may be detected in the presence of bromides and iodines by the use of a boiling solution of $(\text{NH}_4)_2\text{C}_2\text{O}_4$, since AgCl is slightly soluble, AgBr less soluble, and AgI insoluble. By boiling the washed precipitate of silver salts for a few minutes with half-normal oxalate solution, filtering, and adding KBr to the filtrate the presence of chlorides can be detected by the occurrence of turbidity.

CEMENT, measured by the capital invested, is one of the world's three great attractive industries. In capital employed it apparently far outranks the gold-mining industry. Only coal and iron stand ahead of it. The price of portland cement in 1910 was as low as 73c. per barrel in some places, the average for the United States being 89.1c. per barrel. In 1890 the average price was over \$2 per barrel, and as late as 1903 it was \$1.24 per barrel.

EXHAUST STEAM can be used for evaporating by filling a pan 11 by 17 ft. and 18 in. deep with cast-iron condensing pipes of 250 sq. ft. of surface. By keeping the pan-room warm and letting in only enough air to carry away the vapor adds to efficiency, as the temperature in the pan will average only about 165°F. In evaporating liquids whose boiling point is much above that of water, exhaust steam can do little more than bring them to saturation, but on weak liquors it is useful.

HANDLING of the various materials is one of the most important engineering problems in every large construction job. The facility with which the concrete may be placed becomes as great an advantage as the strength and durability of the finished structure. The handling of the cement and aggregates, and the mixing and placing of the wet concrete are problems that may be readily solved by machinery, and the entire process from the raw-material bins to the forms may be made continuous and very rapid. The proper design and arrangement of the concrete-mixing plant must be determined with respect to several things. The source of the material, the treatment the material must

receive (washing, sizing, or crushing), the capacity of the plant as it bears upon the rate of progress of the work, and the manner of placing the mixed concrete, influence the design of the plant and thereby the cost of carrying on the work.

AIR-COMPRESSORS, even where the fuel-supply cost per unit is low, if the most economical commercial results are to be obtained it is necessary to consider carefully not only the design of the compressor in detail, but also the factors entering into the cost of the necessary boiler capacity installed, the cost of the compressor foundations, building, and all other factors involved in the complete installation. The annual charges, based upon the total cost of the compressor installed, for the same capacity of output, added to the cost of fuel, operation and maintenance costs, will give the proper basis for comparison and decision in the purchase of the most economical air-compressor.

KEENE'S cement is usually made by burning lump gypsum to a red heat in a small vertical kiln closely resembling those in common use for lime burning. The dehydrated sulphate of lime is immersed in a solution of alum, dried, and again burned at a high temperature. After the second burning the product is finely ground and is then ready for the market. The gypsum used for Keene's cement should be of the purest. Especially should it be free from iron, since this tends to discolor the product. As small a quantity as 0.04% of iron oxide will sometimes give red streaks in the lumps of gypsum. Large quantities of Keene's cement are imported, but its manufacture in this country has increased much of late years. Kansas and Virginia furnish large supplies. The finished product should be pure white. It sets much slower than other plasters, and should develop a tensile strength in seven days of between 600 and 700 lb. per square inch.

COAL LANDS were disposed of at the minimum price of \$10 and \$20 per acre until July 1906. At that date and since, large areas reported to contain coal have been withdrawn from all forms of entry. These withdrawn areas have been or are being classified by the United States Geological Survey through field examinations into coal and non-coal lands, and restored to entry as fast as possible. Those classified as coal lands were formerly subject to such entry only, excepting mineral locations for other minerals, and at the valuation per acre placed upon them by the Geological Survey. They may now be filed upon for coal at the valuation set, or the surface only obtained by an agricultural entry, relinquishing the coal to the Government, which may dispose of it to other parties. The basis of the valuation made by the Geological Survey is contained in the 'Regulations regarding the classification and valuation of coal lands, as approved to June 6, 1910, by the Secretary of the Interior.'

BISMUTH is one of the few metals of which the United States cannot or does not produce enough to supply its needs. The scarcity of bismuth in this country and the accredited control of the market by a foreign syndicate have kept the American price high, but according to the United States Geological Survey interest is rapidly being developed in the recovery of bismuth as a by-product in electrolytic lead refining. No large deposits of bismuth are known in the United States, but some ores mined for their gold or silver have been found to be more valuable for their bismuth than for their original content. Thus in 1910 a Colorado mine reported to the Geological Survey the production of ore which carried up to 18% of bismuth, in addition to gold and silver. The ore was smelted for the precious metals it contained, but if it had been sold for its bismuth content alone it probably would have brought at least \$185 per ton. Another Colorado mine produced during the same year ore containing 11 to 16% of bismuth, the total content of the metal amounting to several tons. Though mined for gold, this ore was more valuable for its bismuth. The imports of bismuth in 1910 were 198,174 lb., valued at \$332,668.

Company Reports

DALY-JUDGE MINING COMPANY

The report of this company for the year ended January 1, 1912, in addition to showing a satisfactory cash surplus, states that surface indications prompt the belief that the Ontario-Daly vein, already proved for 2600 ft., in the Ontario, Daly, and Daly West properties, extends through that of the Daly-Judge for its entire length, about 11,000 ft., and into the Snake Creek M. & T. Co.'s ground beyond. Since the previous report of November 1, 1911, the company has exceeded without difficulty the dividend requirements. Other data given in the report have been printed in the issues for March 23 and 30.

STANDARD CONSOLIDATED MINING COMPANY

In the thirty-third annual report of this company, for the year ended February 26, Albert Fries, president of the company, states that unless some chances are taken in pumping out the lower levels of the mine, at a considerable expense, expectations of dividends should be modest, as during the 33 years of operation most of the better-grade ore above the water-level has been mined. A threatened loss was averted, and a small profit made for the year. J. R. Buchanan, superintendent of the property, which is situated at Bodie, Mono county, California, recommended the Lent shaft as the best place for the pumping plant. Dividend No. 120, paid during the year, amounted to \$17,839, bringing the total sum disbursed in dividends by the company to \$4,329,809. Previous to the consolidation the Standard M. Co. paid \$900,000 in dividends, making the total dividends from the property \$5,229,809. The production for the year was \$235,477. The total production by the property has amounted to \$16,135,993, of which \$1,513,735 was before the consolidation. The ore mined during the year amounted to 9466 tons, of an average value of \$14.74, as against an output the preceding year of 14,528 tons averaging \$14.38. The small profit was due to unusual difficulties in operation, and it was impossible at any time to mine sufficient ore to keep the mill running at capacity.

TRINITY GOLD MINING & REDUCTION COMPANY

This company's second annual report shows that in the year ended November 30, 1911, it made a net profit of \$66,265. This sum, which was about half of the expected profit, represents about six months' operation, states the report, and it is believed a much better showing can be made when the alterations and improvements to the plant have been completed and it is running at full capacity. During the year \$25,068 was spent, on capital account, for improvements, and of this \$15,138 was on the crushing plant, mill, and buildings. Other expenditures represented in this amount were on the water-power plant, electric light and power systems, fire protection, cyanide tanks, and refining works. In the mine account, an increase of \$8863 was due to interest and other costs in carrying the borrowed money used in paying for the property. Equipment caused the expenditure of an additional \$2499. There was a net increase in the ore development account of \$6239, making a total increase in the fixed assets of the company of \$42,669. The company during the year reduced its indebtedness by \$10,930. At the end of the fiscal year the indebtedness exceeded the current assets by \$81,924, as against \$132,520 at the end of the preceding fiscal year. If the 45,500 shares of capital stock be added to this account, the excess of indebtedness over current assets is reduced to \$36,424. The earnings for the year amounted to \$207,831 and the expenses to \$141,566.

PHILIPS, DODGE & CO., INC.

This company was organized in 1908, as the successor of the firm of Phelps, Dodge & Co., with a capitalization of \$50,000,000, in shares of \$100 each. The company controls, through ownership of more than 99% of the various

stock issues, the Copper Queen Consolidated Mining Co., Moctezuma Copper Co., Detroit Copper Mining Co., Burro Mountain Copper Co., and the Stag Cañon Fuel Co., and controls indirectly the Old Dominion Co., the Old Dominion Copper Mining & Smelting Co., United Globe Mines Commercial Mining Co., and the El Paso & Southwestern railway. The report of the corporation for the year 1911 shows that during the year it sold 131,327,002 lb. of its own copper and 48,974,963 in commissions at an average price of 12.63c. per pound. Dividends amounting to \$5,400,000, or at the rate of 12% on the outstanding shares were paid. The combined reports of the constituent companies show that during 1911 ore amounting to 1,841,210 tons was extracted, of which 1,017,352 tons was melted, producing 179,234 tons of concentrate, and 930,331 tons was smelted. The production for the year was:

	Copper, lb.	Silver, oz.	Gold, oz.
From companies' ores.....	123,653,978	1,195,954	10,158
From custom ores.....	10,495,649	598,941	10,996
Total output	134,149,627	1,794,895	27,154

During the year the mercantile departments of the constituent companies were dissociated and organized into the Phelps Dodge Mercantile Co., which purchased from each company its store business and stock of merchandise. The total sales during the year amounted to \$5,317,994, on which a profit of 7.51% was made. The combined balance sheet and income statement is as follows:

ASSETS	
Cash	\$2,692,821.32
Accounts receivable	1,404,636.93
Bonds owned	81,060.00
Stocks owned:	
Copper Queen Con. Mining Co. \$27,000,000	
Moctezuma Copper Co. 8,000,000	
Detroit Copper Mining Com-	
pany of Arizona..... 6,000,000	
Stag Cañon Fuel Co. 6,500,000	
Burro Mountain Copper Co.. 2,200,000	
	\$53,878,518.25
INCOME STATEMENT, 1911	
LIABILITIES	
Due to subsidiary companies and others.....	\$3,250,143.14
Capital stock, 450,000 shares issued.....	45,000,000.00
Reserve against stocks owned.....	1,500,000.00
Surplus	4,128,375.11
	\$53,878,518.25

RECEIPTS	
Dividends received from subsidiary companies	\$6,994,000.00
Commissions and miscellaneous earnings....	289,508.52
	\$7,283,508.52
PAYMENTS	
Dividends paid	\$5,400,000.00
Expenses, taxes, etc.....	149,206.44
Transferred to:	
Reserve against stocks owned.....	1,500,000.00
Surplus account	234,302.08
	\$7,283,508.52

An interesting feature of the report is the results of the second year's workings of the Employees' Benefit Association, which had an average membership of 1500. Contributions from members during the year amounted to \$40,303, the Copper Queen Mining Co. contributing \$25,000. During the year 4.96% of the members received accident benefits and 1.37% sickness benefits, the total expenditure for this purpose being \$50,702; the expense of administration was \$1898.

On Thursday, April 4, the Bunker Hill & Sullivan M. & C. Co. paid dividend No. 175, of \$49,050. This makes the total amount of dividends paid \$13,388,550.

ARIZONA rejoices in the possession of a Canon Diabolo, according to our New York contemporary. Possibly this peculiar form of geomorphic expression may be due to the gyratory motion of the hot air of the desert.

FRENCH railway and postal authorities have made a commendable innovation in providing that after June 1 the hours of the day, from midnight to midnight, shall be numbered 1 to 24, thus preventing confusion of morning and afternoon time. Incidentally, the remark of the convivial one, "23 for mine," will acquire a new significance.

DEPENDENCE of the share markets upon men rather than on money alone was shown by the sharp decline in prices in New York when the rumor gained currency that Mr. J. P. Morgan may have been on board the *Titanic*, though the knowledge that many millionaires, among them John Jacob Astor, were among the missing had previously left the market unmoved.

RECORD extraction is being made in the mill of the Dome Mines, Ltd. According to recent advices, the tailing from the cyanide plant contains \$0.07 in gold, representing an extraction even higher than was anticipated. The mill was first started on March 21 and both the builders and the management are to be congratulated on having made so notable a record during the first month of operation.

RECEIVERS were appointed on April 6 for Allis-Chalmers Company, being Mr. D. W. Call, president of the company, and Mr. Otto H. Falk, president of the Merchants & Manufacturers Association of Milwaukee. This is probably intended to facilitate the early reorganization of the company, details of which have lately been published. The works will be operated by the receivers with no cessation of activity in any line.

OPERATION of the third unit of the Chino mill marks the completion of the plant as originally designed less than two years after the organization of the company. The first section was started in November last, and it is now planned to add two more units, bringing the capacity to 5000 tons per day. In a recent issue, Mr. J. M. Sully, manager for the company, described the mill, which, under the superintendence of Mr. W. T. McDonald, is doing excellent work. At the Ray Consolidated the March output was 2,400,000 pounds of copper, produced at a reported cost of under 9½ cents per pound. The output of ore for March was 108,700 tons, which, it is hoped, will be shortly increased to 4000 tons daily. A 70 per cent recovery of copper worth 16 cents per pound at a working cost of 9½ cents per pound represents approximately \$50,000 worth of copper going to waste monthly at the Ray Consolidated. It is allowed to go to waste, of course, because it cannot be recovered at even a much greater cost than 9½ cents per pound, but the comparison is useful in evidencing that dressing of ores of this character is a field in which large rewards may be won by further improvement of methods.

ADDITIONAL competition in the coal trade at San Francisco is probable as a result of the purchase by the United States Smelting, Refining & Mining Company of Utah coal mines, and the organization of the Western Pacific Fuel Company as a subsidiary. The mines purchased have been delivering coal to yards in Oakland, and while the purchase is assumed to have been made mainly with a view to assuring an adequate fuel supply to the smelters controlled by the parent company, some effort to expand the retail trade in coal is to be expected. Total coal sales at San Francisco, however, are not sufficiently large to allow much scope for a new company, and until coal is sold at greatly reduced prices it cannot compete on the Bay for steam-generating purposes with oil, or with hydro-electric power.

PERSISTENCE of ore-shoots in depth forms the subject of an admirable study by Mr. F. Lynwood Garrison, which was presented at the recent meeting of the Canadian Mining Institute and is reproduced elsewhere in this issue. Mr. Garrison presents much valuable evidence, and, with the true spirit of the investigator, is content to reach an inconclusive conclusion, since until the evidence is all in it is impossible to form a final judgment. Mr. Garrison refers, in passing, to a matter which has given rise to more discussion than investigation, namely, the amount and influence of ground-water in the genesis of ores. It is evident that a wide range of opinion exists among geologists regarding this question, though it might be expected that it would be one of the first to be settled, since the ground-water lies in that part of the earth's crust which is directly under our observation. Direct evidence is incomparably of more value than deduction in the study of ore deposits, as a homely example will perhaps serve to show. The percolator coffee-pot, in which hot water is forced by steam up a central tube and distributed over the ground coffee, the resulting solution passing back into the central reservoir, is a common object. It would seem obvious that where so vigorous a circulation exists the solution must be homogeneous in composition, yet it is a matter of everyday observation that the top portion of the decoction, that which has most recently passed through the coffee, is less concentrated than the bottom portion. Similarly, in the study of natural forces a small amount of reliable field evidence is worth reams of deduction.

LEGISLATION by accretion is described by H. W. MacFarren in his series of articles recounting the history of the development of the American mining law which was begun last week and is continued in this issue. California was the natal place of the mining act, though perhaps it would be more accurate to say that, like Topsy, it was not born but 'just grew.' Defects in the mining law are easily perceived now, but looking at it from the other viewpoint, and considering that it had its inception in local regulations devised by law-abiding citizens to permit orderly action in a field where Congress had provided no law, remembering that it was founded in the light of a faulty knowledge of the nature and characteristics of ore deposits, it is in some degree remarkable that the law has not proved more unsatisfactory. Much of the trouble has resulted from the fundamental defect of American judicial procedure; a defect arising from a laudable desire to prevent any citizen from being deprived of his just rights, but which has tended rather to prevent a citizen from securing his just rights within a reasonable period and at a reasonable expense. This is the right of appeal for trivial causes, frequently for no cause, and which sometimes leads to the protraction of litigation for decades. A movement is now on foot tending toward limiting the right of appeal

to those cases where evidence can be introduced to show that substantial justice has not been done, and if this result can be attained, much relief will result. Another defect of American law is legislation by accretion, due to the fact that the meaning of the law can only be determined by a series of judicial decisions. This leads to such a situation as that of the Sherman law, passed a quarter-century ago, of which the purport has only recently been made clear. Attempts to amend it are restrained by a knowledge that the significance of the amendments could only be defined after another quarter-century of judicial consideration. To criticize the law is easy, to mend it is a task of another order.

Advertising Value of Plain Truth

To the modern disciple of Epictetus no phase of life is more interesting than the general divergence of precept and practice. Among the most notable contributions to American philosophy are the Essays of Emerson, which inculcate the idea of balance and due proportion in all human emotions and activities. These are generally commended, yet modern life in its attitude toward them much resembles the man who said he was a Methodist but was not working at it. Nowhere is this more clearly emphasized, perhaps, than in the methods pursued by individuals and districts endeavoring to secure for themselves a measure of public attention—which may be designated as advertising. The word must be used semi-apologetically, since the condition to which we refer has so generally obtained that the word advertising has almost a derogatory sense except when restricted to the advertisement of wares and commodities. No better example could be desired than the practice of many communities of issuing from time to time booklets, pamphlets, and especially editions of local papers, in which the sawmill is portrayed as a magnificent industry, the store as an emporium of trade, and the prominent citizen as a distinguished capitalist or a statesman. Usually this is regarded as an evidence of the humorous American spirit of exaggeration. But the trouble with this is that it puts the whole scheme of things on the wrong footing. If statements are to be discounted 70 per cent for exaggeration, then the proprietor of a really large sawmill must describe it as a wonderful example of magnificent ingenuity and business insight, while the owner of truly important manufactory must draw upon the wealth of Oriental hyperbole to portray his business. Probably he will do nothing of the sort, but instead will take refuge in dignified silence. Thus arises a marked characteristic of the ordinary newspaper, which commonly devotes its space either to people and things so eminent that they cannot escape publicity, or else to the trivial and insignificant. The broad field between is left untouched. We are often, for example, in receipt of issues of daily or weekly journals, published in districts where there are mines of importance, only to find that all the news given bearing on the mining industry relates to some insignificant prospect, or that some drunken miner has beaten his wife. Why should the irregularities in the lives of the ignorant and vicious be regarded as of importance, except from the standpoint of securing better government? From time to time we are asked why we do not publish more authentic information regarding this or that mining district, and recently a financier and engineer of international reputation went so far as to say that he could secure four or five times as much capital for investment in the mines of a certain district if such information were available. To all such inquiries we can make but one reply; such information, news in the correct sense of the word, is not available; the companies do not give it out, and the local journals do not publish it. Yet these same communities and districts will publish bul-

letins and folders for the avowed purpose of drawing attention to their resources. Nothing is so convincing as the plain truth; nothing is so much appreciated as real information. Exaggerations serve only to discredit those who are content with the established facts. The pervasive influence of print is too seldom realized. Exchanges go far and wide and the happenings in remote places do not remain hidden. A community can have no better advertisement than the sober recital of the plain facts of the achievements of its citizens and the enterprises under their control.

Loss of the Titanic

The futility of human endeavor when it runs counter to natural forces was shown with horrible distinctness on Sunday night when the White Star liner, *Titanic*, the largest ship ever constructed, on her maiden voyage from Southampton to New York, collided with an ice-floe 400 miles off Cape Race, on the banks of Newfoundland, and sank within four hours, with two-thirds of the ship's company still on board. Passengers and crew numbered 2350, of whom less than 850 are known to have been saved. The steamer *Carpathia* was within 70 miles of the *Titanic* at the time of the disaster, and picked up boats containing the survivors, but as nearly as can be learned from the dispatches, the vessels which arrived later, summoned by wireless messages, were unable to find any of the shipwrecked kept afloat by wreckage or life preservers, all having apparently been carried down by the tremendous suction of the great vessel as she plunged to the bottom. Of the survivors nearly all are women and children, only enough men to man the boats having left the vessel. Among those supposed to have been lost are H. Forbes Julian, the well-known metallurgist, at one time technical adviser to the Deutsche Gold und Silber Scheide Anstalt and a former special contributor of the *Mining and Scientific Press*, Washington A. Roebling, president of John A. Roebling's Sons Co., who constructed the Brooklyn bridge after his father's design, Benjamin Guggenheim, one of the seven brothers of the family which has been prominent in the development of the American smelting industry, and Edgar J. Meyer, vice-president of the Braden Copper Mines Company.

Much about the loss of the vessel is likely to remain permanently unknown. The occurrence of icebergs in this vicinity is not remarkable. Eleven other vessels have been lost from the same cause in the past fifty years and it is the custom of mariners during the season when ice is most abundant to follow a route which, though longer, lies farther to the south and is correspondingly less likely to be infested with the great masses of ice which are borne far south by the Arctic current to form a silent and deadly peril. The rapidity with which the vessel filled and sank is astonishing, and is generally taken to indicate that the enormous vessel, proceeding almost at top speed, struck the ice-mass a glancing blow and tore the entire bottom of the hull so badly that water-tight compartments were rendered useless, unable even to keep the hulk afloat until nearby vessels could come to her aid. The boat accommodation was only sufficient for little more than a third of the ship's company, since shipping regulations apply only to vessels of less than 10,000 tons burden. The wireless equipment was of such a type that it was effective only over a short range and was speedily rendered useless by the stopping of the engines by the rushing water. External conditions favored the escape of the passengers; the sea was calm, help was but a few hours off, and except for the darkness and the benumbing cold of the water the conditions which led to this greatest of marine disasters

were man-made. The preceding day the *Amerika* had reported icebergs in the vicinity, yet the huge vessel, inadequately safeguarded, went rushing through the darkness to her doom—because those on board wished to reach New York as quickly as possible. It is easy to say now that three times as many boats should have been provided and that the wireless equipment should have been of the highest efficiency, and independent of the main engines. The officers of the steamship company had provided more boats than were required by law, and did not provide more still because the added weight would have diminished speed. They gave their passengers what they believed they wanted, and as a result over a thousand persons, among them many of the most notable men and women of the country, are dead. The spirit of recklessness in attaining ends, deplorable as it is, can lead to only individual injury where small forces are concerned, but where titanic energy is hurled recklessly against the Jovian resistance of natural forces the resulting disaster is appalling. It is not a compliment to modern life and thought that it requires a catastrophe such as this to make us pause and consider whither we are tending in our headlong race for size and speed.

The Copper Market

There is much interest in the copper situation, though there is considerable skepticism as to future prices. If it were not for the enormous financial strength that is known to be behind the copper market, the attitude of the public would be much more skeptical than it is. Outsiders are by no means convinced that the consumption abroad or a revival of business at home is actually absorbing the huge copper surplus that was in existence a few months ago, but which has now disappeared, according to published figures; the question remaining being as to the actual disappearance or consumption of the metal. All current comment is congratulatory in tone and descriptive of the strength of the market, and there is no little talk of the effort being made to prevent a 'runaway copper market.' Our New York correspondent states that the high price is having the expected effect of reviving interest in copper mining, and cites numerous instances.

The larger companies are making hay while the sun shines. The New York office of the Utah Copper Company reports the shipment of about 20,000 tons per day from the mine to the mills, and putting of 18,000 tons daily through the concentrators. Shares are selling in the market at practically the record price. With the improved outlook producing results such as outlined, and with properties such as Braden, Chino, Inspiration, Miami, and Ray Consolidated just getting into stride, it is plainly to be seen that, without regard to the foundations upon which the copper market is built, the metal at 16 cents is sure to bring about an era of activity in mining, and if the copper market can be held long enough, the public will buy copper stock, which is the consummation so eagerly sought in New York. The report of the Copper Producers' Association showed the situation unchanged, and has been generally passed without comment. The foreign copper authorities are taking considerable interest in the increased production shown in Russia. There is much unexplored territory under Russian dominion, and it is quite within the range of possibility that that country may become a very important producer of copper. The production for 1912 is expected to total something over 67,000,000 pounds and will be an increase of about 10 per cent over that of the preceding year. We present elsewhere a summary of the James Lewis report on the European situation as regards copper.

Decrease of Value in Ore-Shoots With Depth

By F. LYNWOOD GARRISON

*Anyone who has kept in touch with the trend of development in metal producing and especially precious-metal producing districts, must have noted with interest, if not surprise, the repeated instances of discoveries of orebodies at relatively deep points in old mines, thus infusing new life into the district and affording encouragement to operators of other mines similarly situated to explore and extend their deeper levels. In directing attention to this important and interesting subject it must be recognized that one deals with a matter of which inherent difficulties may not be lightly regarded, and from which unwarranted deductions might be drawn for promotion purposes or to deceive. It is therefore but proper to state at the outset that profitable ore deposits do not usually persist to great depths; in fact, in a geologic sense, they are essentially superficial phenomena. It is true that mineralized fissures are known to extend to depths of 6000 ft. and probably much more, but it seems likely they will seldom be sufficiently rich to pay.

The class of ore deposits considered in this paper are those in fissures that traverse crystalline rocks, or sedimentary rocks, intimately connected with rocks of a magmatic origin. These associations are almost invariably cut by intrusive dikes or sills of igneous rocks belonging to a subsequent period. The mineralization of these fissures in the process of creating veins was later than the formation of the country rock; in other words, the ore deposits here considered are epigenetic. Such fissures, when single, are termed a vein, and when grouped or bunched in a zone or belt may be considered a lode. Of course, a lode may be a single vein or no vein at all, but simply an accumulation of ore. It is recognized that the common use of the terms 'vein' and 'lode' is not altogether satisfactory, but it is not intended to suggest any rule for their application, further than as a matter of convenience within the limits of this paper. As a general fact, openings or fractures in the earth's crust decrease in size as depth is attained, and a fissure that may have a width of many feet in its upper part, if followed to sufficient depth, is likely to end in a series of small cracks whose width is measured in inches rather than in feet.¹ Fissures thus defined may not be necessarily ore bearing, or they may be too lean to pay in whole or in part. A fissure is not necessarily a vein, but a vein assumes the pre-existence of a crack or fissure. Here only such veins are considered as have had their mineral contents deposited by filling or replacement along fissures through which the metal-bearing waters and vapors have supposedly circulated.

Bedded deposits, such as the Lake Superior copper and the South African gold-bearing conglomerates, are in a class by themselves, one not considered in this discussion, although, as is well known, the workings on them are about the deepest in the world. Both carry native metals in the cementing or binding material of the conglomerates, and the orebodies are practically continuous and persistent, quite unlike the irregular, often erratic occurrences of ore-shoots in precious metal-bearing lodes. It would seem probable that the genesis of two such dissimilar types of ore deposits is as different as their physical characteristics. It is essential to bear in mind that many veins as we now find them, may be mere roots of what they once were, erosion having removed hundreds or even thousands of feet from their original upper portions. According to Lindgren,² in some of the Australian deposits, such as those at Bendigo, although carrying profitable ore as deep

as 4600 ft., the gold quartz was probably deposited therein when they were at least 7000 ft. below the original surface. Similarly he believes the gold ores of the Mother Lode, California, to have been formed at depths not less than 6000 ft. from the surface. The gold deposits of the southern Appalachians are perhaps as good examples of vein roots as are to be found. The amount of material eroded from their croppings since the time of formation Lindgren believes to be greatly in excess of those figures given for Australia and California.³ Considering that, although usually lean, these gold ores have been found and followed in the southern Appalachians to depths of over 1000 ft., their original outcrops must have had a vertical range exceeding 7000 or 8000 ft. According to Ransome, the original surface at Cripple Creek, Colorado, was probably from 2000 to 5000 ft. above the present one.⁴ In the gold districts of Nova Scotia, Faribault⁵ has estimated that the erosion of some of the sharpest and highest folds has had the effect of truncating them to a depth, so far as known, of over eight miles. The presumption here is that this vast amount of erosion has removed what was probably the best part of these gold lodes, since the mere stumps that remain have never yet proved of much value. Basing his views on the extreme narrowness of the fissures in the Cobalt mining district, Emmons concludes that the veins there were formed under the pressure of an enormous weight of superincumbent rock at a great depth below the then existing surface; hence before present conditions were reached, the greater part of the original veins had been eroded away, leaving today mere remnants of their original metal treasures. This assumption Emmons supports by a seemingly logical and convincing analysis of the geologic history of the region.⁶ Whether or not this unpromising and unwelcome view is accepted, it appears to be a fact that the change from rich to poor in the Cobalt veins is abrupt, and that this alteration takes place at depths not exceeding 300 ft.; in other words, the productive zone is seemingly shallow. Since these observations were made by Emmons, a continuation of ore-shoots from the Huronian into the Kewatin is reported which rather dispels the pessimistic view held by many that these deposits would not persist below the Huronian, that is, below 300 or 400 ft. in vertical depth. In eastern North America it is certain that the type of veins found close to the surface—that is, those cutting volcanic rocks, recent flows, the upper surface of which at the time of vein formation can be determined with more or less accuracy—is exceedingly rare. On the other hand, older veins which may intersect the intrusive rocks like diorite and granite; rocks which have surely been consolidated at great depths, and which were probably once covered by heavy masses of just such flows as above indicated, are comparatively common.⁷ It is doubtless assuming too much to conclude that a district which has been profoundly eroded like some of those mentioned, is unlikely to contain veins profitable and persistent in depth, it is impossible to know how deep the original fissures may have been; it is only possible to collect observations from a comparatively few widely scattered districts all over the world, where deep mining has been attempted. These records are ever open to suspicion, for it is never certain that a vein supposedly bottomed in lean ore or no ore at all, has not simply temporarily pinched out, to be followed lower down by another shoot as good as any

found higher up. Undoubtedly many, possibly most, veins in which such conditions have been encountered are hopeless as far as profitable working is concerned. But the difficulty is to be certain in such cases that a vein or lode is done for all time, and may not perchance again blossom into full bloom of productivity. The probabilities are, however, that in the majority of cases veins or lodes do decrease in richness below 1000 to 1500 ft. This cannot always be safely accepted as a rule, save it be one with many exceptions.

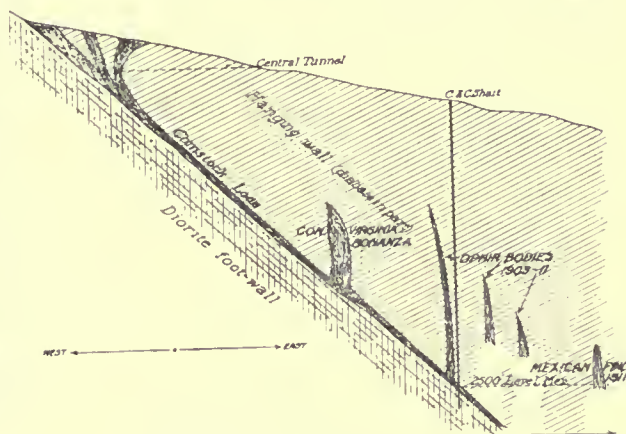

It is well known that the North American continent has been relatively stable since the close of the Cretaceous period, and that its land surfaces are older than those of Europe; I refer more particularly to those of the eastern half of North America. Suess has pointed out that the land surfaces of Africa are far older than either North America or Europe. Africa has as yet produced no great vein or lode deposits of the first rank; the gold 'basket' of the Transvaal not belonging to the class under discussion. The lodes of Rhodesia have been on the whole disappointing, while none of the modern gold mines of Egypt have ever paid a dividend and most of the concessions taken up in 1900 and 1901 have been abandoned.⁸ As before intimated, these suggestive observations may be foolish if carried too far, in view of the present very incomplete knowledge of Africa, for it is a vast continent, but slightly explored in the geologic sense, and may yet yield highly productive ore deposits of the class under consideration. The undoubted great yield of gold from Africa in ancient times was the result of slave labor, a brutal bondage probably unsurpassed in history. It is an interesting reflection in this connection that it was slave labor which made the gold deposits of the southern Appalachians profitably productive, and that, on the whole, attempts to operate them have been financial failures in modern times with free labor. The consequent thought from the trend of these observations is that in cases where great areas have been subjected for long geologic periods to erosion by virtue of their stability, the planing down of the surface has been so great that little is left today of the original deposits in the old rocks. While such generalizations must evidently be accepted with the greatest caution, there does seem to be some relation between the vertical extent of metal lodes and the geologic age of the area in which they occur. In other words, the more stable an area has been through its geologic history the greater the erosion to which it has been subjected, and the less productive have been its mineral lodes.

Instances of the discovery of new deep-seated ore-shoots are not uncommon in well established metal-producing districts where systematic exploration and development are being carried on. A number of such cases might be cited, including the famous Comstock and some of the old mines on the Mother Lode in California. At Guanajuato, Mexico, the lower reaches of the Valenciana lode on the Veta Madre are to be tapped at a vertical depth of 2000 ft. below the collar of the Nueva Luz shaft, and about 3300 ft. on the dip of the vein from the top of the old Valenciana shaft, by new workings, with a reasonable assurance of finding large bodies of payable ore. The Mexican Government, doubtless after obtaining professional advice, has had sufficient confidence in the success of this undertaking to grant a subsidy to the American company doing the work for each metre of depth attained in this new (Nueva Luz) shaft; the expectation being that the orebodies thus opened for exploitation and the incidental unwatering of the old Valenciana workings will bring new life to this once enormously productive district. I believe this is the only instance in which the Mexican Government has directly given such pecuniary aid to a mining enterprise, showing thereby confidence in the persistence with depth of this great mother lode.

In Australia the Victoria Reef Quartz mine at Bendigo has attained a vertical depth of over 4600 ft., but as the orebody at this level is too lean to pay, it has been de-

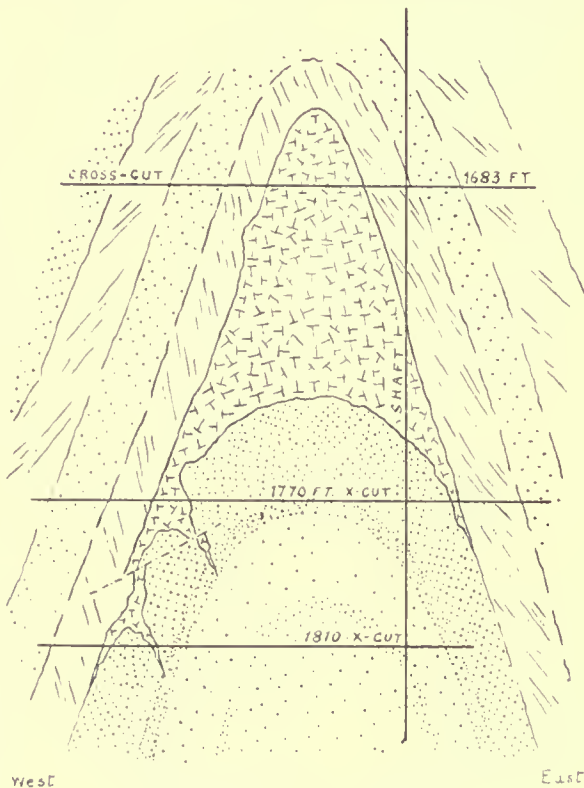

cided to sink to a depth of 5254 ft., the Government bearing half the cost. Between the 4254 and 4154-ft. levels considerable coarse gold was found, some pieces weighing a half-ounce after passing through the stamps. The average of the ore was about \$17 per ton. The gold itself has not decreased in purity nor was it in unusually fine particles, as had been expected. This is situated centrally on the famous New Chum lode, from which many millions of dollars have been obtained.⁹

H. Kilburn Scott, in the June 1911 issue of *The Mining*

CROSS-SECTION OF COMSTOCK LOPE.

Magazine, calls attention to the Morro Velho mine in Brazil, belonging to the St. John Del Rey Mining Co., Ltd., as the deepest gold mine in the world. He states he recently had occasion to visit this mine, and found it almost 5000

NEW CHUM CONSOLIDATED LOPE.

ft. in vertical depth; the ore has an approximate dip of 45°, so that the depth along the slope is about 7000 feet.

It is evident there exists among experienced mining people a belief that in profoundly mineralized regions it is reasonable to expect that the deep sections of great vein systems will continue to yield abundantly of their treasures whenever the costs of exploration and extraction are not prohibitive. According to H. C. Hoover, at Kalgoorlie, Western Australia, there are several properties upon which orebodies have been discovered in depth where none or but small ones

⁹Wilfred J. Rickard, *The Mining Magazine*, Oct. 1910, p. 281.

existed at the surface. In other instances in this district a marked increase of value has been noted with depth.¹⁰ This paper of Hoover's was written eight years ago, and whether this last characteristic has been maintained I do not know; the latest reliable information obtainable is to the effect that several of the deeper mines in the Kalgoorlie district are producing abundantly at the 2600 to 2800-ft. levels. Hoover considers that the profound structural features of the district are such that this width and continuity of the fissures are well assured, but that the ore will occur continuously with the lodes "is a matter which admits of less finality."¹¹

Lindgren likewise says these deposits have no definite boundaries, either horizontally or vertically, other than those determined by the decrease of assay value of the rock in any one direction.¹² It would be a mistake to draw any general conclusion from conditions at Kalgoorlie. They are not unique, though perhaps unusual. There seems to be little reason to assume that depth below the surface has *per se* any direct relation to the extent and richness of the lodes. Recent experience at Tonopah, Nevada, tends to show a decrease in value with depth with a compensating tendency to wide lateral extent of profitable ore in the veins, limited only by the characteristic block faulting of the district. However, it is not to be inferred from this that a vein, or lode, or series of veins is necessarily continuous laterally through the full extent of such a block. Evidently such is not the case, for the veins appear to cease laterally as they do in depth, even before being cut by a fault or intrusive dike. But the practical point in this instance is that the chances of finding ore are overwhelmingly greater in lateral exploration than in vertical. An interesting classical case may be cited in this connection. At Joachimsthal, Bohemia, the veins have been divided into two classes, first, those rich in the upper levels but which grow poorer with depth; and, second, those fissures that are of fairly constant and persistent value as deep as 2000 ft. A peculiarity of the latter class is that some of the fissures reach the surface, not as mineralized veins, but as narrow barren cracks.¹³ A number of years ago W. P. Blake observed that when a lode cuts different formations its contents must be expected to change with the varying character of the rocks, either downward or horizontally. The change in Cornwall, England, from copper ore to tin ore in passing from 'killas' into granite is a good and classic example of this. When lodes traverse stratified rocks parallel with bedding, the conditions as respect the chemical constitution of the walls may be assumed to be alike for great distances, and therefore similar mineral contents may be looked for as far as these conditions extend. But when the lode traverses a group of beds transverse to the bedding, uniformity of mineralization either in quantity or quality need not be expected.¹⁴

The old German miners recognized the value of pyrite as an indication of the proximity of ore; they gave the name *fahlbands* to zones or belts of pyritized country rock, and observed that fissures intersecting such zones are usually locally enriched. For example, in the Kongsberg mine at Kongsberg, Norway, the ore-shoots are usually, but not invariably, confined to the *fahlbands*. A short distance from these zones the veins are apt to be barren. This famous old silver mine is now probably about 3000 ft. or more in vertical depth, and has been a great producer since the year 1623. Most of the silver is in the native condition. It has been assumed, and I think logically, that the metaliferous portions of this interesting lode are the consequence of the associated *fahlbands*. Intimate associations of pyrite and native silver have also been observed in several Mexican mines, and the inference has been drawn in such cases that

the pyrite was in some way connected with the presence of native silver.¹⁵ At Batopilas, according to Collins, the native silver occurs with calcite, but below the pyritic zone.¹⁶ On the Mother Lode in California it has been observed that pyrite does not appear to have been the direct precipitating agent for gold, but to have facilitated its precipitation by acting as a depository or base for the precipitate. Instances have been noted where the gold appears to have been precipitated upon the pyrite in preference to associated quartz. The same influence that precipitates the gold seems to have also precipitated the pyrite. The quantity of pyrite in solution, being in excess of the gold, is naturally precipitated out first.¹⁷

A remarkable instance of the apparent influence of pyrite upon gold deposition has been noted by Scott at the Morro Velho mine in Minas Geraes, Brazil. He states that this great lode consists of lenticular shoots of quartz enclosed in schists. They follow the cleavage or bedding of the enclosing rock; the quartz is often associated with arsenical pyrite, pyrrhotite, and carbonates of lime, magnesium, and iron. When these sulphides are lacking, gold in appreciable quantity is entirely absent. The most productive matrix is a compact mixture of quartz and pyrite enclosing varying quantities of country rock. The Morro Velho lode shows little appreciable difference in size or gold value throughout its great depth. The enclosing rock, though generally speckled with pyrite at the contact, contains only a small amount of gold. The pure quartz in the lode is seldom auriferous, and the pure pyrite (unless it be arsenical) is hardly ever rich.¹⁸ According to Derby, the Morro Velho lode was characterized by the presence of free carbon, either disseminated throughout the ore or segregated in zones of movement.¹⁹

Among the minor causes of enrichment of ore deposits near the surface is the mingling of solutions from cross fissures. Van Hise attributes the principal cause of ore-shoots to them and it is indisputable that at such intersections orebodies are common. But it does not appear that bonanzas or local enrichments in deep lodes are necessarily dependent upon such influences; in fact, deep-seated ore-shoots are generally characterized by comparative dryness. As a rule the deeper the less water there is; in other words, it would seem in most instances that after a certain level has been passed the amount of water encountered varies in inverse ratio with the depth, the deepest workings being the driest.
